keywords: Spatial point analysis, Nearest neighbor method, Charged particle, Ion track

1. Introduction

Charged particle irradiation has attracted growing interest in cancer radiation therapy, because charged particle irradiation is expected ultimately to attack one tumor cell without damage to peripheral cells [1]. One of the essential matters to be solved for medical use of the charged particle is the spatial pattern analysis which an ion track pattern is uniformly distributed, randomly distributed, or clustered, though the charged ion particles are generally considered to be randomly irradiated.

We have developed a sensitive method for visualization of single ion track at ultra-high resolution using common polymer film, polyacrylic acid (PAA) -N,N'-methylene bisacrylamide (MBAAm) blend film, by atomic forced microscopy (AFM). The visualization method is expected to be successfully applied to spatial pattern analysis of ion track with ultra-high spatial resolution [2].

Nearest neighbor analysis is widely used in various fields, such as population ecology [3], epidemiology [4], and bio-imaging [5]. In this analysis, spatial pattern is determined easily to measure the nearest neighbor distance of ion track. Here, we report spatial point analysis of ion track pattern by the combination of ion track visualization with PAA-MBAAm films and the nearest neighbor analysis, demonstrating fairly clear random special distribution of ion tracks.

2. Experimental

PAA-MBAAm blend films on a silicon substrate (1.0 × 1.0 cm²) were prepared by spin-casting with a methanol solution of 3 wt% PAA with MBAAm (PAA/MBAAm = 75/25). The thickness of the films was adjusted to 500 nm. The films were irradiated in a vacuum chamber (<10⁻⁴ Pa) with 490 MeV ¹⁹²Os³⁰⁺ ion beams from the cyclotron accelerator at Takasaki Advanced Radiation Research Institute, Japan Atomic Energy Agency. The expected fluence of the incident ions varied from 5.0 × 10⁷ to 2.5 × 10⁸ ions cm⁻². After irradiation, the films were reserved in the desiccator with dry silica gel under reduced pressure at 25°C. The reserved films were moved into the desiccator saturated with water vapor at 25°C. After standing for 3 min, the film surfaces were observed by AFM. The AFM images were obtained with a Naio AFM (NanoSurf, Switzerland) operated in tapping mode in air at 25°C. Scan size was over 6 × 6 μm. For the fluence of 5.0 × 10⁷ ions cm², 16 points were randomly scanned in the film. For the fluence of 1.0 × 10⁸ and 2.5 × 10⁸ ions cm², 8 points were randomly scanned in the film.

The spatial point analysis of ion track pattern was carried out by using nearest neighbor analysis [3]. To minimize the edge effect, nearest neighbor analysis was performed in the smaller
The observed mean nearest neighbor distance (NND) of ion tracks, represented by \( r_\text{A} \), is equal to

\[
\overline{r}_\text{A} = \frac{1}{N} \sum r
\]

(1)

where \( N \) is the total number of ion tracks in analysis areas and \( r \) is the distance from a given individual to its nearest neighbor. The expected mean NND of ion tracks in completely random distribution, represented by \( \overline{r}_E \), is equal to

\[
\overline{r}_E = \frac{1}{2(N/A)^{1/2}}
\]

(2)

where \( A \) is the size of analysis area. The standard error of expected mean NND, represented by \( \sigma_{\overline{r}_E} \), is equal to

\[
\sigma_{\overline{r}_E} = \left( \frac{4 - \pi}{4\pi N^2 A} \right)^{1/2} \left( \frac{0.26136\pi A^{1/2}}{N} \right)
\]

(3)

The standard variate of the normal curve, represented by \( c \), is equal to

\[
c = \frac{\overline{r}_\text{A} - \overline{r}_E}{\sigma_{\overline{r}_E}}
\]

(4)

The measure of the degree to which observed distribution approaches or departs from random expectation with respect to NND, represented by \( R \), is equal to

\[
R = \frac{\overline{r}_\text{A}}{\overline{r}_E}
\]

(5)

In a typical random pattern, the value of \( R \) is 1. The value of \( R < 1 \) indicates clusterd, while the value \( R > 1 \) indicating regular spacing.

### 3. Results and discussion

Figure 1a shows the AFM image of the 4 different areas in the PAA-MBAAm blend films irradiated with 490 MeV \(^{192}\text{Os}^{30+} \) ion beams at expected fluence of \( 1.0 \times 10^8 \) ions cm\(^{-2} \) and exposed to saturated water vapor. The irradiated spatial points of the film swelled significantly, giving corresponding peaks of the bright spots in the Figure. Ion tracks are observed to be inhomogeneous patterns in a certain area. To analyse spatial pattern, each NND of ion tracks in analysis areas (200 \( \mu \text{m}^2 \)) was measured. Figure 1b shows the NND histogram at expected fluence of \( 1.0 \times 10^8 \) ions cm\(^{-2} \) (= 1.0 ions \( \mu \text{m}^{-2} \)). In analysis areas, 140 ion tracks were counted and the observed fluence is 0.70 ions \( \mu \text{m}^{-2} \), which is slightly lower than the fluence incident charged particles estimated from transient current monitored with Faraday-cup measurement. (1.0 ions \( \mu \text{m}^{-2} \)). For all 140 ion tracks in 200 \( \mu \text{m}^2 \), the observed mean NND is 611 nm (Equation (1)). If these charged ion particles were randomly irradiated, the expected NND is 598 nm with a standard error of 26 nm (Equations (2) and (3)). The value of standard normal variate is a quite small (0.51), and the value of \( R \) (1.02) was close to 1 (Equations (4) and (5)). There are little difference between observed ion track distribution and theoretical random pattern, indicating that the ion track distribution is a random pattern.

Fig. 1. (a) AFM images of the 4 different areas in the PAA-MBAAm film with 490 MeV \(^{192}\text{Os}^{30+} \) ion beam at expected fluence of \( 1.0 \times 10^8 \) ions cm\(^{-2} \). (b) NND histogram (\( n = 140 \)).

To examine the effect of the fluence on the spatial pattern of ion track, the nearest neighbor method was also applied to the expected fluence of 0.50 and 2.5 ions \( \mu \text{m}^{-2} \). Ion tracks were increased with increasing the fluence, as shown in Fig. 2a. The distribution of NND significantly changed depending on the fluence (Fig. 2b). The each observed fluence is 0.38 and 1.5 ions \( \mu \text{m}^{-2} \), respectively. The observed number of ion tracks
in a unit area is directly proportional to the fluence of incident charged particles estimated from transient current monitored with Faraday-cup measurement. Table 1 summarizes nearest neighbor analysis of ion track pattern. These results indicate that the ion track distribution is well interpreted by a random pattern model in the area, which is also independent of fluence.

To evaluate the details of spatial pattern of ion track, the cumulative probability of point event distances to the nearest ion track were calculated from the distribution of NND (Fig. 3).

Table 1. Comparison of the various fluence in the application of the nearest neighbor method.

|                  | Run 1 | Run 2 | Run 3 |
|------------------|-------|-------|-------|
| Expected fluence (ions/µm²) | 0.50  | 1.0   | 2.5   |
| Scan area (µm²)   | 400   | 200   | 200   |
| Number of ion tracks | 151   | 140   | 296   |
| Observed fluence (ions/µm²) | 0.38  | 0.70  | 1.5   |
| Observed mean NND (nm)    | 812   | 611   | 422   |
| Expected mean NND (nm)    | 816   | 598   | 411   |
| σr (nm)           | 35    | 26    | 12    |
| c                 | -0.05 | 0.51  | 0.88  |
| R                 | 1.00  | 1.02  | 1.03  |

In a theoretical random pattern, the cumulative probability, \( F(r) \), is

\[
F(r) = 1 - e^{-\frac{\pi r^2}{A}} \quad (6)
\]

In the all fluence, the observed cumulative probabilities agree mostly with the theoretical cumulative probability. Random patterns, again, are reproducible to the distribution of ion tracks,
and the charged ion particle rarely interferes with another charged ion particles at low fluence. This is the first report that nearest neighbor method was also applied to track pattern. This analysis will be contributed to not only fundamental study but also applied study such as cancer therapy.
