SIMPLE VECTOR BUNDLES ON PLANE DEGENERATIONS OF AN ELLIPTIC CURVE

LESYA BODNARCHUK, YURIY DROZD, AND GERT-MARTIN GREUEL

Abstract. In 1957 Atiyah classified simple and indecomposable vector bundles on an elliptic curve. In this article we generalize his classification by describing the simple vector bundles on all reduced plane cubic curves. Our main result states that a simple vector bundle on such a curve is completely determined by its rank, multidegree and determinant. Our approach, based on the representation theory of boxes, also yields an explicit description of the corresponding universal families of simple vector bundles.

1. Introduction

The theory of vector bundles on an elliptic curve and its degenerations is known to be closely related with the theory of integrable systems (see e.g. [Kri77, Ma78, Mu94]). Another motivation for studying vector bundles on elliptic fibrations comes from the work of Friedman Morgan and Witten [FMW99], who discovered their importance for heterotic string theory. The main motivation of our investigation was the following problem. Let $\mathbb{E} \to T$ be an elliptic fibration, where $T$ is some basis such that for any point $t \in T$ the fiber $\mathbb{E}_t$ is a reduced projective curve with trivial dualizing sheaf.

In most applications, a generic fiber of this fibration is an elliptic curve and for the points of the discriminant locus $\Delta \subset T$ the fibers are singular (and possibly reducible). Can one give a uniform description of simple vector bundles both on the smooth and the singular fibers?

It is known that the category of all vector bundles of a singular genus one curve $E$ essentially depends on the singularity type of the curve. For example, in the case of the Weierstraß family $\mathbb{E} \to \mathbb{C}^2$ given by the equation $zy^2 = 4x^3 + g_2xz^2 + g_3z^3$, the

\[ \begin{array}{c}
\mathbb{E} \\
T
\end{array} \]
cuspidal fiber $E = \mathbb{P}_{(0,0)}$ is vector-bundle-wild whereas all the other fibers $E = \mathbb{P}_{(g_2, g_3)}$ (smooth and nodal) are vector-bundle-tame. This phenomenon seems to be rather strange, since very strong continuity results for the Picard functor are known to be true [AK79]. It is one of the results of this paper that the situation is completely different if one restricts to the study of the simple vector bundles. Namely we prove that the category $\mathbb{VB}_E$ of simple vector bundles on $E$ is indeed tame. Moreover, we provide a complete classification of simple bundles and describe a bundle on the moduli space, having certain universal properties.

The starting point of our investigation and the main source of inspiration was the following classical result of Atiyah.

**Theorem 1.1 ([Ati57]).** Let $E$ be an elliptic curve over an algebraically closed field $\mathbb{k}$. Then a simple vector bundle $\mathcal{E}$ on $E$ is uniquely determined by its rank $r$, degree $d$, which should be coprime, and determinant $\det(\mathcal{E}) \in \text{Pic}^d(E) \cong E$.

The main result of our article generalizes Atiyah’s theorem to all reduced plane degenerations of an elliptic curve.

Singular fibers of elliptic fibered surfaces were described by Kodaira and throughout this article we make use of his classification, see for example [BPV84, Table 3, p.150]. In what follows the cycles of projective lines (also called Kodaira cycles) are denoted by $I_N$, where $N$ is the number of irreducible components. Note that a Kodaira cycle $I_N$ is a plane curve if and only if $N \leq 3$. Besides them, there are precisely three other Kodaira fibers. Thus, we study simple vector bundles on the following six configurations:

In order to present our main theorem, let us fix some notations. Throughout this article, let $\mathbb{k}$ be an algebraically closed field, and a curve $X$ be a reduced projective curve. Let $E$ be a plane degeneration of an elliptic curve, $N = 1, 2, 3$ the number of its irreducible components and $L_k$ the $k$-th component of $E$. For a vector bundle $\mathcal{E}$ on $E$ we denote

- $d_k = d_k(\mathcal{E}) = \deg(\mathcal{E}|_{L_k}) \in \mathbb{Z}$ the degree of the restriction of $\mathcal{E}$ on $L_k$;
- $d = d(\mathcal{E}) = (d_1, \ldots, d_N) \in \mathbb{Z}^N$ the multidegree of $\mathcal{E}$;
- $d = \deg(\mathcal{E}) = d_1 + \cdots + d_N$ the degree of $\mathcal{E}$. In our cases it is equal to the Euler-Poincaré characteristic: $\chi(\mathcal{E}) = h^0(\mathcal{E}) - h^1(\mathcal{E})$;
- $r = \text{rank}(\mathcal{E})$ the rank of $\mathcal{E}$.

Moreover, let $\text{Pic}^d(E)$ be the Picard group of invertible sheaves of multidegree $d$ on $E$. The following theorem generalizes Atiyah’s classification and is the main result of this article.

---

1 In representation theory a category is called **tame** if its indecomposable objects can be described by some discrete and one continuous parameters, and **wild** if they are non-classifiable. An algebraic variety $X$ is called vector-bundle-wild or vector-bundle-tame if the category $\mathbb{VB}_X$ of vector bundles on $X$ is wild or respectively tame (see [DG01]).

2 A bundle is called simple if it admits no endomorphisms but homotheties.

3 Note that $\text{Pic}^d(E)$ is $E$ for an elliptic curve, $\mathbb{k}$ for Kodaira cycles and $\mathbb{k}^*$ for the other Kodaira fibers.
Theorem 1.2. Let $E$ be a reduced plane cubic curve with $N$ irreducible components, $1 \leq N \leq 3$.

(i) Then the rank $r$ and the degree $d$ of a simple vector bundle on $E$ are coprime. For any tuple of integers $(r, d) \in \mathbb{N} \times \mathbb{Z}^N$ such that $\gcd(r, d_1+\cdots+d_N) = 1$, let $\mathcal{M} = \mathcal{VB}^r_E(r, d)$ be the set of simple vector bundles of rank $r$ and multidegree $d$. Then the map $\operatorname{det} : \mathcal{M} \to \operatorname{Pic}^d(E)$ is a bijection.

(ii) The Jacobian $\operatorname{Pic}^{(0,\ldots,0)}(E)$ acts transitively on $\mathcal{M}$. The stabilizer of a point is isomorphic to $\mathbb{Z}_r$ if $E$ is a Kodaira cycle, and is trivial in the remaining cases.

Let $\Lambda := k^*$ if $E$ is a Kodaira cycle and $\Lambda := k$ if $E$ is a Kodaira fiber of type II, III or IV. By [1.2] (i) $\Lambda$ is a moduli space of simple vector bundles of given rank $r$ and multidegree $d$ provided $\gcd(r, d) = 1$. By an observation of Burban and Kreußer [BK4], for a given tuple of integers $(r, d) \in \mathbb{N} \times \mathbb{Z}^N$ such that $\gcd(r, d) = 1$, our method yields an explicit construction of a vector bundle $P = P(r, d) \in \mathcal{VB}_{E \times \Lambda}$ satisfying in the general case only the following universality properties:

- for any point $\lambda \in \Lambda$ the vector bundle $P(\lambda) := P|_{E \times \{\lambda\}} \in \mathcal{VB}(E)$ is simple of rank $r$ and multidegree $d$;
- for any vector bundle $E \in \mathcal{VB}^r_E(r, d)$ there exists a unique $\lambda \in \Lambda$ such that $E \cong P(\lambda)$;
- for two points $\lambda \neq \mu$ from $\Lambda$ we have $P(\lambda) \not\cong P(\mu)$.

If the curve $E$ is irreducible, the vector bundle $P$ is the universal family of stable vector bundles of rank $r$ and degree $d$.

Similarly to Atiyah’s proof [Ati57], the main ingredient of our approach is a construction of various bijections $\mathcal{VB}^r_E(r, d) \to \mathcal{VB}^{r'}_E(r', d')$, where $r' < r$. However, our method is completely different from Atiyah’s. We use a reduction of our classification problem to the description of bricks in the category of representations of a

| $N$ | Kodaira cycles | Kodaira fibers |
|-----|----------------|----------------|
| $N = 1$ | $I_1: y^2z = x^3 + x^2z$ | $II: y^2z = x^3$ |
| $N = 2$ | $I_2: z^3 = xyz$ | $III: y^2z = x^2y$ |
| $N = 3$ | $I_3: xyz = 0$ | $IV: xy^2 = x^2y$ |
certain box (or a differential biquiver). Moreover, we provide an explicit algorithm (algorithm 7.2) that for a given tuple \((r, d) \in \mathbb{N} \times \mathbb{Z}^N\) constructs a canonical form of a matrix, describing the universal family of simple vector bundles of rank \(r\) and multidegree \(d\). The core of this algorithm is the automaton of reduction, which is given for each of the listed curves and operates on discrete parameters like Euclidean algorithm.

For a rather long time (till the middle of the 70s) there were no efficient methods for studying moduli spaces of vector bundles of higher ranks on singular curves. In order to study vector bundles on (possibly reducible) projective curves with only nodes or cusps as singularities, Seshadri introduced the concept of the so-called parabolic bundles (see [Ses82, Section 3]). This approach was later developed by Bhosle, who introduced the notion of generalized parabolic bundles [Bho92, Bho96].

Our method of studying vector bundles on genus one curves is a certain categorification of the language of parabolic bundles of Seshadri and Bhosle. It was originally proposed in [DG01], see also [BDG01] and [BBDG] for some further elaborations. The idea of this method can be explained as follows. Let \(X\) be a singular reduced projective curve (typically rational, but with arbitrary singularities), \(\pi: \tilde{X} \to X\) its normalization. Then a description of the fibers of the functor \(\pi^*: \text{VB}_X \to \text{VB}_{\tilde{X}}\) can be converted to some representation theory problem, called a matrix problem. The main application of this method concerns the case of curves of arithmetic genus one. In the case of a cycle of \(N\) projective lines (Kodaira cycles \(I_N\)), the obtained matrix problem turns out to be representation-tame, see [Bon92] and [CB89]. As a result, it allows to obtain a complete classification of indecomposable torsion free sheaves on these genus one curves, see [DG01] and [BBDG].

However, a description of the exact combinatorics of simple vector bundles on a cycle of projective lines requires some extra work. This was done in [BDG01], but the resulting answer was not very explicit. For the case of a nodal cubic curve \(zy^2 = x^3 + x^2z\), in [Bur03] Burban derived the statement of Theorem 1.2 using the classification of all indecomposable objects. In this article we give an improved description of simple vector bundles on cycles \(I_1, I_2\) and \(I_3\) using the technique of the so-called small reductions of matrix problems.

As we have mentioned above, the representation-theoretic properties of the category of torsion free sheaves on Kodaira cycles and the other degenerations of elliptic curves are rather different. For example, for a cuspidal rational curve \(zy^2 = x^3\) even the classification of indecomposable semi-stable vector bundles of a given slope is a representation-wild problem. However, if we additionally impose the simplicity assumption, then the wild fragments of the matrix problem disappear and we can reduce the matrices to a canonical form (see [BD03]).

The matrix problems describing simple vector bundles on nodal and cuspidal cubic curves are relatively easy to deal with, since they are self-reproducing, i.e. after applying one step of small reduction we obtain the same problem but with matrices of smaller sizes. In fact, the matrix reduction operates on discrete parameters of vector bundles as Euclidean algorithm. Carrying this out we obtain the statement of Theorem 1.2 for irreducible degenerations of an elliptic curve. Unfortunately, the
matrix problems for curves with many components are no longer self-reproducing. However, they turn out to be such in some bigger class of matrix problems. To study this class in a conceptual way we need more sophisticated methods from representation theory. Namely, we describe our matrix problem as the category of representations of a certain box (also called bocs, “bimodule over a category with a coalgebra structure” or differential biquiver) see [Bod07].

The technique of boxes is known to be very useful for proving tame-wild dichotomy theorems and various semi-continuity results, see [Dro79], [Dro01], [Dro05], [CB90] etc. A new feature, illustrated in this article, is that the formalism of boxes can be very efficiently applied for constructing canonical forms of representations “in general position”. A usual approach to a matrix problem is a consecutive application of a minimal edge reduction, which is a reduction of a certain block to its Gauß form. However, since we are interested in bricks it turns out that it is sufficient to take into account only small reductions, which are Gauß reductions provided that the rank of the block is maximal. This way for each plane singular cubic curve and the matrix problem corresponding to the family of simple vector bundles of rank $r$ and multidegree $\mathbb{CS}$ we get an explicit algorithm constructing its canonical form. The course of the construction is given as a path on some automaton, whose states are boxes and transition arrows are small reductions.

To put our results in a broader mathematical context we would like to mention that the case of singular curves of genus one is special in many respects. We are especially interested in the study of vector bundles on curves having trivial dualizing bundle. This automatically implies that they have arithmetic genus one, but not vice versa. In [FMW99] Friedman, Morgan and Witten proposed a powerful method of constructing vector bundles on irreducible genus one curves and elliptic fibrations, based on the technique of the so-called spectral covers. Later, it was realized that their construction can be alternatively described using the language of Fourier-Mukai transforms, see e.g. [BK05], [BHM02], [HLSP]. Although for irreducible cubic curves Theorem 1.2 was previously known and can be proven using either geometric invariant theory or Fourier-Mukai transforms, our approach has one particular advantage. Namely, it yields a very explicit description of a universal family of simple vector bundles, which turned out to be important in applications. In particular, it was used to get new solutions of the associative and quantum Yang-Baxter equations, see [Pol07] and [BK4, Section 8].

We should also mention that the geometric point of view suggests to replace the simplicity condition by Simpson stability. Both notions are closely related for curves of arithmetic genus one. By this method in [Lo05] and [Lo06] López-Martin described geometry of the compactified Jacobian in case of Kodaira fibers and elliptic fibrations.

**Organization of the material.** In Section 2 we recall the construction of [DG01], and replace the category of vector bundles $\mathbb{VB}_E$ by the equivalent category of triples $\mathbb{Tr}_E$. Fixing bases of triples we turn to the category of matrices $\mathbb{MP}_E$. In Sections 3 and 4 this procedure is applied to all the curves from Table 1. In Section 5 we study the properties induced by the simplicity condition and obtain some additional
restrictions for the matrix problem $\text{MP}_E$. In Section 6 we fix discrete parameters $(r, d)$, and reduce a brick-object of $\text{MP}_E(r, d)$ to its partial canonical form. Remarkably, this new matrix problem and its dimension vector $s$ are completely determined by the curve $E$ the rank $r$ and the multidegree $d$. In Tables 2–4 we provide this correspondence for the curves with many components.

In Section 7 we provide a formal approach: we interpret a matrix problem as the category of bricks $\text{Br}_A(s)$ of some box $A$ and dimension vector $s$. We prove that any break is a module in a general position, thus the Gauß reduction can be replaced by the small one. A course of reduction can be presented as a path on some automaton, where states are matrix problems and transitions are small reductions. We call a box principal if $\text{Br}_A(s) \cong \text{VB}_E^s(r, d)$. For fixed rank $r$ and multidegree $d$, if the set $\text{Br}_A(s)$ is nonempty, then there is a path $p : A \to A'$, where $A'$ is principal, reducing the dimension vector $s$ to $(1, 0, \ldots, 0)$:

$$
\begin{align*}
\text{VB}_E^s(r, d) & \cong \\
\text{Br}_A(s) & \sim \\
p & \sim \\
\text{Br}_A'(1, 0, \ldots, 0).
\end{align*}
$$

A transition operates on the pair $(d \mod r, r - d \mod r)$ as Euclidean algorithm and for $E \in \text{VB}_E^s(r, d)$ we obtain $\gcd(r, d) = 1$. It turns out that this condition is not only necessary but also sufficient for $\text{VB}_E^s(r, d)$ to be nonempty. The canonical form of a brick from $\text{Br}_A(s)$ can be recovered by reversing the path $p$. The whole procedure is emphasized in algorithm 7.2.

In Sections 8–10 we construct automatons for each Kodaira cycle $I_N$ ($N \leq 3$) and show that a path on it also encodes a course of reduction for the Kodaira fiber with $N$-components.

Analyzing how a path operates on the dimension vector $s$ we deduce the first part of Theorem 1.2. In Section 11 we illustrate algorithm 7.2 on some concrete examples. In Section 12 we describe the action of $\text{Pic}^{(0,\ldots,0)}(E)$ on $\text{VB}_E^s(r, d)$ and morphisms between simple bundles, thus deduce the second part of the Theorem 1.2.

2. General approach

**Category of triples.** Let $k$ be an algebraically closed field $\overline{k}$. $\text{Sch} := \text{Sch} / \overline{k}$ the category of Noetherian schemes over $\overline{k}$ and for any scheme $T \in \text{Sch}$ by $\text{VB}_T$, $\text{TF}_T$ and $\text{Coh}_T$ we denote the categories of vector bundles, torsion free coherent and coherent sheaves on $T$ respectively.

Let $X$ be a singular curve over $\overline{k}$. Fix the following notations:

- $\pi : \widetilde{X} \to X$ the normalization of $X$;

---

4 A brick or a schurian object is a representation with no nonscalar endomorphisms.

5 Although the construction of triples and many classification results are valid for an arbitrary field, the matrix problems that we obtain can be quite special and require different methods to deal with. In order to get a uniform description for all cases we assume from the beginning the ground field $k$ to be algebraically closed.
• \( \mathcal{O} := \mathcal{O}_X \) and \( \tilde{\mathcal{O}} := \mathcal{O}_{\tilde{X}} \) the structure sheaves of \( X \) and \( \tilde{X} \) respectively;
• \( \mathcal{J} = \text{Ann}_\mathcal{O}(\pi_*\tilde{\mathcal{O}}/\mathcal{O}) \) the conductor of \( \mathcal{O} \) in \( \pi_*\tilde{\mathcal{O}} \);
• \( \iota : S \hookrightarrow X \) the subscheme of \( X \) defined by the conductor \( \mathcal{J} \) and \( \tilde{\iota} : \tilde{S} \hookrightarrow \tilde{X} \) its scheme-theoretic pull-back to the normalization \( \tilde{X} \).

Altogether they fit into a cartesian diagram:

\[
\begin{array}{ccc}
\tilde{S} & \overset{\iota}{\longrightarrow} & \tilde{X} \\
\downarrow{\tilde{\pi}} & & \downarrow{\pi} \\
S & \overset{\iota}{\longrightarrow} & X
\end{array}
\]

(1)

Remark 2.1. 1. In what follows we shall identify the structure sheaf \( \mathcal{O}_T \) of an artinian scheme \( T \) with the coordinate ring \( \mathbb{Z}[T] \).
2. The main property of the conductor is: for \( \tilde{\mathcal{J}} := I_{\tilde{S}} \) we have \( \mathcal{J} = \pi_*\tilde{\mathcal{J}} \).
3. Let \( F \in \text{Coh} X \) and \( \tilde{F} \in \text{Coh} \tilde{X} \) be coherent sheaves on \( X \) and \( \tilde{X} \) respectively. With a little abuse of notation one can write:

\[
\begin{align*}
\tilde{\iota}^*F & = F \otimes_{\mathcal{O}_S} \mathcal{O}_S = F/\mathcal{J}F \in \text{Coh} S \\
\tilde{\iota}^*\tilde{F} & = \tilde{F} \otimes_{\tilde{\mathcal{O}}_{\tilde{S}}} \tilde{\mathcal{O}}_{\tilde{S}} = \tilde{F}/\tilde{\mathcal{J}}\tilde{F} \in \text{Coh} \tilde{S}.
\end{align*}
\]

Since \( S \) and \( \tilde{S} \) are schemes of dimension zero, \( \iota_*\tilde{\iota}^*F \) and \( \tilde{\iota}_*\tilde{\iota}^*\tilde{F} \) are skyscraper sheaves on \( X \) and \( \tilde{X} \) respectively.

The usual way to deal with vector bundles on a singular curve is to lift them to the normalization, and then to work on a smooth curve, see for example [Ses82, Bho92, Bho96]. To describe the fibers of the map \( \text{VB}_X \rightarrow \text{VB}_{\tilde{X}} \) we recall the following construction:

Definition 2.2. The category of triples \( \text{Tr}_X \) is defined as follows:

• Its objects are triples \((\tilde{F}, \mathcal{M}, \tilde{\mu})\), where \( \tilde{F} \in \text{VB}_{\tilde{X}}, \mathcal{M} \in \text{VB}_S \) and \( \tilde{\mu} : \tilde{\pi}^*\mathcal{M} \rightarrow \tilde{\iota}^*\tilde{F} \) is an isomorphism of \( \mathcal{O}_{\tilde{S}} \)-modules.

• A morphism \((\tilde{F}, \mathcal{M}, \tilde{\mu}) \rightarrow (\tilde{F}', \mathcal{M}', \tilde{\mu}')\) is given by a pair \((F, f)\), where \( F : \tilde{F} \rightarrow \tilde{F}' \) is a morphism in \( \text{VB}_{\tilde{X}} \) and \( f : \mathcal{M} \rightarrow \mathcal{M}' \) is a morphism in \( \text{Coh}_S \), such that the following diagram commutes in \( \text{Coh}_S \):

\[
\begin{array}{ccc}
\tilde{\pi}^*\mathcal{M} & \overset{\tilde{\mu}}{\longrightarrow} & \tilde{\iota}^*\tilde{F} \\
\downarrow{\tilde{\pi}^*f} & & \downarrow{\tilde{\iota}^*f} \\
\tilde{\pi}^*\mathcal{M}' & \overset{\tilde{\mu}'}{\longrightarrow} & \tilde{\iota}^*\tilde{F}'.
\end{array}
\]

(2)

Raison d’être for the formalism of triples is the following theorem:

Theorem 2.3 ([DG01]). The functor \( \Psi : \text{VB}_X \longrightarrow \text{Tr}_X \) taking a vector bundle \( F \) to the triple \((\tilde{F}, \mathcal{M}, \tilde{\mu})\), where \( \tilde{F} := \pi^*F, \mathcal{M} := \iota^*\tilde{F} \) and \( \tilde{\mu} \) is the canonical morphism \( \tilde{\mu} : \tilde{\pi}^*\tilde{F} \rightarrow \tilde{\pi}^*\pi^*F \) is an equivalence of categories.
Although the statement of Theorem 2.3 holds for arbitrary reduced curves, the method based it can be efficiently used mainly for rational curves, since in this case the description of vector bundles on the normalization is well understood.

**Vector bundles on a projective line.** According to the classical result known as the Theorem of Birkhoff-Grothendieck, a vector bundle \( \tilde{\mathcal{F}} \) on a projective line \( \mathbb{P}^1 \) splits into a direct sum of line bundles:

\[
\tilde{\mathcal{F}} \cong \bigoplus_{n \in \mathbb{Z}} (\mathcal{O}_{\mathbb{P}^1}(n))^r_n.
\]

Let \((z_0 : z_1)\) be homogeneous coordinates on \( \mathbb{P}^1 \). Then an endomorphism \( F \) of \( \tilde{\mathcal{F}} \) can be written in a matrix form:

\[
F = 
\begin{pmatrix}
\ddots & 0 & \ldots & 0 & 0 \\
\cdots & F_{m1} & \ldots & 0 & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
\cdots & F_{m1} & \ldots & F_{mm} & 0 \\
\end{pmatrix},
\]

where \( F_{mn} \) are blocks of sizes \( r_m \times r_n \) with coefficients in the vector space

\[
\text{Hom}_{\mathbb{P}^1}(\mathcal{O}_{\mathbb{P}^1}(n), \mathcal{O}_{\mathbb{P}^1}(m)) \cong \mathbb{k}[z_0, z_1]_{m-n},
\]

since a morphism \( \mathcal{O}_{\mathbb{P}^1}(n) \to \mathcal{O}_{\mathbb{P}^1}(m) \) is determined by a homogeneous form \( Q(z_0, z_1) \) of degree \( m-n \). In particular, the matrix \( F \) is lower-block-triangular and the diagonal \( r_n \times r_n \) blocks \( F_{nn} \) are matrices over \( \mathbb{k} \). The morphism \( F \) is an isomorphism if and only if all the diagonal blocks \( F_{nn} \) are invertible.

**Matrix problem \( MP_X \).** To classify vector bundles on a rational projective curve \( X \) with the normalization \( \overline{X} = \bigsqcup_{k=1}^{N} L_k \) one should describe iso-classes of objects in \( \text{Tr}_X \). Note that two triples \((\tilde{\mathcal{F}}, \mathcal{M}, \tilde{\mu})\) and \((\tilde{\mathcal{F}}, \mathcal{M}', \tilde{\mu}')\) are isomorphic only if \( \tilde{\mathcal{F}} \cong \tilde{\mathcal{F}}' \) and \( \mathcal{M} \cong \mathcal{M}' \). By Birkhoff-Grothendieck theorem a bundle \( \tilde{\mathcal{F}} \) on \( \overline{X} \) can be given by a tuple of integers \( \pi := \{r(n, k)|n \in \mathbb{Z}, 1 \leq k \leq N\} \). Let \( MP_X := \bigcup_{\pi} MP_X(\pi) \) be the following Krull-Schmidt category: an object of a stratum \( MP_X(\pi) \) is a matrix \( \tilde{\mu} \) for which there exists a triple \((\tilde{\mathcal{F}}, \mathcal{M}, \tilde{\mu}) \in \text{Tr}_X \) and the vector bundle \( \tilde{\mathcal{F}} \in \text{VB}_{\overline{X}} \) splits into a direct sum of line bundles with the tuple of multiplicities \( \pi \). For two objects \( \tilde{\mu} \) and \( \tilde{\mu}' \) with triples \((\tilde{\mathcal{F}}, \mathcal{M}, \tilde{\mu})\) and \((\tilde{\mathcal{F}}', \mathcal{M}', \tilde{\mu}')\) respectively, a morphism from \( \tilde{\mu} \) to \( \tilde{\mu}' \) is a pair \((i^*F, \pi^*f)\) such that \( i^*F \cdot \tilde{\mu} = \tilde{\mu}' \cdot \pi^*f \), where \( F \in \text{Hom}_X(\tilde{\mathcal{F}}, \tilde{\mathcal{F}}') \) and \( f \in \text{Hom}(\mathcal{M}, \mathcal{M}') \). The functor \( \text{H} : \text{Tr}_X \to MP_X \) is full and dense and there is a natural projection

\[
\text{Hom}_{\text{Tr}_X}((\tilde{\mathcal{F}}, \mathcal{M}, \tilde{\mu}),(\tilde{\mathcal{F}}, \mathcal{M}, \tilde{\mu}')) \to \text{Hom}_{MP_X}((\tilde{\mu}, \tilde{\mu}')).
\]

**Definition 2.4.** Replacing the set of morphisms by the set of invertible morphisms in \( MP_X(\pi) \) (also called matrix transformations) we obtain some groupoid. A matrix problem is the problem of describing orbits of indecomposable (respectively simple) objects. If it is possible, a solution consists in finding a canonical form of \( \tilde{\mu} \).
The precise description of this procedure can be found in [Bod07]. For convenience we choose \( k \)-bases of \( \mathcal{O}_S \) and \( \mathcal{O}_{\tilde{S}} \) and rewrite \( \tilde{\mu}, \tilde{r}^*F \) and \( \tilde{\pi}^*f \) as tuples of matrices over \( k \).

3. Matrix problem for cycles of projective lines.

Let \( E \) be a cycle of \( N \) projective lines. The normalization \( \tilde{E} \) is a disjoint union of \( N \) copies of \( \mathbb{P}^1 \). For example, for \( N = 3 \) we have:

\[
\begin{array}{c}
\infty \\
0 \\
L_1 \downarrow \pi \downarrow L_2 \\
L_3 \\
\infty \\
\end{array}
\]

Let \( s_1, \ldots, s_N \) be the intersection points ordered in such a way that \( s_k \) and \( s_{k+1} \) belong to the component \( L_k \) for \( k = 1, \ldots, N - 1 \) and the points \( s_N \) and \( s_1 \) lay on \( L_N \). On each component \( L := L_k \) choose the local coordinates such that the preimages of \( s_k \) and \( s_{k+1} \) on \( L_k \), for \( k = 1, \ldots, N - 1 \), and \( s_N \) and \( s_1 \) on \( L_N \) have coordinates \( 0 := (0 : 1) \) and \( \infty := (1 : 0) \). Then

\[
\mathcal{O}_S = k(s_1) \oplus \cdots \oplus k(s_N) \quad \text{and} \quad \mathcal{O}_{\tilde{S}} = \bigoplus_{k=1}^N (k(0_k) \oplus k(\infty_k)).
\]

To describe vector bundles on \( E \) for a triple \((\tilde{\mathcal{F}}, \mathcal{M}, \tilde{\mu})\) we fix:

- a splitting \( \tilde{\mathcal{F}} \cong \bigoplus_{k=1}^N \left( \bigoplus_{n \in \mathbb{Z}} \mathcal{O}_{L_k}(n)^{r(n,k)} \right) \) with \( \sum_{n \in \mathbb{Z}} r(n,k) = r \);
- an isomorphism \( \mathcal{M} \cong \mathcal{O}_{\tilde{S}}^N = (\bigoplus_{k=1}^N k(s_k))^r \).
- The choice of coordinates on each component \( L \) of \( \tilde{X} \) fixes two canonical sections \( z_0 \) and \( z_1 \) of \( H^0(\mathcal{O}_L(1)) \), and we use the following trivializations

\[
\mathcal{O}_L(n) \otimes \mathcal{O}_L^{\mathcal{O}_{\tilde{S}}} \cong k(0) \times k(\infty)
\]

\[
\zeta \otimes 1 \mapsto (\zeta/z_0^n(0), \zeta/z_0^n(\infty)).
\]

This isomorphism only depends on the choice of coordinates on \( L \cong \mathbb{P}^1 \). In such a way we equip the \( \mathcal{O}_{\tilde{S}} \)-module \( \tilde{r}^*\tilde{\mathcal{F}} \), where \( \tilde{r}^*\tilde{F}|_L = \tilde{F}|_L(0) \oplus \tilde{F}|_L(\infty) \), with a basis and get isomorphisms \( \tilde{\mathcal{F}}|_L(0) \cong \bigoplus_{n \in \mathbb{Z}} k(0)^{r_n} \) and \( \tilde{\mathcal{F}}|_L(\infty) \cong \bigoplus_{n \in \mathbb{Z}} k(\infty)^{r_n} \).

Matrix problem MP\(_E\) for Kodaira cycles \( I_N \). With respect to all the choices the maps \( \tilde{\mu}, \tilde{r}^*F \) and \( \tilde{\pi}^*f \) can be written as matrices.

- The gluing map \( \tilde{\mu} : \tilde{\pi}^*\mathcal{M} \rightarrow \tilde{r}^*\tilde{\mathcal{F}} \) can be given by \( 2N \) matrices over \( k \)

\[
(7) \quad \tilde{\mu} = \left( \mu_1(0), \mu_1(\infty), \mu_2(0), \mu_2(\infty), \ldots, \mu_N(0), \mu_N(\infty) \right).
\]

From the definition of the category of triples it follows that a vector bundle on \( E \) corresponds to a tuple \( \tilde{\mu} \) such that all its matrices \( \mu_k(0) \) and \( \mu_k(\infty) \) are square and invertible.
If we have a morphism $O_L(n) \to O_L(m)$ given by a homogeneous form $Q(z_0, z_1)$ of degree $m - n$, then it induces a map $O_L(n) \otimes O_S \to O_L(m) \otimes O_S$ given by $(Q(0), Q(\infty)) := (Q(0 : 1), Q(1 : 0))$. Hence, with respect to the chosen trivializations of $O_L(n)$ at 0 and $\infty$ the map $\tilde{i}^* F|_L = (F^k(0), F^k(\infty)) : k^r(0) \oplus k^r(\infty) \to k^r(0) \oplus k^r(\infty)$ is given by a pair of lower block triangular matrices $(F^k(0), F^k(\infty))$ consisting of blocks $F^k_{mn}(0), F^k_{mn}(\infty) \in \text{Mat}_k(r(m, k) \times r(n, k))$, for $m > n$ and with common diagonal blocks $F^k_{mn} \in \text{Mat}_k(r(n, k) \times r(n, k))$. The morphism $F$ is invertible, if all the diagonal blocks $F^k_{mn}$ belong to $\text{GL}(k, r(n, k))$.

The same holds for the induced map $\tilde{\pi}^* f = (f_1, \ldots, f_N)$: if $(F, f)$ is invertible then $f_k \in \text{GL}(k, r)$ for each component $k$.

The transformation rule $\mu \mapsto (\tilde{i}^* F) \cdot \mu \cdot (\tilde{\pi}^* f)^{-1}$ can be rewritten for each component $k$ as $\mu_k(0) \mapsto F_k(0) \mu_k(0) f_k^{-1}$, and $\mu_k(\infty) \mapsto F_k(\infty) \mu_k(\infty) f_k^{-1}$ assuming $f_0 = f_N$. It can be sketched as follows:

Matrices $\mu_k(0)$ and $\mu_k(\infty)$ are simultaneously divided into horizontal blocks labelled by integers, called weights. A pair of such blocks with the same weight are called conjugated and have the same number of rows. These types of matrix problems are well-known in representation theory. They are called Gelfand problems or representations of bunches of chains (see [GP68, Bon92]). For an application of Gelfand problems to the classification of torsion free sheaves on cycles of projective lines we refer to [DG01] (see also [BBDG]).

4. Matrix problem for Kodaira fibers II, III and IV

In this section we formulate the matrix problem $\text{MP}_E$ for the other curves from the Table 1. Let $E$ be a Kodaira fiber with $N$ ($N \leq 3$) components. Let $s$ be the
unique singular point and \( \pi : \tilde{E} \to E \) the normalization map. For example, for \( N = 3 \) we have

\[
\begin{array}{c}
L_1 \quad 0 \quad 0 \quad \pi \\
\hline
L_2 \quad 0 \quad 0 \quad E
\end{array}
\]

Note that \( \tilde{E} \) consists of a disjoint union of \( N \) projective lines. On each component \( L_k \) choose coordinates \((z_0 : z_1)\) such that the preimage of the singular point \( s = (0 : 0 : 1) \) on \( L_k \) is \( 0 := (0 : 1) \). Let \( U_k = \{(z_0 : z_1) | z_1 \neq 0\} \) be affine neighborhoods of 0 on \( L_k \) with local coordinates \( t_k := z_0/z_1 \) for \( k = 1, \ldots, N \); and let \( U \) be the union \( \bigcup_{k=1}^{N} \pi(U_k) \). Let us calculate the normalization map \( O \hookrightarrow \pi_* \tilde{O} = \pi_* \left( \bigoplus_{k=1}^{N} O_{L_k} \right) \), the conductor \( \mathcal{J} \) and the structure sheaves \( O_S \), and \( \tilde{O}_S \) for each Kodaira fiber:

II. Let \( E \) be a cuspidal cubic curve in \( \mathbb{P}^2 \) given by the equation \( x^3 - y^2z = 0 \). Then locally the normalization map is \( \mathbb{k}[U] = \mathbb{k}[t^2, t^3] \hookrightarrow \mathbb{k}[t] \). Since on \( \pi(U) \) the conductor is \( \mathcal{J} = \langle t^2, t^3 \rangle \), we have \( O_S \cong \mathbb{k}(s) \) and \( \tilde{O}_S \cong (\mathbb{k}[\varepsilon]/\varepsilon^2)(s) \).

III. Let \( E \) be a tacnode curve given by the equation \( y(z^2 - x^2) = 0 \). Then the normalization map is \( \mathbb{k}[U] \hookrightarrow \mathbb{k}[t_1] \oplus \mathbb{k}[t_2] \) taking \( 1 \mapsto (1, 1) \), \( x \mapsto (t_1, t_2) \), and \( y \mapsto (0, t_2^2) \). On \( \pi(U) \) for the conductor we have \( \mathcal{J} = \langle (t_1^2, 0), (0, t_2^2) \rangle \). In other words, the ideal sheaf of the scheme-theoretic preimage of \( s \) is \( \tilde{\mathcal{J}} = \left( \mathcal{I}_{L_1,0}^2, \mathcal{I}_{L_2,0}^2 \right) \), where \( \mathcal{I}_{L_k,0} \) denotes the ideal sheaf of the point 0 on the component \( L_k \). Hence, \( O_S \cong \tilde{O}/\tilde{\mathcal{J}} = O_1/\mathcal{I}_{L_1,0}^2 \oplus O_2/\mathcal{I}_{L_2,0}^2 \). Altogether we get \( O_S \cong (\mathbb{k}[\varepsilon]/\varepsilon^2)(s) \), and \( \tilde{O}_S \cong (\mathbb{k}_1[\varepsilon_1]/\varepsilon_1^2)(\tilde{s}_1) \oplus (\mathbb{k}_2[\varepsilon_2]/\varepsilon_2^2)(\tilde{s}_2) \) and the induced map \( O_S \hookrightarrow \tilde{O}_S \) takes \( \varepsilon \) to \( (\varepsilon_1, \varepsilon_2) \).

IV. Let \( E \) be a curve consisting of three concurrent projective lines in \( \mathbb{P}^2 \), given by the equation \( xy(x - y) = 0 \). Then the normalization map is \( \mathbb{k}[U] \hookrightarrow \mathbb{k}[t_1] \oplus \mathbb{k}[t_2] \oplus \mathbb{k}[t_3] \), sending \( 1 \mapsto (1, 1, 1) \), \( x \mapsto (t_1, t_2, 0) \), and \( y \mapsto (t_1, 0, t_3) \). Since \( \mathcal{J}(U) = \langle x^2, y^2, xy \rangle \), we have \( O_S = \mathbb{k}[x, y] / \langle x^2, y^2, xy \rangle \). Note that the ideal sheaf \( \tilde{\mathcal{J}} := \pi^* \mathcal{J} \) is locally generated by \( (t_1^2, 0, 0), (0, t_2^2, 0) \) and \( (0, 0, t_3^2) \) i.e. \( \tilde{\mathcal{J}} = \left( \mathcal{I}_{L_1,0}^2, \mathcal{I}_{L_2,0}^2, \mathcal{I}_{L_2,0}^2 \right) \), where \( \mathcal{I}_{L_k,0} \) is as above. Hence, \( O_S \cong \tilde{O}/\tilde{\mathcal{J}} \cong \bigoplus_{k=1}^{3} O_{L_k}/\mathcal{I}_{L_k,0}^2 \).

**Generalities for matrix problems MP\(_E\) for Kodaira fibers II, III and IV.**

For a triple \( (\tilde{\mathcal{F}}, \mathcal{M}, \tilde{\mu}) \) we fix:

- a splitting \( \tilde{\mathcal{F}} \cong \bigoplus_{k=1}^{N} \left( \bigoplus_{n \in \mathbb{Z}} O_{L_k}(n) \right)^{r(n,k)} \) with \( \sum_{n \in \mathbb{Z}} r(n,k) = r \);
- an isomorphism \( \mathcal{M} \cong \tilde{O}_S \);
- for each component \( L := L_k \) we take the trivializations \( O_L(n) \otimes O_L/\mathcal{I}_{L,0}^2 \to \mathbb{k}[\varepsilon]/\varepsilon_k^2 \),

\[
\zeta \otimes 1 \mapsto pr(\zeta/n^{1/h})
\]
for a local section \( \zeta \) of \( \mathcal{O}_L(n) \) on the open set \( U_k \), where the projection \( \text{pr} : \mathbb{k}[U_k] \rightarrow \mathbb{k}[\varepsilon_k]/\varepsilon_k^2 \) is the map induced by \( \mathbb{k}[t_k] \rightarrow \mathbb{k}[\varepsilon_k]/\varepsilon_k^2 \), mapping \( t_k \mapsto \varepsilon_k \).

With respect to all these choices in terms of matrices we have:

- The map \( \tilde{\mu} \) can be written as a combination of \( 2N \) \( r \times r \)-matrices over \( \mathbb{k} \):

\[
\tilde{\mu} = (\mu_1, \ldots, \mu_N) = \left( \mu_1(0) + \varepsilon_1 \cdot \mu_{\varepsilon_1}(0), \ldots, \mu_N(0) + \varepsilon_N \cdot \mu_{\varepsilon_N}(0) \right).
\]

The morphism \( \tilde{\mu} \) is invertible if and only if all \( \mu_k(0) \), for \( k = 1, \ldots, N \), are invertible.
- If on a component \( L \) we have a morphism \( \mathcal{O}_L(n) \rightarrow \mathcal{O}_L(m) \) given by a homogeneous form \( Q(z_0, z_1) \) of degree \( m-n \), then the induced map \( \mathcal{O}_L(n) \otimes \mathcal{O}_S \rightarrow \mathcal{O}_L(m) \otimes \mathcal{O}_S \) is given by the map

\[
\text{pr}(Q(z_0, z_1)/z_1^{m-n}) = Q(0 : 1) + \varepsilon \frac{dQ}{dz_0}(0 : 1).
\]

Hence, for a morphism \((F, f) : (\tilde{F}, \mathcal{M}, \tilde{\mu}) \rightarrow (\tilde{F}', \mathcal{M}', \tilde{\mu}')\) the induced map \( \tilde{\iota}^*F : \tilde{\iota}^*\tilde{F} \rightarrow \tilde{\iota}^*\tilde{F}' \) on each component \( L := L_k \) is

\[
\tilde{\iota}^*F|_L = F_k(0) + \varepsilon \frac{dF_k}{dz_0}(0) \in \text{Mat}(\mathbb{k}[\varepsilon]/\varepsilon^2, r),
\]

where, as usual, \( F(0) \) denotes \( F(0 : 1) \).
- The morphism \( \tilde{\iota}^*f \) consists of \( N \) copies of the matrix \( f \), where
  - \( f \in \text{Mat}(\mathbb{k}, r \times r) \) for the cuspidal cubic;
  - \( f = f(0) + f_{\varepsilon}(0) \in \text{Mat}(\mathbb{k}[\varepsilon]/\varepsilon^2, r \times r) \), for \( \varepsilon = (\varepsilon_1, \varepsilon_2) \) for the tacnode curve;
  - \( f = f(0) + x \cdot f_x(0) + y \cdot f_y(0) \in \text{Mat}(\mathbb{k}[x, y]/\langle x^2, y^2, xy \rangle, r \times r) \) for the three lines through a point in a plane (Kodaira fiber IV).

A morphism \((F, f)\) is an automorphism if and only if all \( F_k(0) \) for \( k \in \{1, \ldots, N\} \) and \( f(0) \) are invertible \( r \times r \) matrices over \( \mathbb{k} \).

For example, for the Kodaira fiber IV we get the following matrix problem. There are six \( r \times r \) matrices \( \mu_1(0), \mu_{\varepsilon_1}(0), \mu_2(0), \mu_{\varepsilon_2}(0) \) and \( \mu_3(0), \mu_{\varepsilon_3}(0) \), where all \( \mu_k(0) \) are invertible. The pairs \( \mu_k(0), \mu_{\varepsilon_k}(0) \) are simultaneously divided into horizontal
blocks labelled by integers called *weights*.

If we restrict this problem on the first two components and assuming \( f_y(0) = 0 \) and \( f_x := f_x(0) \) we obtain the problem for a tacnode curve. If we restrict the problem to the first component with \( f_y(0) = f_x(0) = 0 \) we get the problem for the cuspidal cubic curve. Each of this problems is wild even for two horizontal blocks, see [Dro92, Section 1]. However, the simplicity condition of a triple \((\tilde{F}, \mathcal{M}, \tilde{\mu})\) imposes some additional restrictions making the problem tame.

5. Simplicity condition

A vector bundle on a curve \( X \) is called *simple* if it admits no endomorphisms but homotheties, i.e. \( \text{End}_X(\mathcal{F}) = k \) and the subcategory of simple vector bundles is denoted by \( \text{VB}_X^s \). This notion can be obviously translated to the language of triples. In terms of matrix problems: an object \( \tilde{\mu} \) of \( \text{MP}_X \) is called a *brick* if \( \text{End}_{\text{MP}_X}(\tilde{\mu}) = k \). The full subcategory of bricks is denoted by \( \text{MP}_X^s \) and \( \text{MP}_X^s(\mathbb{D}) \) if the dimension vector \( \mathbb{D} \) is fixed. Note that a nonscalar morphism \((F, f)\) can have a scalar restriction \((\tilde{\tau}^* F, \pi^* f)\).

**Lemma 5.1.** Let \( X \) be a rational singular curve and \((\tilde{F}, \mathcal{M}, \tilde{\mu}) \in \text{Tr}_X \) be a triple. Then the map \( \text{End}_{\text{Tr}_X}(\tilde{F}, \mathcal{M}, \tilde{\mu}) \to \text{End}_{\text{MP}_X}(\tilde{\mu}) \) is bijective if and only if for all the components \( L \) of \( \tilde{X} \) and for all summands \( \mathcal{O}_L(n) \oplus \mathcal{O}_L(m) \) of \( \tilde{F}|_L \) the canonical maps \( \text{Hom}(\mathcal{O}_L(n), \mathcal{O}_L(m)) \to k[\mathbb{S} \cap L], \) taking \( Q \mapsto \tilde{\tau}^* Q \), are bijective.

This obvious lemma implies certain nice properties for a matrix problem under the simplicity condition. For instance, we have the following:

**Lemma 5.2.** Let \( E \) be a Kodaira fiber \( I_N \), (for \( N \in \mathbb{N} \)) II, III or IV, and let \((\tilde{F}, \mathcal{M}, \tilde{\mu}) \in \text{Tr}_X \) be a simple triple. Then for each component \( L := L_k \) \((1 \leq k \leq N)\) we have

\[
\tilde{F}|_L = (\mathcal{O}_L(n_k))^{r-d_k} \oplus (\mathcal{O}_L(n_k + 1))^{\bar{d}_k}
\]

for some \( n_k \in \mathbb{Z} \) and \( 1 \leq \bar{d}_k \leq r \).
Proof. Assume that $\pi^*F|_L$ contains a summand $O_L(n) \oplus O_L(m)$ with $m \geq n + 2$. Let $(z_0 : z_1)$ be the local coordinates as in Section 3 and 4. Since the degree $m - n \geq 2$ there exists a nonzero homogeneous form $Q \in \text{Hom}_L(O_L(n), O_L(m)) \cong k[z_0, z_1]_{m-n}$ such that $\tau^*Q = 0$. Indeed, if $E$ is a Kodaira cycle then $\tau^*Q = (Q(0), Q(\infty))$ and if $E$ is a Kodaira fiber of type II, III or I then the restriction of $\tilde{J}$ to the component $L$ is $I_{L,0} \subset O_{L,0}$ and thus $\tau^*Q = Q(0) + \frac{\partial Q}{\partial z_0}(0)$. In both cases the map $Q \mapsto \tau^*Q$ is not injective and we get a contradiction to the condition of Lemma 5.1. □

Remark 5.3. Note that the twists $n_k$ do not affect the matrix problem. Hence we can assume that the blocks have weights 0 and 1 for each component $L_k$ and replace the multidegree $/CS$ by $(\bar{d}_1, \ldots, \bar{d}_N)$ and the degree $d$ by $\bar{d} := \bar{d}_1 + \cdots + \bar{d}_N$, where $\bar{d}_k = d_k \mod r$. Having the twists $n_k$ we can recover the multidegree of $d$ by the rule $d_k = r \cdot n_k + \bar{d}_k$.

6. Primary reduction.

Applying condition (10) to the matrix problem $MP_E$ we obtain that each matrix consists of at most two horizontal blocks. Despite of this simplification the problem remains quite cumbersome. However, it can be reduced to a partial canonical form, such that all its matrices but one consist of identity and zero blocks. We denote by $M$ the remaining nonreduced matrix and formulate for it a new matrix problem. It seems reasonable to introduce some simplified system of notations.

- Let $\mathbb{I}$ denotes the identity blocks, 0 the zero blocks,
- use the star $*$ to denote nonreduced blocks and small Latin letters for a finer specification.

The matrix $M$ is divided into blocks, the set of column-blocks coincides with the set of row-blocks and is denoted by $I = \{1, 2, \ldots |I|\}$. Then $s = (s_1, \ldots, s_{|I|}) \in \mathbb{N}^I$ is the dimension vector of $M$.

6.1. Nodal cubic curve. According to Section 8 the matrix problem $MP_E$ for the nodal cubic curve $E$ and on two blocks is as follows:

\[
\begin{pmatrix}
F(0) & f \\
\mu(0) & \mu(\infty)
\end{pmatrix}
\]

Since the normalization consists of a unique component $L$ we skip the indices by $F, f$ and $\mu$. As it was mentioned above both matrices $\mu(0)$ and $\mu(\infty)$ are invertible. We reduce one of them, say $\mu(0)$, to the identity form:

\[
\mu(0) = \begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix} \quad \text{and} \quad M := \mu(\infty) = \begin{pmatrix}
a_1 & b \\
c & a_2
\end{pmatrix}.
\]
To preserve $\mu(0)$ unchanged we assume $f = F(0)$. Reformulate the problem for the matrix $M := \mu(\infty)$. The transformation rule is $M \mapsto SM(S')^{-1}$, where

$$(S, S') := (F(\infty), F(0)) = \begin{pmatrix} w_1 & 0 & w_1 & 0 \\ u & w_2 & v & w_2 \end{pmatrix}.$$
Transformations \((F, f)\) preserving the reduced matrices \(\mu_1(0), \mu_2(0)\) and \(\mu_2(\infty)\) unchanged satisfy the equations

\[
    f_1 = F_1(0), \quad f_2 = F_2(0) \quad \text{and} \quad F_2(\infty)\mu_2(\infty) = \mu_2(\infty)f_1.
\]

This implies the following triangular structures for \(F_1(0)\) and \(F_2(\infty)\):

\[
F_1(0) = \begin{pmatrix} w_1 & 0 & 0 & 0 \\ x_{21}w_2 & 0 & 0 & 0 \\ x_{31} & 0 & w_3 & 0 \\ x_{41}x_{42} & x_{43} & w_4 & \end{pmatrix} \quad \text{and} \quad F_2(\infty) = \begin{pmatrix} w_1 & 0 & 0 & 0 \\ x_{31}w_3 & 0 & 0 & 0 \\ x_{21} & 0 & w_2 & 0 \\ x_{41}x_{43} & x_{42} & w_4 & \end{pmatrix}.
\]

Since the diagonal blocks of \(F_k(0)\) and \(F_k(\infty)\) coincide (for \(k = 1, 2\)), we also have:

\[
F_1(\infty) = \begin{pmatrix} w_1 & 0 & 0 & 0 \\ x_{12}w_2 & 0 & 0 & 0 \\ y_{31}y_{32} & y_{33} & w_3 & 0 \\ y_{41}y_{42} & x_{43} & w_4 & \end{pmatrix} \quad \text{and} \quad F_2(0) = \begin{pmatrix} w_1 & 0 & 0 & 0 \\ x_{31}w_3 & 0 & 0 & 0 \\ z_{21}z_{23} & w_2 & 0 & 0 \\ z_{41}z_{43} & x_{42} & w_4 & \end{pmatrix}.
\]

**Reduced matrix problem.** Thus we obtain a new problem for the matrix \(B := \mu_1(\infty)\) with the transformations \(M \mapsto SM(S')^{-1}\), where \((S, S') := (F_1(\infty), F_2(0))\). Note that if the sizes of blocks 1 and 4 are both nonzero then taking a nonzero entry \(x_{41}\) of the matrices \(F_2(\infty)\) and \(F_1(0)\) we obtain a nonscalar endomorphism. Hence, there are no sincere bricks and the maximal tuples of blocks are \(I = (1, 2, 3)\) and its dual \(I = (2, 3, 4)\). The dimension vector \(s = (s_1, s_2, s_3)\) and the matrix problem are determined by \(r\) and \((\bar{d}_1, \bar{d}_2)\), where \(\bar{d}_k = d_k \mod r\) and \(d = \bar{d}_1 + \bar{d}_2\), as follows:

| condition | set \(I\) | dimension vector \(s\) | state |
|----------|----------|-----------------|-------|
| 1. \(r \geq d\) | \((1,2,3)\) | \((r-d, d_2, d_1)\) | \(A^+\) |
| 1'. \(r < d\) | \((2,3,4)\) | \((r-d_1, r-d_2, d-r)\) | \(A^-\) |

*Table 2.*
where $A^+$ denotes the problem $M \mapsto SM(S')^{-1}$, on the set of blocks $I = \{i_1, i_2, i_3\}$ with

$$M = \begin{pmatrix} a_1 & \ast & \ast & i_1 \\ \ast & \ast & a_2 & i_2 \\ \ast & \ast & a_3 & i_3 \end{pmatrix} \quad (S, S') = \begin{pmatrix} i_1 & i_2 & i_3 \\ i_1 w_1 & 0 & 0 \\ i_2 w_2 & 0 & * \\ i_3 * & w_3 & * \end{pmatrix} ;$$

in accordance with our notations, the problem $A^- :$ is $M \mapsto SM(S')^{-1}$, on the set of vertices $I = \{i_1, i_2, i_3\}$, where

$$M = \begin{pmatrix} i_2 & i_1 & i_3 \\ a_2 & \ast & \ast & i_2 \\ \ast & \ast & a_3 & i_3 \end{pmatrix} \quad (S, S') = \begin{pmatrix} i_2 & i_1 & i_3 \\ i_2 w_2 & 0 & * \\ i_1 * & w_1 & * \\ i_3 * & w_3 & * \end{pmatrix} .$$

Note that since matrices $S$ and $S'$ are low triangular, both problems $A^+$ or $A^-$ can be recognized by the form of the matrix $M$.

6.4. Tacnode curve. Analogously as in the previous case, we reduce the matrix $\mu_1(0)$ to the identity form and the matrix $\mu_2(0)$ to the form (11). Then for the transformations we have the restrictions:

$$f(0) = F_1(0) \quad \text{and} \quad F_2(0)\mu_2(0) = \mu_2(0)f(0) ,$$

and consequently $F_1(0)$ is as in (13). By the transformation $f_\varepsilon$ we can reduce one of the matrices $\mu_{\varepsilon_1}(0)$ or $\mu_{\varepsilon_2}(0)$, say $\mu_{\varepsilon_2}(0)$, to the zero form. In the remaining matrix $M := \mu_{\varepsilon_1}(0)$ : the blocks (31), (32), (41) and (42) can be reduced to zero by the transformation $\frac{dF_1}{dx_0}(0)$ and the blocks (21), (23), (41) and (43) can be killed by $f_\varepsilon$.

Reduced matrix problem. Thus we obtain a new problem for the matrix $M$ with the transformations $M \mapsto SMS^{-1}$ modulo zero block-entries of $M$ : 

$$M := \mu_{\varepsilon_1}(0) = \begin{pmatrix} a_1 & b_{12} & b_{13} & b_{14} \\ 0 & a_2 & 0 & b_{24} \\ 0 & 0 & a_3 & b_{34} \\ 0 & 0 & 0 & a_4 \end{pmatrix} \quad \text{and} \quad S := F_1(0) = \begin{pmatrix} w_1 & 0 & 0 \\ x_{21} & w_2 & 0 \\ x_{31} & 0 & w_3 \\ x_{41}x_{42} & x_{43} & w_4 \end{pmatrix} .$$

It is easy to see that if the sizes of blocks 1 and 4 are both nonzero then there is a nontrivial endomorphism. As in the previous case there are no sincere bricks and the admissible tuples of blocks $I$ and sizes $s$ are the same as in Table 2 whereas the
configurations $A^+$ and $A^-$ are respectively the matrix problems with

$$M = \begin{bmatrix} a_1 & * & * \\ a_2 & * & w_1 \\ a_3 & * & w_2 \end{bmatrix} \quad \text{and} \quad M = \begin{bmatrix} a_2 & * & w_2 \\ a_3 & * & w_3 \\ a_4 & * & w_4 \end{bmatrix}.$$

We replaced the zero-blocks by the empty spaces, since they do not play a role in calculations, and thus such notation seems to be more appropriate.

**Example 6.1.** Let $E$ be a Kodaira fiber $I_2$ or $III$ and $(\tilde{F}, \tilde{\mathcal{M}}, \tilde{\mu})$ be a triple corresponding to a simple vector bundle. If $r \geq \bar{d}$ then the matrix $\tilde{\mu}$ can be respectively transformed to the form

$$\begin{bmatrix} 1 & 0 & 0 & * & * \\ 0 & 1 & 0 & * & * \\ 0 & 0 & 1 & * & * \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 \end{bmatrix} \quad \text{or} \quad \begin{bmatrix} 1 & 0 & 0 & * & * \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \end{bmatrix} + \varepsilon_1 \begin{bmatrix} * & * & * \\ 0 & * & 0 \\ 0 & 0 & * \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} + \varepsilon_2 \begin{bmatrix} * & * & * \\ 0 & * & 0 \\ 0 & 0 & * \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

6.5. **Cycle of tree lines.** According to Section 3, the original matrix problem $MP_E$ with two blocks on each component is

Matrices $\mu_1(0), \mu_2(0)$ and $\mu_3(0)$ can be reduced to the identity form. The matrix $\mu_3(\infty)$ can be reduced to the form (11). For the morphisms we have

$$f_1 = F_1(0), \ f_2 = F_2(0), \ f_3 = F_3(0) \ \text{and} \ F_3(\infty)\mu_3(\infty) = \mu_3(\infty)f_1.$$

Then the matrix $f_3$ has a special block-triangular structure. In other words, the matrix $\mu_2(\infty)$ is subdivided into four column-blocks: a column can be added to any
other column from a block on the left and it cannot be added to a column from another block on the right. Thus $\mu_2(\infty)$ can be reduced to the form

$$\mu_2(\infty) = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 5 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 3 \\
0 & 0 & 0 & 0 & 0 & 1 & 1 & 7 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 2 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 6 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 4 \\
0 & 0 & 0 & 0 & 0 & 1 & 1 & 8 \\
\end{pmatrix}$$

Reduced matrix problem. The remaining nonreduced matrix is $M := \mu_1(\infty)$. For it we obtain the problem $M \mapsto SM(S')^{-1}$, where the transformations are $(S, S') = (F_1(\infty), f_3)$. Equations (15) together with $F_3(\infty)\mu_2(\infty) = \mu_2(\infty)f_3$ imply the triangular forms for the matrices $F_k(0), F_k(\infty)$ and $f_k$ (for $k = 1, 2, 3$); in particular:

$$(S, S') = \begin{pmatrix}
w_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
* & w_2 & 0 & 0 & 0 & 0 & 0 & 0 \\
* & * & w_3 & 0 & 0 & 0 & 0 & 0 \\
* & * & * & w_4 & 0 & 0 & 0 & 0 \\
* & * & * & * & w_5 & 0 & 0 & 0 \\
* & * & * & * & * & w_6 & 0 & 0 \\
* & * & * & * & * & * & w_7 & 0 \\
* & * & * & * & * & * & * & w_8 \\
\end{pmatrix}$$

The stars $*$ denote arbitrary blocks and $w_i$ for $i = 1, \ldots, 8$ are the common diagonal blocks. The transformations of row and column -blocks of $M$ are clear: a row can be added to any other one from a block below and it can’t be added to a row from a block above it. and a column can be added to any other column from a block on the left and it can not be added to a column from a block on the right.

Nontrivial morphisms. Analogously as in the case of a cycle of two lines there are some pairs $(ij) \in I \times I$ such that if $s_i \cdot s_j > 0$ then there exists a nontrivial endomorphism. Such blocks are called mutually excluding and denoted by $i \cap j$.

- If the matrices $F_3(\infty)$ and $F_1(0)$ contain at least one of the following entries: (71), (81), (72) or (82) then there is a nontrivial endomorphism. In our short notations we have an intersection 1, 2 \cap 7, 8. In the same way we have 1, 5 \cap 4, 8. The nontrivial morphisms are induced by the matrices $F_3(0)$ and $F_2(\infty)$. 
The blocks 1 and 6 are mutually excluding; the endomorphism is induced by the entry (61) of the matrices $F_3(0)$, $F_3(\infty)$ and $F_2(\infty)$. Similarly, there is an endomorphism for the pair (38) induced by the matrices $F_1(0)$, $F_3(\infty)$ and $F_3(0)$.

All the mutually excluding blocks can be indicated on the intersection diagram:

\[
\begin{array}{ccc}
2 & 3 & 1 \\
\cap & \cap & 5 \\
7 & 8 & 6 & 4
\end{array}
\]

The diagram reads as follows: a matrix $M$ is a brick if it contains no pair of blocks $(ij)$ such that $i$ and $j$ in the diagram are separated by $\cap$ and either in the same column or one of them is 1 or 8.

In the following table we present the maximal tuples of blocks $I = (i_1, i_2, i_3, i_4)$ for $M$ being a brick, express the dimension vector $s = (s_{i_1}, s_{i_2}, s_{i_3}, s_{i_4}) \in \mathbb{N}^4$ in terms of rank and multidegree and moreover, answer the question when such tuple of blocks appears and specialize the matrix problems in each case.

| condition | set $I$ | dimension vector $s$ | state |
|-----------|---------|----------------------|-------|
| 1. $r \geq \bar{d}$ | $(1, 2, 3, 5)$ | $(r - \bar{d}, d_1, d_2, \bar{d}_1)$ | $A^+$ |
| $d > r$ | $(4, 6, 7, 8)$ | $(r - d, r - d_3, r - d_2, \bar{d} - r)$ | $A^-$ |
| $d > (d_2 + d_3), (\bar{d}_1 + \bar{d}_3)$ | $(2, 3, 5, 6)$ | $(r - (d_2 + d_3), d_3, r - (d_2 + d_3), \bar{d} - r)$ | $A^-$ |
| $(\bar{d}_2 + d_3), (\bar{d}_1 + d_3) > r$ | $(3, 4, 6, 7)$ | $(2r - d, (\bar{d}_2 + d_3) - r, r - d_3, (\bar{d}_1 + d_3) - r)$ | $A^+$ |
| $(\bar{d}_2 + d_3) \geq r \geq (d_2 + d_3)$ | $(2, 3, 4, 6)$ | $(r - (\bar{d}_1 + d_3), r - d_2, (d_2 + d_3) - r, d_1)$ | $C$ |
| $(\bar{d}_1 + d_3) \geq r \geq (d_2 + d_3)$ | $(3, 5, 6, 7)$ | $(r - \bar{d}_1, r - (d_2 + d_3), d_2, (\bar{d}_1 + d_3) - r)$ | $C$ |

Table 3.

The configurations $A^+, A^-$ and $C$ on the set of blocks $I = \{i_1, i_2, i_3, i_4\}$ encode matrix problems $M \mapsto SM(S')^{-1}$, where $S$ and $S'$ are block-triangular and the matrix $M$ is defined as follows:

\[
A^+ = \begin{pmatrix}
a_{i_1} & * & * & * \\
* & * & a_{i_2} & i_2 \\
* & a_{i_3} & * & * \\
* & * & a_{i_4} & * \\
i_1 & i_2 & i_3 & i_4
\end{pmatrix} \quad A^- = \begin{pmatrix}
a_{i_1} & * & * & * \\
* & a_{i_2} & * & * \\
a_{i_3} & * & * & * \\
* & a_{i_4} & * & * \\
i_1 & i_2 & i_3 & i_4
\end{pmatrix} \quad C = \begin{pmatrix}
a_{i_1} & * & * & * \\
d_{i_2} & * & * & * \\
* & a_{i_3} & * & * \\
* & * & a_{i_4} & * \\
i_2 & i_1 & i_4 & i_3
\end{pmatrix}.
\]

6.6. Thee concurrent lines in a plane. Let $E$ be the Kodaira fiber IV and $MP_E$ the matrix problem formulated in Subsection 4 with two blocks for each component. In this section we reduce it to a partial canonical form. At first we reduce matrices $\mu_1(0)$ and $\mu_2(0)$ as in the case of a tacnode curve. Then the transformations satisfy equations (14). Let us find a canonical form of $\mu_3(0)$ with respect to the transformations $\mu_3(0) \mapsto F_3(0)\mu_3(0)f(0)^{-1}$. The splitting of $F_3(0)$ and $f(0)$ into blocks induces the same column block structure for $\mu_3(0)$ as in the case of a cycle of three
lines. However, on the contrary to that case, there is no addition from the third column-block to the second one. Thus proceeding as before instead of the form \( \mathbf{16} \) we obtain only the following:

\[
\begin{array}{cccccccc}
1 & 2 & 5 & 6 & 3 & 4 & 7 & 8 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & * & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
\end{array}
\]

\( \mu_3(0) = \)

It turns out that the remaining block * can be reduced to the form \( (0 \ 0) \) as well. That implies subdivisions for the reduced blocks marked by 3 and 6: and change of notations is required: \( 3 \mapsto (3, 0) \) and \( 6 \mapsto (0, 6) \).

The equation \( F_3(0)\mu_3(0) = \mu_3(0)f(0) \) implies that the matrix \( F_1(0) \) preserving \( \mu_3(0) \) is as follows:

\[
\begin{array}{cccccccc}
1 & 2 & 3 & 0 & 4 & 5 & 0 & 6 \\
w_0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
* & w_1 & 0 & 0 & 0 & 0 & 0 & 0 \\
* & 0 & w_2 & 0 & 0 & 0 & 0 & 0 \\
* & x & * & z & 0 & 0 & 0 & 0 \\
* & * & * & w_4 & 0 & 0 & 0 & 0 \\
* & 0 & 0 & 0 & w_5 & 0 & 0 & 0 \\
* & x & 0 & 0 & 0 & z & 0 & 0 \\
* & * & 0 & 0 & 0 & * & w_7 & 0 \\
* & 0 & * & y & 0 & * & y & 0 \\
* & * & * & * & * & * & * & w_9 \\
\end{array}
\]

As usually the stars * denote different blocks appearing only one time and \( x, y \) and \( z \) are some blocks appearing twice. By proper \( f_x(0) \) and \( f_y(0) \) the matrices \( \mu_{\varepsilon_2}(0) \) and \( \mu_{\varepsilon_3}(0) \) can be reduced to zero. Taking into account equations \( F_k(0)\mu_k(0) = \mu_k(0)f(0) \) for \( k = 2, 3 \) we obtain that there are nonzero matrices \( f_x(0) \) and \( f_y(0) \) leaving the matrices \( \mu_{\varepsilon_2}(0) \) and \( \mu_{\varepsilon_3}(0) \) in the zero form. This consideration becomes important below, where we are looking for endomorphisms.

**Reduced matrix problem.** As usually take \( M := \mu_{\varepsilon_1}(0) \) and transformations \( M \mapsto SMS^{-1} \) modulo zero blocks of \( M \), where \( S := F_1(0) \). By proper \( F_1(0), f_x(0) \)
and $f_y(0)$ it can be reduced to the form

$$M = \begin{pmatrix}
1 & 2 & 3 & 0 & 4 & 5 & 0 & 6 & 7 & 8 \\
1 & * & * & * & * & * & * & * & * & * \\
2 & 0 & * & 0 & 0_y & * & 0 & 0_y & * & 0 \\
3 & 0 & 0 & * & * & 0 & 0 & 0 & * & * \\
4 & 0 & 0 & 0 & 0_z & * & 0 & 0 & 0_x & * \\
5 & 0 & 0 & 0 & 0 & 0 & * & 0 & 0 & 0 \\
6 & 0 & 0 & 0 & 0 & 0 & 0 & * & 0 & * \\
7 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * \\
8 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * \\
\end{pmatrix}$$

The blocks denoted by $0_x$ (respectively $0_y$ or $0_z$) are the so called adjoint blocks, which means that there is a unique block $x$ (respectively $y$ or $z$) operating on both of them, and thus only one block from an adjoint pair can be reduced to zero.

**Nontrivial morphisms.** Let us analyze matrices $\frac{dF_k}{dz_0}(0)$, $f_x(0)$ and $f_y(0)$ looking for an endomorphism. As in the case of a tacnode curve there are places $(ij)$, where zero can be obtained in two or more different ways. That is if $s_i \cdot s_j > 0$ then there exists a nonscalar endomorphism. The diagram of mutually excluding blocks is almost the same as diagram (17) for the cycle of three lines but with one extra relation (now blocks 3 and 6 are mutually excluding):

(19)

In Table 4 we present the maximal tuples $I = \{i_1, i_2, i_3, i_4\}$, interpret the dimension vector $s$ in terms of rank and multidegree and specialize matrices that we get in each case.

By $A^\sigma$ and $B^\sigma(j)$ we denote the matrix problems given by the following coincidence matrices $M$:

(20)

As usually, the matrix problems are $M \mapsto SMS^{-1}$ modulo empty spaces and the transformation $S$ has the form transposed to $M$. 
In this section we use the technique of boxes and follow the notations of [BD09]. From now on let $\mathfrak{A}$ be a Roiter box and $(Q, \partial)$ its differential biquiver, where $Q = (I, Q_0, Q_1)$ with the set of vertices $I$ and the sets of solid and dotted arrows respectively $Q_0$ and $Q_1$. Let $\mathfrak{A} \text{-mod}$ be the category of finite dimensional $\mathfrak{A}$-modules and $\text{Br}_{\mathfrak{A}}$ its full subcategory of bricks. For details concerning boxes we also refer to [Dro01] and [Bod07].

Summarizing previous sections we conclude that our approach provides a full and dense functor $\text{VB}_E \xrightarrow{\sim} \text{Tr}_E \xrightarrow{} \text{MP}_E$ and the primary reduction is an equivalence of categories $\text{MP}_E(\mathfrak{r}) \xrightarrow{\sim} \text{Br}_{\mathfrak{Q}}(\mathfrak{s})$, for some special box $\mathfrak{A}$ and dimension vector $\mathfrak{s}$. The composition of these functors yields an equivalence $\text{VB}_E^*(r, \mathfrak{d}) \xrightarrow{\sim} \text{Br}_{\mathfrak{A}}(\mathfrak{s})$, where both the box $\mathfrak{A}$ and the tuple $\mathfrak{s}$ are uniquely defined by the curve $E$, the rank $r$ and the multidegree $\mathfrak{d}$.

In most situations it is useful to present a representation $M$ as a block-matrix with the block $M(x)$ on the place $(ij)$ for $x \in Q_0(j,i)$. With a little abuse of notations we write $M$ in a form of a table with $x$ on the $ij$-entry instead of $M(x)$. In accordance with notations from Section 3 “1” and “0” denote an identity block and a zero block. The morphisms $S$ are given in a similar way.

**Class of BC-boxes.** A box $\mathfrak{A}$ with the differential biquiver $(Q, \partial)$ is of BC-type if its solid arrows form an $I \times I$ matrix. There are two total orders on the set $I$: a row

| condition | set $I$ | dimension vector $\mathfrak{s}$ | state |
|-----------|---------|---------------------------------|-------|
| 1. $r \geq \bar{d}$ | (1, 2, 3, 5) | $(r - \bar{d}, \bar{d}_1, \bar{d}_2, \bar{d}_3)$ | $A^+$ |
| 1’. $\bar{d} > 2r$ | (4, 6, 7, 8) | $(r - \bar{d}_1, r - \bar{d}_2, r - \bar{d}_3, \bar{d} - 2r)$ | $A^-$ |
| 2. $\bar{d} > r > \bar{d}_i + \bar{d}_j$ for all $i, j \in \{1, 2, 3\}$ | (2, 3, 5, 0) | $(r - (\bar{d}_1 + \bar{d}_2), r - (\bar{d}_1 + \bar{d}_3), r - (\bar{d}_2 + \bar{d}_3), \bar{d} - r)$ | $A^-$ |
| 2’. $\bar{d}_i + \bar{d}_j > r$ and $2r > \bar{d}$ for all $i, j \in \{1, 2, 3\}$ | (0, 4, 6, 7) | $(2r - \bar{d}, (\bar{d}_2 + \bar{d}_3) - r, (\bar{d}_1 + \bar{d}_3) - r, (\bar{d}_1 + \bar{d}_2) - r)$ | $A^+$ |
| 3. $(d_2 + d_3) > r$ and $r > (d_1 + d_2), (d_1 + d_3)$ | (2, 3, 0, 4) | $(r - (\bar{d}_1 + \bar{d}_2), r - (\bar{d}_1 + \bar{d}_3), \bar{d}_1, (\bar{d}_2 + \bar{d}_3) - r)$ | $B^-(0)$ |
| 3’. $(d_1 + d_2), (d_1 + d_3) > r$ | (5, 0, 6, 7) | $(r - (\bar{d}_2 + \bar{d}_3), r - \bar{d}_1, (\bar{d}_1 + \bar{d}_3) - r, (\bar{d}_1 + \bar{d}_2) - r)$ | $B^+(0)$ |
| 4. $(d_1 + d_3), (d_2 + d_3) > r$ and $r > (d_1 + d_2), (d_1 + d_3)$ | (0, 2, 4, 6) | $(r - (\bar{d}_1 + \bar{d}_2), r - \bar{d}_3, (\bar{d}_2 + \bar{d}_3) - r, (\bar{d}_1 + \bar{d}_3) - r)$ | $B^+(0)$ |
| 4’. $(d_1 + d_2) > r$ and $r > (d_1 + d_3), (d_2 + d_3)$ | (3, 5, 0, 7) | $(r - (\bar{d}_1 + \bar{d}_3), r - (\bar{d}_2 + \bar{d}_3), \bar{d}_3, (\bar{d}_1 + \bar{d}_2) - r)$ | $B^-(0)$ |
| 5. $(d_1 + d_3) > r$ and $r > (d_1 + d_2), (d_2 + d_3)$ | (2, 5, 0, 6) | $(r - (\bar{d}_1 + \bar{d}_2), r - (\bar{d}_2 + \bar{d}_3), \bar{d}_2, (\bar{d}_1 + \bar{d}_3) - r)$ | $B^- (0)$ |
| 5’. $(d_1 + d_2), (d_2 + d_3) > r$ and $r > (d_1 + d_3)$ | (2, 0, 4, 7) | $(r - (\bar{d}_1 + \bar{d}_3), r - \bar{d}_2, (\bar{d}_2 + \bar{d}_3) - r, (\bar{d}_1 + \bar{d}_2) - r)$ | $B^+(0)$ |

Table 4.
order denoted by \(<_r\) and a column order denoted by \(<_c\). The set of dotted arrows \(Q_1\) consists of two subsets: \(\{u \in Q_1(k, j) | j >_c k\}\) and \(\{v \in Q_1(i, l) | l >_c i\}\). For each \(x \in Q_0(i, j)\), the differential is
\[
\partial(x) = \sum_{l <_c i} x' v - \sum_{j <_c k} u x'',
\]
where \(x' \in Q_0(l, j)\) and \(x'' \in Q_0(i, k)\) are uniquely defined as the entries \((jl)\) and \((ki)\) of the matrix \(I \times I\). Such boxes can be presented via matrices \(M\) and \((S, S')\) and matrix multiplications: \(M \mapsto SM(S')^{-1}\), where

\[
M = \begin{pmatrix}
c_1 & \cdots & c_n \\
x_{r_1 c_1} & \cdots & x_{r_1 c_n} \\
\vdots & \ddots & \vdots \\
x_{r_n c_1} & \cdots & x_{r_n c_n}
\end{pmatrix}
\]

\[(S, S') = \begin{pmatrix}
w_{r_1} & 0 & 0 \\
\vdots & \ddots & \vdots \\
w_{r_n} & 0 & 0
\end{pmatrix}
\]

and \((r_1 \ldots r_n)\) and \((c_1, \ldots, c_n)\) are orders \(<_r\) and \(<_c\) on \(I\), i.e. \(r_1 <_r r_2 <_r \cdots <_r r_n\) and \(c_1 <_c c_2 <_c \cdots <_c c_n\). The reduced matrix problem for a nodal curve from Subsection 6.4 as well as all the problems \(A^+, A^-, C\) from Subsections 6.3 and 6.5 are of BC-type.

**Class of BT-boxes.** A box \(\mathfrak{A}\) with the differential biquiver \((Q, \partial)\) is of BT-type if there exists a set of distinguished loops: \(\mathfrak{a} := \{a_i \in Q_0(i, i) | i \in I\}\), an injective map: \(v : Q_0 \setminus \mathfrak{a} \mapsto Q_1\), mapping a solid arrow \(a : i \to j\) to an opposite directed dotted arrow \(v_a := v(a) : j \to i\), and for each distinguished loop \(a_i \in \mathfrak{a}\) we have
\[
(21) \quad \partial a_i = \sum_{c <_c i} c \cdot v_c - \sum_{d > d} v_d \cdot d.
\]

For a box \(\mathfrak{A}\) of BT-type its biquiver \(Q\) can be encoded as follows: a vertex \(i \in I\) is denoted by a bullet \(\bullet\); on the set of vertices we draw the graph with arrows \(Q_0 \setminus \mathfrak{a}\). Such system of notations becomes quite useful since in most of our cases the way to recover the differential is clear.

The BT-box \(\mathfrak{A}\) obtained Subsection 6.2 for a cuspidal cubic curve is \(1 \bullet \longrightarrow 2 \bullet\). The problems on three vertices \(A^+\) and \(A^-\) from Subsection 6.3 and the problems on four vertices: \(A^+, A^-, B^+(j)\) and \(B^-(i)\) from Subsection 6.6 are also of BT-type:

**Remark 7.1.** Described BT-boxes and the BT-boxes which appear in the following sections determine partially ordered sets \((I, \prec)\), by the rule \(i \prec j\) if there exists \(x \in Q_0(j, i)\). In most of our cases a poset determine the box, however in general,
it does not provide enough information to recover the differential. On the other hand, a pair of linear orders \(<_r\) and \(<_c\) determine a partial order \(<\) by the rule \(i < j\) if \(i <_r j\) and \(i <_c j\). Posets obtained in such a way relay BC and BT-boxes. Moreover, for the BT-box they determine the canonical minimal edge \((ij)\), where \(i\) is the minimal with respect to the total order \(<_r\) and \(j\) is the maximal with respect to \(<_c\). Thus having a fixed dimension vector \(s\), not only for a BC-box but also for the corresponding BT-box we have the canonical course of reduction.

**Bricks and small reduction.** Boxes of BC and BT-types possess a common property. The following proposition allow us to replace the usual matrix reduction by the small one.

**Proposition 7.2.** Let \(\mathfrak{a}\) be a box of BC or BT type, \(b : i \to j\) its minimal edge and \(M\) a brick. Then \(M(b)\) has maximal rank.

**Proof.** Let \(\mathfrak{a}\) be a box of BC-type. Since \(\mathfrak{a}\) is an example of bunches of chains, we can assume that \(M\) is reduced to its canonical form. Also assume that \(M(b) = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}\). Let rows and columns of \(M\) be ordered \(1, \ldots, R\). For a place \(t \in \{1, \ldots, R\}\) by \(r(t)\) and \(c(t)\) we denote the row-block and the column-block containing \(t\). For example, since rows and columns are ordered, we have \(r(1) = j\) and \(c(R) = i\). If \(M\) is invertible then there exist places \(m\) and \(n\) such that \(M_{1m} = M_{nR} = 1\) and all the other entries in the first row and the last (\(R\)-th) column are zero. A nonscalar endomorphism \((S, S')\) of \(M\) can be constructed by taking nonzero \(S_{n1} = -S'_{Rm}\), diagonal entries to be, for example, 1 and all the other non-diagonal entries to be zero. Since \(c(m) < c i\) and \(r(n) > r j\) the block \(S_{r(n)r(1)}\) containing the entry \(S_{n1}\) and the block \(S'_{c(R)c(m)}\) containing the entry \(S'_{Rm}\) are nonempty. If \(M\) is degenerated the proof is even simpler: if the first row (or the last column) is zero we add it to any other one and obtain a nonscalar endomorphism.

If \(\mathfrak{a}\) is a box of BT-type then after a step of minimal edge reduction there is a dotted arrow which is not involved in any differential and hence there is a nonscalar endomorphism (for details see [BD09, Lemma 4.6]).

7.1. **Small reduction automaton.** Recall that an automaton is an oriented graph on the set of vertices called states, whose arrows are transitions from a state to a state. In our case the states are the matrix problems and the transitions encode either admissible or canonical steps of reduction.

**Definition 7.3.** A small-reduction automaton is an oriented graph \(\Gamma\) on the set of internal states, where

- \(\Gamma\) is a finite set of boxes, whose differential biqivers have the same finite set of vertices \(I\).
- The set of transitions is \(I \times I\).
- For a minimal solid arrow either \(j \to i\) or \(i \to j\) the transition \((ij) : \gamma \to \gamma'\) acts on the space of sizes \(N^{[I]}\) as follows: \(s \mapsto s'\), where \(s'_k = s_k\) for \(k \neq i\) and \(s_i \mapsto s_i - s_j\). If an arrow \(l \to k\) is not minimal then the transitions \((lk), (kl) : \gamma \to \gamma\) do not act at all and we omit them.
A sequence $p := (i_1,j_1)(i_2,j_2)\ldots(i_k,j_k)$ of transitions is called a path if the target of $(i_k,j_k)$ coincides with the source of $(i_{k+1},j_{k+1})$. A path operates on the set of sizes: $p : \mathbf{s} \mapsto \mathbf{s}'$, where $\mathbf{s} \geq \mathbf{s}'$ i.e. $s_i \geq s_i'$ for all $i \in I$. Two paths $p_1$ and $p_2$ with a common source and a common target are called equivalent if for any tuple of sizes $\mathbf{s} \in \mathbb{N}^I$ we have $p_1(\mathbf{s}) = p_2(\mathbf{s})$. The semigroup of paths modulo the equivalence relation is called the semigroup of the automaton and is denoted by $\Omega$.

**Principal states.** Let $\Gamma$ be an automaton of small reduction starting with one of the boxes form Tables 2–4. A state $\gamma \in \Gamma$ is called principal if it can be interpreted in terms of vector bundles $\text{Br}_\gamma(\mathbf{s}) \cong \text{VB}_E^r(\mathbf{r}, \mathbf{d})$ i.e if it can be found in the corresponding table. (Note that an interpretation of a state is not unique in general). In the following sections our main goal is to show that the set $\text{Br}_\gamma(\mathbf{s}) \cong \text{VB}_E^r(\mathbf{r}, \mathbf{d})$ is nonempty if and only if $\gcd(\mathbf{r}, \mathbf{d}) = 1$. Then we obtain that for a rank $r$ and a multidegree $\mathbf{d}$ such that $\gcd(r,d) = 1$ there exists a path $p$ connecting principal states on the automaton such that

$$
\begin{align*}
\text{VB}_E^r(\mathbf{r}, \mathbf{d}) \cong \text{Pic}^{(0,\ldots,0)}(E) \\
\text{Br}_\mathfrak{A}(\mathbf{s}) \xrightarrow{p} \text{Br}_\mathfrak{A}(1,0,\ldots,0).
\end{align*}
$$

In the following sections we construct the small reduction automaton for each plane degeneration of an elliptic curve. Then a canonical form of a simple vector bundle can be constructed as follows.

**7.2. Algorithm.** Let $E$ be a plane degeneration of an elliptic curve with $N$ components, $(\mathbf{r}, \mathbf{d}) \in \mathbb{N} \times \mathbb{Z}^N$ be a tuple of integers, such that $\gcd(r,d) = 1$; where $d = \sum_{k=1}^N d_k$ and let $\lambda \in \mathbb{k}$ be a continuous parameter.

1. By Euclidean algorithm we find integers $c_k, \bar{d}_k$ such that $d_k = n_k r + \bar{d}_k$ for $k = 1, \ldots, N$, and recover the normalization vector bundle $\mathbb{F}$:

$$
F|_{L_k} = (\mathcal{O}_{L_k}(n_k))^{|r-\bar{d}_k|} \oplus (\mathcal{O}_{L_k}(n_k + 1))^{\bar{d}_k}.
$$

2. By the primary reduction we obtain the matrix problem $\text{Br}_\mathfrak{A}$ and the tuple of integers $\mathbf{s} \in \mathbb{N}^{N+1}$.

3. Use the matrix problem $\text{Br}_\mathfrak{A}(\mathbf{s})$ as the input data for the corresponding small-reduction automaton. Choose a path $p$ on it such that $p(\mathbf{s}) = (1,0,\ldots,0)$.

4. Starting with the one-dimensional matrix $[\lambda] \in \text{Br}_{\mathfrak{A}[\lambda]}(1)$ reverse course of reduction along the path $p$. This way step-by-step, we recover the canonical form $B(\lambda) = p^{-1}(\lambda) \in \text{Br}_\mathfrak{A}(\mathbf{s}) \cong \text{VB}_E^r(\mathbf{r}, \mathbf{d})$.

**8. Small reduction for nodal and cuspidal cubic curves**

The categories obtained in Subsections 6.1 and 6.2 can be interpreted as the categories $\mathfrak{A}-\text{mod}(s_1,s_2)$, where $\mathfrak{A}$ are boxes of either $\text{BC}$ and $\text{BT}$-types. We present $\mathfrak{A}$ for a nodal curve as a differential biquiver, despite the agreement to present
BC-boxes by tables, in order to illustrate the language of boxes:

\[ \begin{array}{ccc}
\text{1} & \text{2} & \text{3} \\
a_1 & * & * \\
* & a_2 & * \\
* & * & a_3 \\
\end{array} \quad \begin{array}{ccc}
\text{1} & \text{2} & \text{3} \\
b & * & * \\
* & v & * \\
* & * & u \\
\end{array} \]

and

\[ \begin{array}{ccc}
\text{1} & \text{2} & \text{3} \\
a_1 & * & * \\
* & a_2 & * \\
* & * & a_3 \\
\end{array} \quad \begin{array}{ccc}
\text{1} & \text{2} & \text{3} \\
b & * & * \\
* & v & * \\
* & * & u \\
\end{array} \]

In both cases the steps of small reduction are \( A \xrightarrow{\text{(12)}} (21) \overset{\text{(21)}}{\longrightarrow} A \). In other words, both problems are self-reproducing, and the small-reduction automaton is

(22) \( (21) \overset{\text{(21)}}{\longrightarrow} (12) \).

The transitions act on sizes as (21) : \( (s_1, s_2) \mapsto (s_1, s_2 - s_1) \) and (12) : \( (s_1, s_2) \mapsto (s_1 - s_2, s_2) \). In terms or rank and degree we get

(21) : \( \text{VB}_E^s(r, \bar{d}) \rightarrow \text{VB}_E^s(r - \bar{d}, 2d - r) \) and (12) : \( \text{VB}_E^s(r, \bar{d}) \rightarrow \text{VB}_E^s(r - \bar{d}, \bar{d}) \).

That implies the statement of Theorem 1.2 for irreducible cubic curves.

**Remark 8.1.** The semigroup of paths \( \Omega = \langle (21), (12) \rangle \) generates the group SL(2, Z).

On the other hand it is interesting to note that the group of autoequivalences \( \text{Aut} (\mathcal{D}^b(\text{Coh}_E)) = \langle T_\sigma, T_{\chi(p_0)} \rangle \) also acts as SL(2, Z) on the \( K \)-group, or what is equivalent, on rank and degree. By Theorem 4.1 of [BK06] autoequivalences \( T_\sigma \) and \( T_{\chi(p_0)} \) send stable sheaves to stable sheaves. Moreover, a continuous parameter \( \lambda \) can be considered as a regular point on the curve \( E \), hence it is preserved under the action of \( T_\sigma \) and \( T_{\chi(p_0)} \). Therefore, for singular Weierstraß curves the action on discrete parameters of the matrix reduction coincides with the action of Fourier-Mukai transforms, namely: (21) acts as \( T_\sigma \) and (12) acts as \( (T_{\chi(p_0)})^{-1} \).

9. SMALL REDUCTION FOR A KODAIRA FIBERS I_2 AND III.

In Subsections 6.3 and 6.4 we obtained an equivalence \( \text{MP}^s(r, s) \xrightarrow{\text{br}} \text{Br}_3(s) \), where the box \( A \) is the configuration \( A^\sigma \), of BC or BT-type, \( \sigma \in \{+, -\} \) depending on whether \( r > d \) or \( r < d \). Applying small reduction to the box \( A^\sigma \) we obtain one other type of boxes on 3 blocks, called \( B \) configuration defined by the standard numeration of blocks (1, 2, 3). In the BC-case we get:

\[
B = \begin{pmatrix}
1 & 2 & 3 \\
\ast & \ast & \ast \\
\ast & \ast & \ast \\
\end{pmatrix}
\quad (S, S') = \begin{pmatrix}
1 & 2 & 3 \\
1 & w_1 & 0 \\
2 & u_3 & w_2 \\
3 & u_2 & u_1 \\
\end{pmatrix}
\begin{pmatrix}
1 & 2 & 3 \\
w_1 & 0 & 0 \\
v_3 & w_2 & 0 \\
v_2 & v_1 & w_3 \\
\end{pmatrix}.
\]
As was mentioned in Remark 7.1 column and row-orders define a poset. Configurations \(A^+, A^-\) and \(B\) determine respectively the posets

\[
\begin{array}{c}
\text{A}^+ \quad \begin{array}{c}
1 \\
2 \\
3
\end{array} \quad \begin{array}{c}
\uparrow \\
\downarrow
\end{array} \\
\end{array} \quad \begin{array}{c}
\text{A}^- \quad \begin{array}{c}
1 \\
2 \\
3
\end{array} \quad \begin{array}{c}
\uparrow \\
\downarrow
\end{array} \\
\end{array} \quad \begin{array}{c}
\text{B} \quad \begin{array}{c}
1 \\
2 \\
3
\end{array} \quad \begin{array}{c}
\uparrow \\
\downarrow
\end{array}
\end{array}
\]

To a poset one can associate a \(\mathcal{B}T\)-differential biquiver. For example, for \(A^-\) we have the following \(\mathcal{B}T\)-differential biquiver:

\[
(Q, \partial) = \begin{array}{c}
\begin{array}{c}
1 \\
\downarrow
\end{array} \\
\begin{array}{c}
2 \\
\downarrow
\end{array} \\
\begin{array}{c}
3 \\
\downarrow
\end{array}
\end{array} \quad \begin{array}{c}
a_1 \\
\uparrow
\end{array} \quad \begin{array}{c}
av_b \\
\downarrow
\end{array} \quad \begin{array}{c}
av_c \\
\uparrow
\end{array} \quad \begin{array}{c}
av_a \\
\downarrow
\end{array} \quad \begin{array}{c}
av_2 \\
\uparrow
\end{array} \quad \begin{array}{c}
v_a \\
\downarrow
\end{array} \quad \begin{array}{c}
a_2 \\
\uparrow
\end{array}
\end{array} \quad \begin{array}{c}
\partial(b) = 0, \\
\partial(a_1) = bv_b, \\
\partial(a_2) = cv_c, \\
\partial(a_3) = -v_bb - v_cc.
\end{array}
\]

and for \(B\) we have the following \(\mathcal{B}T\)-differential biquiver:

\[
(Q, \partial) = \begin{array}{c}
\begin{array}{c}
1 \\
\downarrow
\end{array} \\
\begin{array}{c}
2 \\
\downarrow
\end{array} \\
\begin{array}{c}
3 \\
\downarrow
\end{array}
\end{array} \quad \begin{array}{c}
a_1 \\
\uparrow
\end{array} \quad \begin{array}{c}
av_a \\
\downarrow
\end{array} \quad \begin{array}{c}
av_b \\
\downarrow
\end{array} \quad \begin{array}{c}
av_c \\
\uparrow
\end{array} \quad \begin{array}{c}
av_2 \\
\uparrow
\end{array} \quad \begin{array}{c}
v_a \\
\downarrow
\end{array} \quad \begin{array}{c}
a_2 \\
\uparrow
\end{array}
\end{array} \quad \begin{array}{c}
\partial(b) = 0, \\
\partial(a) = bv_c, \partial(c) = -v_bb, \\
\partial(a_1) = bv_b + av_a, \\
\partial(a_2) = cv_c - v_a, \\
\partial(a_3) = -v_bb - v_cc.
\end{array}
\]

In Subsection 6.4 we obtained an equivalence \(\text{MP}_s^{\mathfrak{A}}(r, d_1, d_2) \xrightarrow{\sim} \text{Br}_\mathfrak{A}(s_1, s_2, s_3)\), where \(\mathfrak{A}\) was a \(\mathcal{B}T\)-box of type either \(A^+\) or \(A^-\). Hence, the small reduction automaton for a cycle of two lines and the canonical one for a tacnode curve is

\[
(21) \quad (12) \quad (13) \quad (31) \quad (32) \quad (23)
\]

We claim that the reduction can terminate only at the states \(A^+\) and \(A^-\), which are principal. Indeed, assume that we have the box \(B\) with sizes \(s_1 = s_3\). Then the matrix can be reduced to the canonical form:

\[
\begin{pmatrix}
0 & 0 & 1 \\
0 & J_1 & 0 \\
J_2 & 0 & 0
\end{pmatrix}
\]

where \(J_1\) and \(J_2\) are Jordan cells with nonzero eigenvalues. It is quite obvious that this matrix is decomposable. Analogously in the case of Kodaira fiber III: the reduction can terminate only at a state of type \(A\). Indeed, if \(s_1 = s_3\) then the configuration \(B\) produces a splitting; and for \(A^+\) we get the problem \(\text{Br}_\mathfrak{A}(s_1, s_2)\),
where $A$ is the box as for a cuspidal cubic curve with sizes $(s_1, s_2, s_3) \mapsto (s_1, s_2)$:

By gluing paths we can construct the automaton on principal states:

For a principal configuration $A^\sigma$ we introduce its new discrete parameters $(\alpha, \beta) : (A^+, A^-)$ let $(A^+, A^-)$ be a path on the principal automaton (26) taking $s \mapsto s'$ and respectively $(\alpha, \beta) \mapsto (\alpha', \beta')$. Then $\gcd(\alpha, \beta) = \gcd(\alpha', \beta')$.

**Lemma 9.1.** Let $p : A^\sigma \to A'^\sigma$ be a path on the principal automaton (26) taking $s \mapsto s'$ and respectively $(\alpha, \beta) \mapsto (\alpha', \beta')$. Then $\gcd(\alpha, \beta) = \gcd(\alpha', \beta')$.

**Proof.** It is sufficient to prove the statement on the following transitions: (23), (32)(31) : $A^- \to A^-$ and (13)(32) : $A^- \to A^+$. Indeed, we have

$(23) : (s_1, s_2, s_3) \mapsto (s_1, s_2 - s_3, s_3)$ and hence $(\alpha, \beta) \mapsto (\alpha - \beta, \beta)$;

$(32)(31) : (s_1, s_2, s_3) \mapsto (s_1, s_2, s_3 - (s_1 + s_2))$ and $(\alpha, \beta) \mapsto (\alpha, \beta - \alpha)$;

$(13)(32) : (s_1, s_2, s_3) \mapsto (s_1 + s_2 - s_3, s_2, s_3 - s_2)$ and $(\alpha, \beta) \mapsto (\alpha - \beta, \beta)$.

Let $\mathcal{V}B_E^*(r, d) \xrightarrow{\cong} \mathcal{V}B_E^*(r', d')$ be a functorial bijection obtained by the course of small reductions along the path $p$. Replacing the dimension vector $s$ by the tuple $(r, d)$ using Table 2 we obtain $(\alpha, \beta) = (r - d \mod r, d \mod r)$. If $\gcd(r, d) = 1$, at the end of reduction we get $\mathcal{V}B_E^*(r, d) \xrightarrow{\cong} \text{Pic}^{[0,0]}(E)$, and there is no bricks otherwise. Hence, Lemma 9.1 implies Theorem 1.2 for curves I$_2$ and III.

### 10. Small reduction for Kodaira fibers I$_3$ and IV.

In Subsection 6.5 we obtained equivalences $\mathcal{M}P_1^*(r, d) \xrightarrow{\cong} \text{Br}_3(s)$, $s \in \mathbb{N}^4$, where $A$ is a BC-box of type $A^+, A^-$ or $C$. To fix the notations we rewrite the configurations for the set of vertices $I = \{1, 2, 3, 4\}$.

A small reduction automaton starting from the configuration $A^+$ is as follows:
Let us explain the notations: the other configurations of type $A$ are

\[
\begin{array}{cccc}
1 & 4 & 3 & 2 \\
\ast & \ast & \ast & \ast \\
\ast & \ast & a_2 & \ast \\
\ast & \ast & a_3 & \ast \\
\ast & \ast & \ast & \ast \\
a_1 & \ast & \ast & \ast \\
a_2 & \ast & \ast & \ast \\
a_3 & \ast & \ast & \ast \\
a_4 & \ast & \ast & \ast \\
\end{array}
\]

$A^+$

\[
\begin{array}{cccc}
1 & 4 & 3 & 2 \\
\ast & \ast & a_3 & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & a_4 & \ast \\
\ast & \ast & \ast & \ast \\
a_1 & \ast & \ast & \ast \\
a_2 & \ast & \ast & \ast \\
a_3 & \ast & \ast & \ast \\
a_4 & \ast & \ast & \ast \\
\end{array}
\]

$A^-$

the configurations of type $B$ are

\[
\begin{array}{cccc}
1 & 2 & 3 & 4 \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
a_1 & \ast & \ast & \ast \\
a_2 & \ast & \ast & \ast \\
a_3 & \ast & \ast & \ast \\
a_4 & \ast & \ast & \ast \\
\end{array}
\]

$B^+(2)$

\[
\begin{array}{cccc}
1 & 2 & 3 & 4 \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
a_1 & \ast & \ast & \ast \\
a_2 & \ast & \ast & \ast \\
a_3 & \ast & \ast & \ast \\
a_4 & \ast & \ast & \ast \\
\end{array}
\]

$B^-(3)$

and configurations of types $C$ and $D$ are

\[
\begin{array}{cccc}
1 & 2 & 3 & 4 \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
a_1 & \ast & \ast & \ast \\
a_2 & \ast & \ast & \ast \\
a_3 & \ast & \ast & \ast \\
a_4 & \ast & \ast & \ast \\
\end{array}
\]

$C(2,3)$

\[
\begin{array}{cccc}
1 & 2 & 3 & 4 \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
a_1 & \ast & \ast & \ast \\
a_2 & \ast & \ast & \ast \\
a_3 & \ast & \ast & \ast \\
a_4 & \ast & \ast & \ast \\
\end{array}
\]

$C(3,2)$

\[
\begin{array}{cccc}
1 & 2 & 3 & 4 \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
a_1 & \ast & \ast & \ast \\
a_2 & \ast & \ast & \ast \\
a_3 & \ast & \ast & \ast \\
a_4 & \ast & \ast & \ast \\
\end{array}
\]

$D$

\[
\begin{array}{cccc}
1 & 2 & 3 & 4 \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
\ast & \ast & \ast & \ast \\
a_1 & \ast & \ast & \ast \\
a_2 & \ast & \ast & \ast \\
a_3 & \ast & \ast & \ast \\
a_4 & \ast & \ast & \ast \\
\end{array}
\]

$D_*$

In Subsection 6.6 we obtained equivalences $\mp^*(r, d) \xrightarrow{\sim} \br_3(s)$, $s \in \mathbb{N}^4$, where $\mathfrak{A}$ is a BC-box of type $A^+$, $A^-$ or $B$. Since the boxes of BC and BT types are related as explained in the Remark 7.1, thus the canonical small reduction automaton in this case can be obtained from the automaton (27) by gluing states $A^\sigma$ with $A^\sigma_*$ $D$ with $D_*$ :
For the \( \text{BT} \)-boxes we have

\[
\begin{align*}
\begin{array}{cccc}
\ & 1 & 2 & 3 \\
\hline
1 & 0 & 2 & 2 \\
A^+ = A^+_2 \\
2 & 3 & 3 & 2 \\
A^- = A^-_2
\end{array}
&
\begin{array}{cccc}
\ & 1 & 2 & 3 \\
\hline
1 & 0 & 2 & 2 \\
C(2,3) \\
2 & 3 & 3 & 2 \\
C(3,2)
\end{array}
&
\begin{array}{cccc}
\ & 1 & 2 & 3 \\
\hline
1 & 0 & 2 & 2 \\
D-D_7
\end{array}
\end{align*}
\]

and four configurations of type \( B \):

\[
\begin{align*}
\begin{array}{cccc}
\ & 1 & 2 & 3 \\
\hline
1 & 0 & 2 & 2 \\
B^+(2) \\
2 & 3 & 3 & 2 \\
B^+(3)
\end{array}
&
\begin{array}{cccc}
\ & 1 & 2 & 3 \\
\hline
1 & 0 & 2 & 2 \\
B^-(2) \\
2 & 3 & 3 & 2 \\
B^-(3)
\end{array}
\end{align*}
\]

All edge arrows of the poset \( A \) are minimal. The posets \( B \) and \( D \) are of height 2, and the differential biquivers are uniquely defined, by the rule as follows: for a triangle \( i < j < k \) and arrows \( a : j \to i \), \( b : k \to i \), and \( c : k \to j \) the arrow \( b \) is minimal \( \partial(a) = \sum_kbv_i \) and \( \partial(c) = -\sum_iv_ab \) (i.e. the differential in a triangle is as in (24)). For the poset \( C \) one should additionally give a pair of minimal edges: for \( C(2,3) \) they are \( 3 \to 2 \) and \( 4 \to 1 \), for \( C(3,2) \) they are \( 2 \to 3 \) and \( 4 \to 1 \). The the differential of another arrow consist of the path of length 3 and degree one.

**Rank and degree.** For configurations of types \( A \), \( C \) and \( B \) let \( I_{\min} \subset I \) be the subset of minimal vertices and \( I_{\max} \subset I \) be the subset of maximal vertices. For a dimension vector \( s \in \mathbb{N}^4 \) let us introduce new discrete parameters \( (\alpha, \beta) \):

- for a box of type either \( A \) or \( C \) define \( \alpha := \sum_{i \in I_{\min}} s_i \) and \( \beta := \sum_{k \in I_{\max}} s_k \);
- for a box \( B^a(j) \) define define \( \alpha := s_j \sum_{i \in I_{\min}} s_i \) and \( \beta := s_j \sum_{k \in I_{\max}} s_k \).

**Lemma 10.1.** Let \( \Gamma \) be the automaton either (27) or (28) and \( p : \gamma \to \gamma' \) a path on it connecting principal states \( \gamma \) and \( \gamma' \) and taking \( s \mapsto s' \) and \( (\alpha, \beta) \mapsto (\alpha', \beta') \). Then \( \gcd(\alpha, \beta) = \gcd(\alpha', \beta') \).

**Proof.** It is sufficient to check the statement on the shortest paths. For the transitions (i.e. paths paths of length one.) \( A \to B \) or \( C \to B \) we have \( (\alpha', \beta') = (\alpha, \beta) \). For the transitions \( A \to A \), \( B \to C \) or a path of length two \( B \to A \), we have

\[
(\alpha', \beta') = \left\{ \begin{array}{ll}
(\alpha - \beta, \beta), & \text{if } \alpha \geq \beta; \\
(\alpha, \beta - \alpha), & \text{if otherwise.}
\end{array} \right.
\]

That completes the proof. \( \square \)

To obtain the statement of the Theorem 1.2 for Kodaira fibers \( I_3 \) and IV we should replace the pair \( (\alpha, \beta) \) by the rank and degree \( (r, d) \) using Tables 3 and 4. In every case from Tables 3 and 4 but cases 2 and 2' of Table 4 we have \( (\alpha, \beta) = (r-d \mod r, d \mod r) \). The cases 2 and 2' of Table 4 we have respectively \( (\alpha + \beta, \beta) = (r-d \mod r, d \mod r) \) and \( (\alpha, \alpha + \beta) = (r-d \mod r, d \mod r) \).
11. Examples and remarks

Example 11.1. Let $E$ be a curve from the list with 2 components i.e. the Kodaira cycle $I_2$ or the fiber $III$. Let us describe vector bundles on $E$ of rank $r = 9$ and multidegree $(d_1, d_2) = (3, 2)$ using the algorithm 7.2.

1. The normalization bundle $\tilde{F}$ is

$$\tilde{F}|_{L_1} = \mathcal{O}_{L_1}^6 \oplus (\mathcal{O}_{L_1}(1))^3 \text{ and } \tilde{F}|_{L_2} = \mathcal{O}_{L_2}^7 \oplus (\mathcal{O}_{L_1}(1))^2.$$  

2. Since $d = 5 < 9 = r$ thus the input state for the automaton is $A^+$ for $E = I_2$ and $A^+(1)$ for $E = III$; and the dimension vector is $s = (s_1, s_2, s_3) = (4, 2, 3)$.

3. Taking on automaton (25) the path

$$p : A^+ \xrightarrow{(12)} B \xrightarrow{(31)} A^- \xrightarrow{(23)} A^- \xrightarrow{(32)} B \xrightarrow{(13)} A^+ \xrightarrow{(12)} B \xrightarrow{(31)} A^-$$

we get the reduction of sizes:

$$(4, 2, 3) \xrightarrow{(12)} (2, 2, 3) \xrightarrow{(31)} (2, 2, 1) \xrightarrow{(23)} (2, 1, 1) \xrightarrow{(23)} (2, 0, 1) \xrightarrow{(32)} (2, 0, 1) \xrightarrow{(13)} (1, 0, 1) \xrightarrow{(12)} (1, 0, 1) \xrightarrow{(31)} (1, 0, 0).$$

4. Reversing the path $p$ we construct a canonical form of the matrix $M \in \text{Br}_3(4, 2, 3)$.  

If $E$ be Kodaira cycle $I_2$ then

Let us construct the canonical form for the tacnode curve. Besides zeros we also use the empty spaces to mark out blocks, where zeros appears for some general reasons and the corresponding box contains no such arrow. Note that the order of row and
column blocks are chosen in such a way that the matrices have block triangular form (probably with some additional holes).

\[
\begin{bmatrix}
1 & \lambda & 1 \\
0 & 1 & 3
\end{bmatrix} \quad \begin{bmatrix}
1 & 3 \\
0 & 1 & 3
\end{bmatrix} \quad \begin{bmatrix}
1 & 3 \\
0 & 1 & 3
\end{bmatrix}
\]

\[
\begin{bmatrix}
1 & 3 & 1 \\
0 & 1 & 3
\end{bmatrix} \quad \begin{bmatrix}
1 & 3 & 0 \\
0 & 0 & 1 \\
0 & 0 & 3
\end{bmatrix} \quad \begin{bmatrix}
1 & 3 & 0 \\
0 & 0 & 1 \\
0 & 0 & 3
\end{bmatrix}
\]

\[

\]

**Remark 11.2.** For a Kodaira fiber II, III and IV the parameter \( \lambda \) of the canonical form of \( M(\lambda) \) can be moved to any place on the diagonal, as well as it can be distributed as \( \frac{\lambda}{r} \) to each diagonal entries. This way the canonical form resembles to the Jordan normal form. For instance in the last example we get:

\[
\begin{bmatrix}
\frac{\lambda}{9} & 0 & 0 \\
0 & \frac{\lambda}{9} & 0 \\
0 & 0 & \frac{\lambda}{9}
\end{bmatrix} \quad \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 3
\end{bmatrix} \quad \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 3
\end{bmatrix}
\]

**12. Properties of simple vector bundles**

**12.1. Tensor products.** Let \( \Lambda := \mathbb{k}^* \) if \( E \) a Kodaira cycle and \( \mathbb{k} \) if \( E \) is a Kodaira fiber (\( \Lambda \cong \text{Pic}^0(\ell, \ldots, \ell)(E) \)). Let \( \mathcal{E}(\lambda) \in \mathcal{B}^s_E(r, d) \) and \( \mathcal{L}(\lambda) \in \text{Pic}_E^0(\ell, \ldots, \ell) \) be respectively a simple vector bundle and the line bundle with the matrix \( M = M(\lambda) \in Br_\mathfrak{A} \) and the parameter \( \lambda \in \Lambda \).
Proposition 12.1. For $\lambda_1, \lambda_2 \in \Lambda$ we have

$$\mathcal{E}(\lambda_1) \otimes \mathcal{L}(\lambda_2) = \begin{cases} 
\mathcal{E}(\lambda_1 \cdot \lambda_2) & \text{if } E \text{ is a Kodaira cycle } I_1, I_2 \text{ or } I_3; \\
\mathcal{E}(\lambda_1 + r \cdot \lambda_2) & \text{if } E \text{ is a Kodaira fiber } II, III \text{ or } IV.
\end{cases}$$

Proof. Let $(\tilde{F}, V, \tilde{\mu}'(\lambda_1))$ and $(\tilde{O}, \mathcal{O}_S, \tilde{\mu}''(\lambda_2))$ be the triples of the vector bundle $\mathcal{E}(\lambda_1)$, the line bundle $\mathcal{L}(\lambda_2)$. Then the triple of the vector bundle $\mathcal{E}(\lambda_1) \otimes_\mathcal{O} \mathcal{L}(\lambda_2)$ is $(\tilde{F}, V, \bar{\mu} := \tilde{\mu}'(\lambda_1) \otimes \tilde{\mu}''(\lambda_2))$.

For Kodaira fiber I: $\mathcal{O}_S = k$ and $\mathcal{O}_S = k \oplus k$, $\tilde{\mu}'(\lambda_1)) = (I, M(\lambda_1))$ and $\tilde{\mu}''(\lambda_2)) = (1, \lambda_2)$.

$$\tilde{\mu} = \tilde{\mu}'(\lambda_1) \otimes \tilde{\mu}''(\lambda_2)) = (I, M(\lambda_1) \cdot (1, \lambda_2) \cdot (\lambda_2, M(\lambda_1)) = (I, M(\lambda_1 \cdot \lambda_2^2)).$$

To obtain the last equality one should reduce $\lambda_2 \cdot M(\lambda_1)$ to the canonical form preserving the first $\mathbb{I}$-matrix. Let as illustrate it on the case $r = 2$ :

$$(\tilde{\mu}(0), \tilde{\mu}(\infty)) = \begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & \lambda_2 \\ 1 & \lambda_1 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & \lambda_2 \\ 0 & 1 & \lambda_1 \lambda_2 & 0 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

For Kodaira fiber II: $\mathcal{O}_S = k$ and $\mathcal{O}_S = k[\varepsilon]/\varepsilon^2$, $\tilde{\mu}'(\lambda_1)) = I + \varepsilon \cdot M(\lambda_1)$ and $\tilde{\mu}''(\lambda_2)) = 1 + \varepsilon \cdot \lambda_2$.

$$\tilde{\mu} = \tilde{\mu}'(\lambda_1) \otimes \tilde{\mu}''(\lambda_2)) = (I + \varepsilon \cdot M(\lambda_1)) \cdot (1 + \varepsilon \cdot \lambda_2) = I + \varepsilon \cdot (M(\lambda_1) \cdot (1 + \lambda_2 \cdot \mathbb{I}) = I + \varepsilon \cdot M(\lambda_1 + \lambda_2).$$

The last equality follows immediately if we rewrite $M(\lambda)$ in the “diagonal” form (29). For example, if $r = 2$ and $d = 1$ we have

$$\tilde{\mu} = \tilde{\mu}(0) + \varepsilon \tilde{\mu}(0) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \varepsilon \cdot \begin{pmatrix} \lambda_1 \lambda_2 / 2 \\ 0 \\ 0 \\ \lambda_2 / 2 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \varepsilon \begin{pmatrix} 1 \\ \lambda_1 \lambda_2 / 2 \end{pmatrix}.$$

For Kodaira cycles $I_2$, $I_3$ and fibers III and IV the calculations should be carried out on each component. On the first component the picture is similar to the cases of I and II. On the other components we have $\tilde{\mu}_k = \tilde{\mu}_k'$.

Example 12.2. If $r = 3$ and $d = (1, 1)$ for Kodaira cycle $I_2$ we have

$$\begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & \lambda_1 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & \lambda_2 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & \lambda_1 \lambda_2 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 \end{pmatrix}.$$
and for Kodaira fiber III taking $\lambda := \lambda_1 + 3\lambda_2$ we have

$$
\begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix} + \varepsilon_1 \begin{pmatrix}
\lambda_1 & 1 & 0 \\
0 & 0 & 1 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix} + \varepsilon_2 \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix}
\cdot \begin{pmatrix}
1 + \varepsilon_1 \\
0 \\
0 \\
1 + \varepsilon_2
\end{pmatrix} =
\begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix} + \varepsilon_1 \begin{pmatrix}
\lambda & 1 & 0 \\
0 & 0 & 1 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix} + \varepsilon_2 \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix}.
$$

12.2. Morphisms.

**Proposition 12.3.** Let $E$ be one of the curves from Table (1). Then

$$
\text{Hom}_E(\mathcal{E}(\lambda_1), \mathcal{E}(\lambda_2)) = 0.
$$

**Proof.** From the equivalence $\text{VB}^*_E(r, s) \sim \text{Br}_d(s)$ we have:

$$
\text{Hom}_E(\mathcal{E}(\lambda_1), \mathcal{E}(\lambda_2)) = \text{Hom}_A(M(\lambda_1), M(\lambda_2))
$$

Let $(S, S')$ or $S \in \text{Hom}_A(M(\lambda_1), M(\lambda_2))$. If $r = 1$ and $(S, S') \neq 0$ then $S' = S \in k^*$ and since $M(\lambda_1) = [\lambda_1]$ and $M(\lambda_2) = [\lambda_2]$, we get a contradiction: $S\lambda_1 S^{-1} = \lambda_2$. Recall that a path $p$ on a small reduction automaton gives an equivalence of the categories $\text{Br}_d(s) \xrightarrow{p} \text{Br}_d(s')$, where $s' \leq s$. Thus the statement follows by induction on the dimension vector $s$ along the path $p$. \qed

**Remark 12.4.** By the same approach one can also describe torsion free sheaves which are not vector bundles. We are going to consider this situation in further works. One can also consult [Bod07] Sections 3.3, 4.5 and 7.7 about torsion free sheaves on cuspidal and tacnode curves.
