Dear Sirs,

Chronic obstructive pulmonary disease (COPD) represents a leading cause of morbidity and mortality in ageing populations.1 However, there is a significant dissociation between guideline recommendations for managing COPD and clinicians’ practice. Several studies have suggested that adoption of the GOLD guidelines has been suboptimal. For the first time, the revised GOLD Guidelines published in 2011 suggest a combined assessment of symptoms, the degree of airflow limitation as measured by spirometry, and the risk of future exacerbation, with patients grouped into four different classes in order to guide therapy.

We therefore conducted a study to compare the regular pharmacological treatment of stable COPD patients in clinical practice with the previous (2010) and current (2011) GOLD guidelines and to investigate whether the new classification of patients improved adherence to GOLD recommendations.

A cohort of 127 consecutively selected patients with stable COPD (122 male, mean age 69.6 ± 8.8 years (range: 47-83)) were enrolled in the study. COPD diagnosis was based on global respiratory clinic, University hospital of Larissa, University of Thessaly and all patients provided written informed consent.

A total of 117 patients (92.1%) received bronchodilators. Long-acting antimuscarinic agents (LAMAs) were the most prescribed drugs, being included in the standard therapy of 98 patients (77.1%), and used as monotherapy in 15 patients (11.8%). Long-acting β2-agonists (LABAs) were prescribed in 86 patients (67.7%). Triple therapy (LAMA, LABA and inhaled corticosteroid (ICS)) was used in 57 patients (44.8%) at all stages of the disease.

versions of the guidelines. Observed adherence to treatment differed from expected in all stages and groups, whereas the differences between groups were marginally statistically significant (p=0.048) only in the case of the 2011 guidelines (Group B differed from the others, exhibiting the lowest adherence percentage of -33%), while no differences between stages were observed in the case of the 2010 guidelines (p=0.0921). However, the combined assessment seemed to benefit more high risk patients, as the percentage dropped to 10.2% and 0% in Groups C and D respectively.

The results of our study show that the rate of adherence to the GOLD guideline has increased from 40.9% with the 2010 version to 70.1% with the 2011 version. Nevertheless, over-treatment remains high in low risk COPD patients.

There are several reasons which might explain the improved adherence to the latest 2011 recommendations. The new categories have led to patients being categorised as having ‘worse’ COPD; consequently, combined medical treatment including ICS as well as LAMAs and LABAs which would have been regarded as over-treatment according to the 2010 guideline is now considered correct according to the 2011 guideline. Moreover, the new guideline includes a wider choice of second choice respiratory medications, so patients previously considered to be over-treated are now treated appropriately; 96.2% of patients in Group D (2011 guidelines) are being treated appropriately as opposed to 57.9% in Stage IV (2010 guidelines).

Compliance with the new 2011 guideline is low, despite the appropriate classification of patients and the strategy of early implementation of COPD guidelines. This is not a domestic phenomenon. Recent international research reveals discrepancies between expected and observed treatment regimes. Asche et al. found that 66% of their study population were prescribed medications inconsistent with their spirometry results, while other researchers suggest less than optimal adherence with recommended drug therapy treatment for COPD patients based on GOLD guidelines.

The appropriate use of COPD medications is both cost effective and clinically beneficial for patients and stakeholders. Nevertheless, physicians’ knowledge and use of guidelines seems to be insufficient, with deficits in the pharmacological treatment of COPD. Changes in health care systems must include more effective ways to transfer knowledge into clinical practice. High quality education may raise the standards of health care provided for patients with COPD. However, as real life often demands an individualised treatment approach, the contribution of other factors to COPD treatment (co-morbidities, access to health care facilities, patient educational level) also needs to be investigated in the future.
