(Dated: July 12, 2017)

Using simple symmetry arguments we classify the ungauged $D = 4$, $N = 2$ supergravity theories, coupled to both vector and hyper multiplets through homogeneous scalar manifolds, that can be built as the product of $N = 2$ and $N = 0$ matter-coupled Yang-Mills gauge theories. This includes all such supergravities with two isolated exceptions: pure supergravity and the $T^3$ model.

I. INTRODUCTION

A field theoretic incarnation of “gravity = gauge × gauge” theory was developed in [1–7]. In particular, one can form the product of fields belonging to two independent (super) Yang-Mills gauge theories, which we will refer to as the Left and Right factors. Importantly, the product maps the content, symmetries and field equations of the factors into those of a (super) gravity theory. We will refer to this construction here as squaring Yang-Mills. In the present contribution we use this framework to classify the ungauged $D = 4, \mathcal{N} = 2$ supergravity theories, coupled to both vector and hyper multiplets through homogeneous scalar manifolds, that can be built as the square of Yang-Mills.

A prior, related but distinct, realisation of the gravity = gauge × gauge picture is given by the Bern-Carrasco-Johansson (BCJ) double-copy construction of scattering amplitudes. It has been conjectured [8, 9], with substantial evidence [10–16], that the scattering amplitudes of certain gravity theories are the double-copy, in a precise sense, of amplitudes belonging to two independent Yang-Mills theories. The paradigmatic example is given by $\mathcal{N} = 8$ supergravity as the product of two $\mathcal{N} = 4$ Yang-Mills theories, which due to the high degree of symmetry is also the simplest possible case. These remarkable amplitude relations rely crucially on the Bern-Carrasco-Johansson (BCJ) colour-kinematic duality [17], which has been established at tree-level but remains conjectural for arbitrary loops, and have been used to demonstrate the existence of unexpected cancellations throwing open the possibility that $\mathcal{N} = 8$ supergravity may be perturbatively finite [11, 16]. There is now a growing list of double-copy constructible theories in diverse dimensions [18–27], conformal gravity being the latest addition [28, 29]. Moreover, the BCJ amplitude prescription has recently been generalised to include certain curved background spacetimes [30]. At the same time, the paradigm has been extended beyond amplitudes in a variety of directions [1–4, 6, 7, 31–40]. These remarkable and continually developing relations raise three natural questions:

i) Why does the correspondence work? Can we prove the BCJ colour-kinematic conjecture and pinpoint its origins?

ii) How deep is the correspondence? That is, how far beyond amplitude relations can it be taken?

iii) How general is the correspondence? What gravitational theories admit a Yang-Mills squared origin; are the factorisable theories special in some regard?

Here we address a corner of (iii), by significantly extending the domain of ungauged $D = 4, \mathcal{N} = 2$ supergravity theories that are the square of Yang-Mills and hence may be in principle double-copy constructible.

We should be clear about our definition of squaring: the gravitational theory is defined by the totality generated by the two gauge factors. In terms of the double-copy this implies: (1) all gravity scattering amplitudes can be factorised, in the BCJ sense, into the product of amplitudes of the two gauge theories and (2) all double-copies of the gauge theory amplitudes generate an amplitude belonging to the corresponding gravitational theory. For example, pure Einstein gravity is not double-copy constructible in this sense. Although all its amplitudes may be systematically double-copy constructed by consistently cancelling the would-be axion-dilaton sector with the product of “ghost” chiral fermion amplitudes [22], thus satisfying (1), the spin-1 states arising in the ghost × ghost sector must be explicitly (but consistently) excluded, thus failing (2).

In the attempt to classify all supergravity theories with a Yang-Mills origin, the squaring and double-copy approaches are complementary in the following sense: starting with the double-copy, one finds the most general BCJ-friendly Yang-Mills candidate factors, then double-copies the amplitudes and lists the supergravity theories generated. Demanding BCJ duality constrains the couplings and symmetries of the gauge factors and one should be able to check that the resulting supergravities have the expected symmetries in the squaring sense. Alternatively, starting with squaring, one studies case-by-case whether or not each known supergravity theory admits a factorisation using symmetry principles, and only then checks for BCJ compatibility. These complementary pictures have led to a good understanding of a large subset of gravity theories: for pure super Yang-Mills factors we have a complete classification of all supergravity theories generated for spacetime dimensions $3 \leq D \leq 10$ [3, 19, 41, 42]; using a factorisable orbifold construction and an $\mathcal{N} = 0$ Yang-Mills factor, this was generalised to include a number of additional $\mathcal{N} = 4, 2, 1$ matter-coupled supergravity theories [18]; in [22] the colour-kinematic duality was generalised to include non-adjoint representations of the gauge group, allowing for fundamental matter-coupled Yang-Mills factors and a broader class of matter-coupled gravity theories; this was subsequently used to double-copy construct all ungauged $D = 5, 4, \mathcal{N} = 2$

---

1 As it stands this can of course only be established in general at tree-level, with supporting evidence from case-by-case examples of loop-level amplitudes. Our present analysis is explicitly tree-level only.
supergravity theories coupled to vector multiplets through a homogeneous scalar manifold, using half-hyper multiplets carrying a pseudo-real gauge group representation [25]. Building on such principles, the symmetry arguments used in the present work were developed to construct all twin supergravities in [5]. In summary, so far the classification includes all greater than half-maximal supergravities, all the half-maximal supergravities coupled to vector multiplets, some of the quarter maximal supergravities coupled to vector multiplets and a small set of simple theories outside these classes. Note, in all cases treated thus far the scalars parametrise a homogeneous manifold, however, for $N \leq 2$, supergravity theories with non-homogeneous scalar manifolds are also possible. The square or double-copy origin of such theories remains a compelling open question.

Here, we adopt the squaring methodology to extend the domain of [3, 5, 18, 19, 22, 25, 41, 42] to include $N = 2$ ungauged supergravity theories coupled to both vector and hyper multiplets with homogeneous scalar manifolds using an $N_L = 2$ Yang-Mills theory coupled to a single half-hyper multiplet and a unique class of $N_R = 0$ Yang-Mills gauge theories parametrised by six integers. It is shown that, with the single exception of the $T^3$ model and pure $N = 2$ supergravity, the classification includes all such supergravity theories with symmetric scalar cosets. For the non-symmetric theories including hyper multiplets, we propose a candidate squaring procedure; there is a seemingly unique possibility involving a restriction to a diagonal subgroup of the Left and Right global symmetries. Although the origin of such a restriction remains unclear, our analysis suggests that any $[N_L = 2] \times [N_R = 0]$ double-copy amplitude construction will reflect this requirement. Note, since the hyper multiplets are insensitive to dimensional reduction and it is only the scalar fields of the Right theory that contribute to this sector, our construction generalises trivially in all cases to $D = 6, 5, 4, 3$.

| $Q$ | $R$ | $\text{Type}_N$ | $f$ | Content under $U(1)^{st} \times R$ |

**TABLE I.** On-shell helicity states of all $D = 4$ supermultiplets. Here $Q$ counts the number of supercharges, $R$ denotes the global $R$-symmetry group, $\text{Type}_N$, the class of $N$-extended supermultiplet and $f$ is number of degrees of freedom. The $N$-extended gravity, vector and spinor multiplets are denoted by $G_N$, $V_N$ and $C_N$, respectively. Note, $C_2$ and $H_2$ are used to distinguish half-hyper and full-hyper multiplets, respectively. Although $V_4$ and $V_4$ are identical as isolated gauge multiplets, when coupled to supergravity they must be distinguished. Similarly, $G_7$ and $G_8$ have identical content and as interacting theories are identical despite having a priori distinct symmetries. Finally, we use $A$, $\lambda$ and $\phi$ to denote the smallest $N = 0$ vector, spinor and scalar multiplets, respectively.

The remaining sections are organised as follows. In section II we summarise the class of supergravity theories considered here. In section III we consider the Yang-Mills origin of these theories. We first outline the general principles in section III A. Then we include only vector multiplet couplings in section III C 1, which builds on the set of supergravities derived in [25] by including a detailed analysis of the minimally coupled sequence and the $T^3$ model. Finally, in
In this section we itemize the $D = 4$, $\mathcal{N} = 2$ supergravity theories under consideration, specifically those with scalar fields parametrising a homogeneous manifold, highlighting their field content and symmetries as required for the Yang-Mills squared construction given in section III. We consider both vector and hyper multiplets; the total homogeneous scalar manifold $\mathcal{M}$ factors into a special Kähler (SK) manifold $G/H$, parametrised by the scalars belonging to the vector multiplets, and a quaternionic (Q) manifold $G/H_q$, parametrised by the scalars belonging to the hyper multiplets,

$$\mathcal{M} \cong \frac{G}{H} \times \frac{G}{H_q}$$

In section II.A and section II.B we present the possible couplings to vector and hyper multiplets, respectively, under the assumption that the scalar manifold is homogeneous.

### A. Vector multiplets

When coupling $\mathcal{N} = 2$ supergravity to vector multiplets the scalar manifold must be projective SK [43–45]. In the non-symmetric case the possible classes of scalar manifolds are indexed by three integers $(q, P, \tilde{P})$ as described in section II.A.1. If the scalar manifold is symmetric there are three classes: (i) the generic Jordan sequence indexed by a single integer, $(q, P, \tilde{P}) = (q, 0, 0)$, (ii) the four magic supergravities [46–48] for which $(q, P, \tilde{P}) = (n, 1, 0)$, where $n = \dim \mathfrak{A} = 1, 2, 4, 8$, and (iii) the minimally coupled sequence indexed by a single integer, $(q, P, \tilde{P}) = (-2, P, 0)$. In addition to these classes, we have the isolated case of the $T^3$ model [49, 50], which although underpinned by a Jordan algebra is not a part of the generic Jordan sequence [51, 52]. In the absence of hyper scalars $G/H_q$ reduces to a trivial $SU(2)/SU(2)$ factor, where the denominator corresponds to the global R-symmetry.

#### 1. Non-symmetric

In the non-symmetric homogeneous cases the scalar manifold is:

$$\frac{G}{H} \times \frac{SU(2)}{SU(2)} = SO(1, 1) \times \frac{SO(q + 2, 2)}{SO(q + 2) \times U(1)} \times \frac{S_q(P, \tilde{P})}{S_q(P, \tilde{P})} \times \frac{SU(2)}{SU(2)} \times \left[(\text{spin, def}, 1)^1 \times (1, 1, 1)^2\right],$$

where spin indicates the spinor representation of $SO(q + 2, 2)$ and def the defining representation of $S_q(P, \tilde{P})$. Here, $(q, P, \tilde{P})$ are integers, which fix the number of vector multiplets present, the symmetry groups and representations carried by the field content, as described in Table II.

The content is $G_2 \oplus (1 + q + 2 + r)V_2$, where $r$ is fixed by $P, \tilde{P}$ as in Table II. Under the maximal reductive global compact symmetry group

$$U(1)^{\text{st}} \times H \times SU(2) = U(1)^{\text{st}} \times SO(q + 2) \times S_q(P, \tilde{P}) \times SU(2) \times U(1),$$

where $U(1)^{\text{st}}$ is the spacetime little group, the content carries the representations:

$$\begin{align*}
(1, 1, 1)^0_4 + (1, 1, 1)^0_4 \\
(1, 1, 2)^1_3 + (1, 1, 2)^{-1}_3 \\
(1, 1, 1)^2_2 + (1, 1, 1)^{-2}_2 + (1, 1, 1)^{-2}_2 + (q + 2, 1, 1)^0_2 + (q + 2, 1, 1)^0_2 + (r, 1)^{-1}_2 + (\mathfrak{F}, 1)^1_2 \\
(1, 1, 2)^{-1}_1 + (1, 1, 2)^1_1 + (q + 2, 1, 2)^1_1 + (q + 2, 1, 2)^{-1}_1 + (r, 2)^0_1 + (\mathfrak{F}, 2)^0_1 \\
(1, 1, 1)^0_0 + (1, 1, 1)^0_0 + (q + 2, 1, 1)^2_0 + (q + 2, 1, 1)^0_2 + (r, 1)^0_0 + (\mathfrak{F}, 1)^{-1}_0.
\end{align*}$$
TABLE II. The groups $SO(q + 2) \times S_q(P, \hat{P})$ and their representations $r$ for the various allowed values of $(q, P, \hat{P})$.

| $q$ | $SO(q + 2)$ | $S_q(P, \hat{P})$ | $r$ | $\mathfrak{r}$ | $r(q, P, \hat{P})$ |
|-----|-------------|-----------------|-----|------------|-------------------|
| −1  | $-//-$      | $SO(P)$         | $\mathbb{P}$ | $\mathbb{P}$ | $P + \hat{P}$    |
| 0   | $U(1)$      | $SO(P) \times SO(\hat{P})$ | $(\mathbb{P}, 1)_{-\gamma} + (1, \hat{\mathbb{P}})_{-\gamma}$ | $(\mathbb{P}, 1)_{\gamma} + (1, \hat{\mathbb{P}})_{\gamma}$ | $P$          |
| 1   | $SU(2)$    | $SO(P)$         | $(2, \mathbb{P})$ | $(2, \mathbb{P})$ | $2P$          |
| 2   | $SU(2)^2$  | $U(\hat{P})$   | $(\mathbb{2}, 1, \mathbb{P})_{-\gamma} + (1, 2, \mathbb{P})_{-\gamma}$ | $(2, 1, \mathbb{P})_{\gamma} + (1, 2, \mathbb{P})_{\gamma}$ | $4P$         |
| 3   | $Sp(2)$    | $Sp(P)$        | $(4, 2\mathbb{P})$ | $(4, 2\mathbb{P})$ | $8P$          |
| 4   | $SU(4)$    | $Sp(P) \times Sp(\hat{P})$ | $(4, 2\mathbb{P}) + (4, 2\hat{\mathbb{P}})$ | $(\mathbb{4}, 2\mathbb{P}) + (\mathbb{4}, 2\hat{\mathbb{P}})$ | $8P + 8\hat{P}$ |
| 5   | $SO(7)$    | $Sp(P)$        | $(8, 2\mathbb{P})$ | $(8, 2\mathbb{P})$ | $16P$         |
| 6   | $SO(8)$    | $U(\hat{P})$   | $(8, \mathbb{P}) + (8, \hat{\mathbb{P}})$ | $(8, \mathbb{P}) + (8, \hat{\mathbb{P}})$ | $16P$         |
| 7   | $SO(9)$    | $SO(P)$        | $(16, \mathbb{P})$ | $(16, \mathbb{P})$ | $16P$         |
| 8   | $SO(10)$   | $SO(P) \times SO(\hat{P})$ | $(16, \mathbb{P}, 1) + (16, 1, \hat{\mathbb{P}})$ | $(\mathbb{16}, \mathbb{P}, 1) + (\mathbb{16}, 1, \hat{\mathbb{P}})$ | $16P + 16\hat{P}$ |

Note that the $1, q + 2$ and $r$ vector multiplets fall into three distinct sectors with different representation theoretic properties. As we shall see, this observation follows from the squaring construction; the three sets come from three different terms appearing in the product of the Left and Right theories. Here, $r = 2^{[(q + 1)/2]} \dim \def$, where the square parentheses denote the integer part. The $SO(q + 2) \times S_q(P, \hat{P})$ representations $r$ are summarised in Table II for the various values of $(q, P, \hat{P})$. See also Table 3 of [53], where for $q = 3$ and 5 the group $S_3(P, \hat{P})$ is also identified with $U(P, H)$. Note, $S_q(P, \hat{P})$ enjoys mod 8 Bott periodicity in $q$, following the standard $R, R \oplus R, R, C, H, H \oplus H, H, C \ldots$ pattern, and is symmetric in $P$ and $\hat{P}$. For $S_q(P, \hat{P}) \cong U(P)$, the defining representation together with its conjugate representation, $\mathbb{P} \oplus \mathbb{P}$, admits both a symplectic and a symmetric real quadratic form that should be used for a pseudo-real or real gauge group representation respectively, where in the latter case the $Sp$ and $SO$ groups of Table II are interchanged.

2. *Generic Jordan*

There are particular choices of $(q, P, \hat{P})$ for which the non-reductive terms of (2) are accompanied by their oppositely charged, under the global $SO(1, 1)$, counterparts. As described in section III C, see in particular the discussion around (72), this implies the so-called *1st enhancement* to $SL(2, \mathbb{R})$. In these cases, the resulting coset spaces are symmetric. The simplest example occurs for $(q, P, \hat{P}) = (q, 0, 0)$, implying that $r = 0$, which yields the generic Jordan series. Alternatively, the generic Jordan series is also given by $(q, P, \hat{P}) = (0, P, 0)$ or $(0, 0, \hat{P})$ [53]. In this case, the scalar coset is:

$$
G \times SU(2) \over H = SU(1, 1) \times SU(q + 2) \times SU(2) \over SU(q + 2) \times U(1) \times U(1) \times SU(2).
$$

(5)

The content is $G_2 \oplus (1 + q + 2)V_2$ and under

$$
U(1)^{st} \times H \times SU(2) = U(1)^{st} \times SO(q + 2) \times SU(2) \times U(1) \times U(1)
$$

(6)

carries the following representations:

$$
(1, 1)^{(0, 0)}_{-1} + (1, 1)^{(0, 0)}_{1} + (1, 2)^{(1, 1)}_{-1} + (1, 2)^{(1, 1)}_{1} + (1, 1)^{(2, -2)}_{-1} + (1, 1)^{(2, -2)}_{1} + (1, 2)^{(-1, -1)}_{-1} + (1, 2)^{(-1, -1)}_{1} + (1, 1)^{(4, 0)}_{0} + (1, 1)^{(-4, 0)}_{0} + (q + 2, 1)^{(0, 2)}_{0} + (q + 2, 1)^{(2, 0)}_{0} + (q + 2, 2)^{(0, -2)}_{1} + (q + 2, 2)^{(2, -2)}_{1}.
$$

Again, from the content it is obvious that the 1 and $q + 2$ vector multiplets enjoy a different status. As we shall see in section III the vector multiplets of this theory follow from two different terms appearing in the product of the Left and Right Yang-Mills factors, which implies that this *1st enhancement* will happen before squaring.

3. Magic

A 1st enhancement analogous to the previous one occurs also for \((q, P, \hat{P}) = (n, 1, 0)\) where \(n = \dim \mathbb{A} = 1, 2, 4, 8,\) for \(\mathbb{A} = \mathbb{R}, \mathbb{C}, \mathbb{H}, \mathbb{O}\) respectively, which implies that \(r = 2n.\) In these cases there is an accidental 2nd enhancement due to the maximal embedding \([\text{Str}_0(\mathbb{A}^c)]_c \supset SO(n + 2) \times S_n(1, 0) \times U(1)''\) such that the resulting coset is:

\[
\frac{G}{H} \times SU(2) = \frac{\text{Conf}(\mathbb{A}_c)}{[\text{Str}_0(\mathbb{A}_c)]_c \times U(1)'} \times SU(2) / SU(2),
\]

where \(\mathbb{A}_c \cong \mathbb{C} \otimes \mathbb{A},\) \(\mathbb{A}^c_3\) is the cubic Jordan algebra of \(3 \times 3\) Hermitian matrices over \(\mathbb{A}\) and \(\mathbb{A}_c^c \cong \mathbb{C} \otimes \mathbb{A}_c^c\) its complexification, \(\text{Conf}(\mathbb{A})\) is the conformal group of the cubic Jordan algebra \(\mathbb{A},\) \(\text{Str}_0(\mathbb{A})\) the reduced structure group and \([G]\) denotes the compact real form of the complexified group \(G.\) The content is \(G = \mathbb{G}_2 \oplus dV_2\) where \(d = 1 + n + 2 + 2n = 3(n + 1)\), which under

\[
U(1)'^t \times H \times SU(2) = U(1)' \times [\text{Str}_0(\mathbb{A}_c)]_c \times SU(2) \times U(1)
\]

transforms as

\[
\\begin{align*}
(1, 1)^0_4 &+ (1, 1)^0_1 \\
(1, 2)^3_3 &+ (1, 2)^-3 \\
(1, 1)^0_{-2} &+ (1, 1)^6_2 + (\overline{d}, 1)^2_2 + (d, 1)^2_2 \\
(\overline{d}, 2)^1_{-1} &+ (d, 2)^1_1 \\
(\overline{d}, 1)^4_0 &+ (d, 1)^-4_0,
\end{align*}
\]

where the representations \(d\) are given in Table III.

| \(n\) | \(\text{Conf}(\mathbb{A}_c)\) | \([\text{Str}_0(\mathbb{A}_c)]_c\) | \(d\) | \(SO(n + 2) \times S_n(1, 0)\) | \(r\) |

| 4 | \(SO^*(12)\) | \(SU(6)\) | 15 | \((SU(4) \times SP(1))\) | \((4, 2)\) |
| 8 | \(E_7(-25)\) | \(E_6\) | 27 | \(SO(10)\) | 16 |

TABLE III. Groups and representations appearing the in the 2nd enhancement for the magic supergravities.

The 2nd enhancement is possible because in all four cases there is a representation \(d,\) which under \([\text{Str}_0(\mathbb{A}_c)]_c \supset SO(n + 2) \times S_n(1, 0) \times U(1)''\) branches to:

\[
d \rightarrow (1, 1)^{-4} + (q + 2, 1)^2 + r^{-1},
\]

where the groups and corresponding representations are given in Table III.

Note, there is a unified description of the 2nd enhancement for magic theories: they lie in the “complexified projective planes” \((\mathbb{C} \otimes \mathbb{A})\mathbb{P}^2.\) Namely, the enhancement terms lie in the compact symmetric coset

\[
\frac{[\text{Str}_0(\mathbb{A}_c)]_c}{[\text{Str}_0(\mathbb{A} \oplus \mathbb{A}_c)]_c \times S_n(1, 0)},
\]

where \([\text{Str}_0(\mathbb{C} \oplus \mathbb{A}_c)]_c \times S_n(1, 0) = SO(q + 2) \times S_n(1, 0) \times U(1)''\) and \(S_n(1, 0) = S_q(0, 1) = \text{Id}, U(1), \text{Sp}(1), \text{Id}\) for \(q = 1, 2, 4, 8\) (or, equivalently, \(S_q(0, 1) = S_q(0, 1) = \text{tri}(\mathbb{A})/\text{so}(\mathbb{A}),\) where \(\text{tri}(\mathbb{A})\) and \(\text{so}(\mathbb{A})\) respectively denote the tridality and orthogonal symmetries of \(\mathbb{A} = \mathbb{R}, \mathbb{C}, \mathbb{H}, \mathbb{O}\) [54]) and the symmetric embedding \([\text{Str}_0(\mathbb{C} \oplus \mathbb{A}_c)]_c \times S_n(1, 0) \subset [\text{Str}_0(\mathbb{A}_c)]_c\) follows from the maximal Jordan algebra embedding, \(\mathbb{C} \oplus \mathbb{A}_c \subset \mathbb{A}_c^c.\) The tangent space of (11) can be represented as \(\mathbb{A}_c \oplus \mathbb{A}_c,\) where the summands carry equal and opposite \(U(1)''\)
charges (specifically 3 vs. −3). Namely, they are a pair of chiral spinors in \( D = q + 2 \) critical dimensions; for \( q = 1 \) there is no chiral splitting. Note, these groups are the compact analogs of the \( SO(1,q + 1) \times S_n(1,0) \) U-duality groups of the corresponding \( D = 6 \) magic supergravity theories and the \( U(1)'' \) appearing in the stabilizer of (11) is the compact version of the Kaluza-Klein \( SO(1,1) \) of the compactification from \( D = 6 \) to \( D = 5 \).

The vector multiplets \( 1, q + 2 \) and \( r \) come from three different terms appearing in the product of the Left and Right Yang-Mills factors, which implies that the 2nd enhancement only appears after squaring. Hence, for the purpose of matching the content to that obtained from the Left and Right Yang-Mills factors, we should first decompose under \( U(1)^{st} \times SO(n + 2) \times S_n(1,0) \times SU(2) \times U(1)' \times U(1)'' \):

\[
(\mathbf{1,} \mathbf{1})_{-1}^{(1,1)} + (\mathbf{1,} \mathbf{1})_{4}^{(1,1)} + (\mathbf{1,} \mathbf{2})_{-3}^{(3,0)} + (\mathbf{1,} \mathbf{2})_{3}^{(-3,0)}
\]

\[
(\mathbf{1,} \mathbf{1})_{-2}^{(6,0)} + (\mathbf{1,} \mathbf{1})_{2}^{(-6,0)} + (\mathbf{1,} \mathbf{1})_{-2}^{(-2,4)} + (\mathbf{1,} \mathbf{1})_{2}^{(2,-4)} + (\mathbf{q + 2,} \mathbf{1})_{-2}^{(-2,-2)} + (\mathbf{q + 2,} \mathbf{1})_{2}^{(2,2)}
\]

\[
(\mathbf{r,} \mathbf{1})_{-2}^{(-2,1)} + (\mathbf{r,} \mathbf{1})_{2}^{(2,-1)}
\]

\[
(\mathbf{1,} \mathbf{1,} \mathbf{2})_{-1}^{(1,4)} + (\mathbf{1,} \mathbf{1,} \mathbf{2})_{1}^{(-1,-4)} + (\mathbf{q + 2,} \mathbf{1,} \mathbf{2})_{-1}^{(-1,-2)} + (\mathbf{q + 2,} \mathbf{1,} \mathbf{2})_{1}^{(-1,2)}
\]

\[
(\mathbf{r,} \mathbf{2})_{-1}^{(1,1)} + (\mathbf{r,} \mathbf{2})_{1}^{(-1,-1)}
\]

\[
(\mathbf{1,} \mathbf{1,} \mathbf{1})_{0}^{(4,4)} + (\mathbf{1,} \mathbf{1,} \mathbf{1})_{0}^{(-4,-4)} + (\mathbf{q + 2,} \mathbf{1,} \mathbf{1})_{0}^{(-4,-2)} + (\mathbf{q + 2,} \mathbf{1,} \mathbf{1})_{0}^{(-4,2)}
\]

\[
(\mathbf{r,} \mathbf{1})_{0}^{(4,1)} + (\mathbf{r,} \mathbf{1})_{0}^{(-4,-1)}
\]

\[
\text{(12)}
\]

\[
4. \text{ Minimally coupled}
\]

The three classes of theories summarised above relied on the method of classifying SK manifolds through their dimensional reduction from \( D = 5 \) and are thus unified in their description. The minimally coupled supergravities, however, do not in general admit an oxidation to \( D = 5 \) and so stand on their own, not fitting the general analysis of the previous three classes. Note, however, the Yang-Mills squared description unifies them all, as we shall see. The minimally coupled symmetric scalar coset is:

\[
G / H = SU(2) / U(1) \times SU(2) / U(1) = SU(1, P + 1) \times U(1) \times SU(2) / U(1) \times SU(2)
\]

which is isomorphic to the hyperbolic projective space \( \mathbb{CP}^{P+1} \). For more details, see Table 9 of [49] and the associated comments. Their content is given by \( G_2 \oplus (P + 1) \mathbb{V}_2 \), which under

\[
U(1)^{st} \times SU(2) = U(1)^{st} \times SU(P + 1) \times SU(2) \times U(1)_{min} \times U(1)
\]

transforms as

\[
(\mathbf{1,} \mathbf{1})_{-4}^{(0,0)} + (\mathbf{1,} \mathbf{1})_{4}^{(0,0)} + (\mathbf{1,} \mathbf{2})_{-3}^{(P+1,1)} + (\mathbf{1,} \mathbf{2})_{3}^{(-P-1,-1)} + (\mathbf{1,} \mathbf{1})_{-2}^{(2P+2,2)} + (\mathbf{1,} \mathbf{1})_{2}^{(-2P-2,-2)} + (\mathbf{P + 1,} \mathbf{1})_{-2}^{(-2,-2)} + (\mathbf{P + 1,} \mathbf{1})_{2}^{(-2,2)} + (\mathbf{P + 1,} \mathbf{2})_{-1}^{(P+3,-1)} + (\mathbf{P + 1,} \mathbf{2})_{1}^{(-3,-3,1)} + (\mathbf{P + 1,} \mathbf{1})_{0}^{(2P+4,0)} + (\mathbf{P + 1,} \mathbf{1})_{0}^{(-2P-4,0)}.
\]

Anticipating the Yang-Mills squared construction, the 1 and \( P \) vector multiplets will necessarily come from two distinct terms in the product. Consequently, in order to match the content with that obtained by squaring we need to further decompose \( SU(P + 1) \supset SU(P) \times U(1)_P \). Under the resulting

\[
U(1)^{st} \times SU(P) \times SU(2) \times U(1)_{min} \times U(1) \times U(1)_P
\]

transforms as

\[
(\mathbf{1,} \mathbf{1})_{-4}^{(0,0)} + (\mathbf{1,} \mathbf{1})_{4}^{(0,0)} + (\mathbf{1,} \mathbf{2})_{-3}^{(P+1,1)} + (\mathbf{1,} \mathbf{2})_{3}^{(-P-1,-1)} + (\mathbf{1,} \mathbf{1})_{-2}^{(2P+2,2)} + (\mathbf{1,} \mathbf{1})_{2}^{(-2P-2,-2)} + (\mathbf{P + 1,} \mathbf{1})_{-2}^{(-2,-2)} + (\mathbf{P + 1,} \mathbf{1})_{2}^{(-2,2)} + (\mathbf{P + 1,} \mathbf{2})_{-1}^{(P+3,-1)} + (\mathbf{P + 1,} \mathbf{2})_{1}^{(-3,-3,1)} + (\mathbf{P + 1,} \mathbf{1})_{0}^{(2P+4,0)} + (\mathbf{P + 1,} \mathbf{1})_{0}^{(-2P-4,0)}.
\]
the content transforms as:

\[(1, 1)^{(0,0,0)} + (1, 1)^{(0,0,0)}\]

\[(1, 2)^{(-P+1,1,0)} + (1, 2)^{(-P-1,-1,0)}\]

\[(1, 1)^{(2P+2,2,0)} + (1, 1)^{(-2P-2,-2,0)} + (1, 1)^{(2,-2,P)} + (1, 1)^{(-2,-2,P)} + (P, 1)^{(2,-2,1)} + (\overline{P}, 1)^{(-2,-2,-1)}\]

\[(1, 2)^{(P+3,-1,-1)} + (1, 2)^{(-P+3,1,1)} + (P, 2)^{(P+3,-1,1)} + (\overline{P}, 2)^{(-P+3,1,-1)}\]

\[(1, 1)^{(2P+4,0,-P)} + (1, 1)^{(-2P-4,0,P)} + (P, 1)^{(2P+4,0,1)} + (\overline{P}, 1)^{(-2P-4,0,-1)}\]

Naively, this can be regarded as the extension of Table II to \((q, P, \dot{P}) = (-2, P, 0)\) with \(r = P^{-1} + \overline{P}^3\) of \(U(P)\) [49].

5. \(T^3\) model

Like the generic Jordan and magic supergravities, the \(T^3\) model can be constructed using a cubic Jordan algebra, namely \(J_3 \cong \mathbb{R}\). However, it does not strictly sit in the generic Jordan sequence, rather it should be considered as the “symmetrization” of the \(q = 0\) generic Jordan supergravity (otherwise known as the STU model [55]). This is reflected by the fact that it follows from the dimensional reduction of “pure” \(N = 2, D = 5\) supergravity. The \(T^3\) scalar coset is:

\[\frac{G}{H} / SU(2) = SU(1,1) / U(1)_T \times SU(2) / SU(2)\]  \quad (18)

The content \(G_2 \oplus V_2\) transforms under

\[U(1)^{st} \times H \times SU(2) = U(1)^{st} \times SU(2) \times U(1)_T\]  \quad (19)

as

\[1^0_{-4} + 1^0_4\]

\[2^1_{-3} + 2^1_3\]

\[1^2_{-2} + 1^2_2\]

\[1^6_{-2} + 1^6_2\]

\[2^5_{-1} + 2^5_1\]

\[1^4_0 + 1^4_3\]

It is not possible to generate the \(T^3\) model from Yang-Mills squared, at least not straightforwardly, although the content and representations presented above can be reproduced by the product of \(N_L = 2\) and \(N_R = 0\) Yang-Mills theories. We will address these two comments properly in section III C 1.

B. Hyper multiplets

Here we consider the inclusion of hyper multiplets. The coset manifold parametrised by the hyper scalars must be quaternionic [53, 56, 57]. In the previous subsection the \(SU(2)\) R-symmetry was included as an additional factor commuting with isometries of the SK scalar manifolds. When hyper multiplets are included this \(SU(2)\) factor is absorbed by the Q manifold of the hyper scalars. Specifically, it becomes part of the Q manifold holonomy group, which for homogeneous manifolds is in turn part of the isotropy group.

1. Non-symmetric

The non-symmetric hyper scalar Q manifold is the c-map [49] of the non-symmetric SK manifold given in (2),

\[G / H = SO(1,1) \times \frac{SO(q + 3,3)}{SO(q + 3) \times SU(2)_{ns}} \times \frac{S_q(P, \dot{P})}{S_q(P, P)} \times (\text{spin, def})^1 \times (q + 6, 1)^2\]  \quad (22)
Note, the \((q, P, \dot{P})\) used here are independent of those appearing in the SK manifold \((2)\). The additional content is \((q + 4 + s/2)H_2\), which under

\[
U(1)^st \times \mathcal{H} = U(1)^st \times SO(q + 3) \times S_q(P, \dot{P}) \times SU(2)_{ns}.
\]

transforms as

\[
(q + 3, 1, 2)_{-1} + (q + 3, 1, 2)_1 \quad + \quad (1, 1, 2)_{-1} + (1, 1, 2)_1 \quad + \quad (s, 1)_{-1} + (s, 1)_1
\]

\[
(q + 3, 1, 3)_0 + (q + 3, 1, 1)_0 \quad + \quad (1, 1, 3)_0 + (1, 1, 1)_0 \quad + \quad (s, 2)_0,
\]

where \(s\) is a not necessarily irreducible representation of \(SO(q + 3) \times S_q(P, \dot{P})\), as given in Table IV, of dimension \(s = 2^{[(q+3)/2]} \dim \text{def}\).

\[
\begin{array}{cccc}
q & SO(q + 3) & S_q(P, \dot{P}) & s \\
-2 & -//- & U(P) & P_{-x} + P_x \\
-1 & U(1)^{st} & SO(P) & P_{-x} + P_x \\
0 & SU(2) & SO(P) \times SO(\dot{P}) & (2P) + (2\dot{P}) \\
1 & SU(2)^2 & SO(P) & (2P) + (2\dot{P}) \\
2 & Sp(2) & U(P) & (4P)_{-x} + (4\dot{P})_x \\
3 & SU(4) & Sp(P) & (2P) + (2\dot{P}) \\
4 & SO(7) & Sp(P) \times Sp(\dot{P}) & (8P) + (8\dot{P}) \\
5 & SO(8) & Sp(P) & (8P) + (8\dot{P}) \\
6 & SO(9) & U(P) & (16P)_{-x} + (16\dot{P})_x \\
7 & SO(10) & SO(P) & (16P) + (16\dot{P})_x \\
8 & SO(11) & SO(P) \times SO(\dot{P}) & (32P) + (32\dot{P}) \\
\end{array}
\]

TABLE IV. Groups and representations appearing in \((22)\) and \((24)\). Note, the \(q = -2\) case corresponds to the c-map of the minimally coupled vector multiplet series \((13)\), see Table 9 of [49]. Again, \(S_q(P, \dot{P})\) enjoys the standard mod 8 Bott periodic pattern in \(q\).

\[\text{2. Generic Jordan}\]

As for the vector multiplet sector, there are particular choices of \((q, P, \dot{P})\) for which the non-reductive terms appearing in \((22)\) carry representations that allow for the so-called 1st enhancement \(SO(1, 1) \times SO(q + 3, 3) \subset SO(q + 4, 4)\). In this case the representations \(s\) enhance to \(\mathfrak{t}\) as given in Table V, and the resulting coset spaces are symmetric. The simplest example is the c-map of the generic Jordan series \((5)\), which occurs for \((q, P, \dot{P}) = (q, 0, 0)\), implying that \(s = 0\), or alternatively, for \((q, P, \dot{P}) = (0, P, 0)\) or \((0, 0, P)\) [53]. The resulting symmetric hyper scalar coset is given by,

\[
\frac{G}{\mathcal{H}} = \frac{SO(q + 4, 4)}{SO(q + 4) \times SU(2) \times SU(2)'}.
\]

The additional content is \((q + 4)H_2\) which under

\[
U(1)^{st} \times \mathcal{H} = U(1)^{st} \times SO(q + 4) \times SU(2) \times SU(2)'
\]

transforms as,

\[
(q + 4, 1, 2)_{-1} + (q + 4, 2, 2)_0 + (q + 4, 1, 2)_1.
\]

As we shall see in section III this 1st enhancement will happen before squaring, in the sense that the Right Yang-Mills theory itself has a global \(SO(q + 4)\) symmetry that becomes the \(SO(q + 4)\) of \((25)\).
are a pair of chiral spinors in terms lie in the compact symmetric coset for magic theories: they lie in the “quaternionified projective planes” (32) can be represented as

\[
\mathcal{G} = \frac{QConf(3^3)}{[Conf(3^3)]_c \times SU(2)},
\]

where \(QConf(3)\) is the quasi-conformal group of the Jordan algebra \(3\). The additional content is \((f/2)H_2\) where \(f = 2(3n + 4)\), which under

\[
U(1)^{st} \times H = U(1)^{st} \times [Conf(3^3)]_c \times SU(2)
\]

transforms as

\[
(f, 1)_1 + (f, 2)_0 + (f, 1)_{-1}.
\]

The 2nd enhancement is possible because in all four cases there is a symplectic representation \(f\), which under \([Conf(3^3)]_c \supset SO(n + 4) \times S_n(1, 0) \times SU(2)\) decomposes as,

\[
f \mapsto (q + 4, 1, 2) + (t, 1),
\]

where \(f\) and \(t\) are given in Table VI. As we will see in section III the hyper multiplets come exclusively from the product of Left factor half-hyper multiplets with Right factor scalars, so these enhancements happen before squaring.

Note, as for the magic vector multiplet case given in section II A 3, there is a unified description of the 2nd enhancement for magic theories: they lie in the “quaternionified projective planes” \((H \otimes A)P^2\). Namely, the enhancement terms lie in the compact symmetric coset

\[
[Conf(3^3)]_c/[Conf(C \oplus 3^2)]_c \times S_n(1, 0),
\]

where \([Conf(C \oplus 3^2)]_c \times S_n(1, 0) = SO(q + 4) \times SU(2') \times S_n(1, 0)\). The symmetric embedding \([Conf(C \oplus 3^2)]_c \times S_n(1, 0) \subset [Conf(3^3)]_c\) follows from the maximal Jordan algebra embedding, \(C \oplus 3^2 \subset 3^3\). The tangent space of (32) can be represented as \(H \otimes A \oplus H \otimes A\), where the summands transform as a doublet under \(SU(2)\). Namely, they are a pair of chiral spinors in \(D = q + 4\) dimensions; for \(q = 1\) there is no chiral splitting.

### TABLE V. Groups and representations for hyper scalar Q manifolds with the 1st enhancement \(s \rightarrow t\).

| \(q\) | \(SO(q + 4)\) | \(S_q(P, \bar{P})\) | \(t\) | \(t(q, P, \bar{P})\) |
|---|---|---|---|---|
| -3 | \(-3\) / / / | \(Sp(P)\) | \(2P\) | \(2P\) |
| -2 | \(U(1)\) | \(U(P)\) | \(2\) \(P\) \(_{(+, a)} + \bar{P}_{(-, a)}\) | \(2P\) |
| -1 | \(SU(2)\) | \(SO(P)\) | \(2P\) | \(2P\) |
| 0 | \(SU(2)^2\) | \(SO(P) \times SO(\bar{P})\) | \((2, 1, P, 1) + (1, 2, 1, \bar{P})\) | \(2P + 2\bar{P}\) |
| 1 | \(Sp(2)\) | \(SO(P)\) | \(4\) \(P\) | \(4P\) |
| 2 | \(SU(4)\) | \(U(P)\) | \((8, 2P) + (8, \bar{P})\) | \(16P + 16\bar{P}\) |
| 3 | \(SO(7)\) | \(Sp(P)\) | \((16, 2P)\) | \(32P\) |
| 4 | \(SO(8)\) | \(Sp(P) \times Sp(\bar{P})\) | \((8, 2P) + (8, \bar{P})\) | \(32P\) |
| 5 | \(SO(9)\) | \(Sp(P)\) | \((16, 2P)\) | \(32P\) |
| 6 | \(SO(10)\) | \(U(P)\) | \((16, \bar{P}) + (\bar{P}, P)\) | \(32P\) |
| 7 | \(SO(11)\) | \(SO(P)\) | \((32, P)\) | \(32P + 32\bar{P}\) |
| 8 | \(SO(12)\) | \(SO(P) \times SO(\bar{P})\) | \((32, P, 1) + (32, 1, \bar{P})\) | \(32P + 32\bar{P}\) |
For the above cases the quaternionic manifolds of the hyper sector are insensitive to dimensional reduction, and therefore are the same in $D = 3, 4, 5, 6$. These spaces can be constructed by composing the r-map and c-map into a map (termed the q-map in mathematical literature, cfr. e.g. [58]) from real special homogeneous manifolds. By contrast, for the addition of hyper multiplets to the minimally coupled model of section II A 4 there is no real special homogeneous starting point (i.e. there is no r-map and hence no q-map). However the scalar coset,

$$\frac{G}{H} = \frac{SU(P,2)}{U(P) \times SU(2)},$$

(33)

is given by the c-map of the SK minimally coupled series (13), as one would anticipate. The additional content is $PH_2$, which under

$$U(1)^{st} \times H = U(1)^{st} \times U(P) \times SU(2)$$

(34)

transforms as

$$(P, 1)^{-1}_{-1} + (P, 1)^{-1}_{+1} + (P, 2)^{-1}_{0} + (P, 2)^{1}_{0} + (P, 1)^{-1}_{0} + (P, 1)^{1}_{0}.$$  

(35)

This can be regarded as the $(q, P, \dot{P}) = (-4, P, 0)$ extension of Table V, with $t = P^{-1} + \dot{P}$ of $U(P)$, as given in Table 9 of [49].

5. Projective quaternionic

A second possibility for minimally coupled hyper multiplets is given by

$$\frac{G}{H} = \frac{Sp(P,1)}{Sp(P) \times SU(2)}.$$  

(36)

These are projective quaternionic symmetric spaces given by $q = -3$ of Table V (also cfr. table 9 of [49]). Note, they are not in the c-map image of any (projective) special Kähler manifold and in this sense they are distinguished. The additional content is $PH_2$, which under

$$U(1)^{st} \times H = U(1)^{st} \times Sp(P) \times SU(2)$$

(37)

transforms as

$$(2P, 1)^{-1}_{-1} + (2P, 2)^{1}_{0} + (2P, 1)^{1}_{1}.$$  

(38)

This can be regarded as the $(q, P, \dot{P}) = (-3, P, 0)$ entry of Table V with $t = 2P$ of $Sp(P)$. 

| n | $QConf(JA^3)$ | $[Conf(JAC^3)]_c$ | $f$ | $SO(n + 4) \times S_u(1,0)$ | $t$ |
|---|---|---|---|---|---|
| 1 | $F_{(4(4))}$ | $Sp(3)$ | 14' | $Sp(2)$ | 4 |
| 2 | $E_6(3)$ | $SU(6)$ | 20 | $SU(4) \times U(1)$ | 4 - x + 4 x |
| 4 | $E_7(-5)$ | $SO(12)$ | 32 | $SO(8) \times Sp(1)$ | (8, 2) or (8, 2) |
| 8 | $E_8(-24)$ | $E_7$ | 56 | $SO(12)$ | 32 |

TABLE VI. The $H$ representations $f$ carried by the magic hyper scalars and the representations $t$ appearing in the breaking $f \rightarrow (q + 4, 1, 2) + (t, 1)$ under $SO(n + 4) \times S_u(1,0) \times SU(2)' \subset [Conf(JAC^3)]_c$. 

4. Minimally coupled
6. Exceptional $T^3$ model

The final case is given by the inclusion of hyper multiplets in the $T^3$ model. The coset is exceptional,

$$\frac{G}{H} = \frac{G_2(2)}{SU(2)_E \times SU(2)}.$$  \hspace{1cm} (39)

and is the c-map of (18) or the q-map of a point, reflecting the fact that dimensionally reducing pure $D = 5$ supergravity to $D = 3$ yields a scalar coset given by (39) once the 1-form potentials have been dualised to scalars. The additional content is $2H_2$, which under $U(1)^a \times H = U(1)^a \times SU(2)_E \times SU(2)$ transforms as,

$$(4, 1)_{-1} + (4, 2)_0 + (4, 1)_1.$$  \hspace{1cm} (40)

III. SQUARING

A. General principles

The field content generated by all products of Left and Right multiplets (excluding those generating gravitino multiplets) are given in Table VII. These are deduced using the tensor product of asymptotic on-shell helicity states, which we denote by $\otimes$. Of course, this does not fix the couplings or symmetries of the corresponding theory (unless they are fixed by supersymmetry). However, following [1] we can use the convolutive tensor product, $\circ$, of Left and Right spacetime fields to deduce the possible symmetries and hence couplings of the resulting theory. For Left and Right multiplets $L, R$, the product is defined by

$$L \circ R := L^\Sigma \Phi_{\Sigma \bar{\Sigma}} \ast R^{\bar{\Sigma}},$$  \hspace{1cm} (41)

where

$$[f \ast g](x) = \int d^D y f(y)g(x-y)$$  \hspace{1cm} (42)

for arbitrary spacetime fields $f, g$. The convolution reflects the fact that the amplitude relations are multiplicative in momentum space. It turns out to be essential for reproducing the local symmetries of (super)gravity from those of the two (super) Yang-Mills factors to linear order [1, 4, 5]. The spectator field $\Phi_{\Sigma \bar{\Sigma}}$ allows for arbitrary and independent $G_L$ and $G_R$ at the level of spacetime fields. The indices $\Sigma, \bar{\Sigma}$ run over the representations carried by the Left and Right multiplets under the Left and Right gauge groups $G_L$ and $G_R$. The spectator takes a block-diagonal form,

$$\Phi = \begin{pmatrix} \Phi_{A \bar{A}} & 0 \\ 0 & \Phi_{\alpha \bar{\alpha}} \end{pmatrix},$$  \hspace{1cm} (43)

where $A, \bar{A}$ are adjoint\(^2\) and $\alpha, \bar{\alpha}$ are “fundamental”\(^3\) indices of $G_L$ and $G_R$, respectively. This ensures the fact that adjoint representations only double-copy with adjoint representations [5, 22]. As discussed in detail in [1, 3–5, 41, 42] this product allows us to reconstruct the symmetries of the resulting supergravity theory (under the assumption that the scalar coset manifold is homogeneous) in terms of its Yang-Mills-matter factors and we apply these same principles in the subsequent analysis. Note, the product of the global symmetries of the two factors yields a subset of the gravitational global symmetries, which are enhanced to the full set of generically non-compact global symmetries as described in appendix A.

B. The gauge theory factors

Here we summarise the Left and Right Yang-Mills-matter theories used subsequently to generate the supergravity theories described in the previous sections.

\(^2\) Note, the bi-adjoint scalar field $\Phi_{A \bar{A}}$ plays a crucial role in the Yang-Mills squared construction of classical (supersymmetric) single- and multi-centre black hole solutions [6, 7] and also appears by very close analogy in the non-perturbative double-copy construction of Kerr-Schild solutions [35–38], although the precise relationship between the two pictures remains an intriguing open question.

\(^3\) Here we use “fundamental” to mean any (not necessarily irreducible) representations other than the adjoint.
under which the various fields transform as follows:

| L ⊗ R       | Result                        |
|-------------|-------------------------------|
| C₁ ⊗ λ     | V₁ ⊕ C₁                       |
| C₁ ⊗ C₁    | V₂ ⊕ H₂                       |
| C₂ ⊗ λ     | V₂                           |
| C₂ ⊗ C₁    | V₃                           |
| C₂ ⊗ H₂    | V₄                           |
| H₂ ⊗ λ     | 2V₂                          |
| H₂ ⊗ C₁    | 2V₃                          |
| H₂ ⊗ H₂    | 4V₄                          |

| L ⊗ R       | Result                        |
|-------------|-------------------------------|
| V₁ ⊗ A     | G₁ ⊕ C₁                       |
| V₁ ⊗ V₁    | G₂ ⊕ H₂                       |
| V₂ ⊗ A     | G₂ ⊕ V₂                       |
| V₂ ⊗ V₁    | G₃ ⊕ V₃                       |
| V₂ ⊗ V₂    | G₄ ⊕ 2V₄                     |
| V₄ ⊗ A     | G₄                           |
| V₄ ⊗ V₁    | G₅                           |
| V₄ ⊗ V₂    | G₆                           |
| V₄ ⊗ V₄    | G₈                           |

TABLE VII. The content resulting from the product of the on-shell helicity states of Left and Right multiplets, as summarised in Table I.

1. The Left $\mathcal{N}_L = 2$ gauge theory

The Left theory consists of one $\mathcal{N} = 2$ vector multiplet $V_2^A$ and one half-hyper multiplet $C_2^a$, which carries a pseudoreal fundamental representation of the Left gauge group $G_L$. Note, we use $A$ and $a$ to distinguish fields carrying adjoint and fundamental representations, respectively, of the gauge group. The spacetime, global and gauge symmetries are given by

$$U(1)^{st}_L \times SU(2)_L \times U(1)_L \times G_L,$$

under which the multiplets transform as follows:

$$V_2^A : \left[1^0_{-2} + 1^0_{2} + 2^1_{-1} + 2^2_1 + 1^0_{0} + 1^2_{-2}\right]^A,$$

$$C_2^a : \left[1^0_{-1} + 1^1_{1} + 2^0_0\right]^a,$$

where the superscripts denote the R-symmetry $U(1)_L$ charges $C_L$.

2. The Right $\mathcal{N}_R = 0$ gauge theory

The Right theory consists of one $\mathcal{N} = 0$ vector potential $A^A_\mu$ and $q + 2$ scalars $\phi^A$ in the adjoint of the Right gauge group $G_R$ and $r$ Majorana spinors $\lambda^a$ and $2(q' + 4) + t$ scalars $\Phi^a, \varphi^a$ in a pseudoreal fundamental representation of $G_R$. The spacetime, global and gauge symmetries are given by

$$U(1)^{st}_R \times SO(q + 2) \times F_q \times SO(q' + 4) \times F_{q'} \times SU(2)_R \times G_R,$$

under which the various fields transform as follows:

$$A^A_\mu : \left[(1, 1; 1, 1, 1)_{-2} + (1, 1; 1, 1, 1)_2\right]^A,$$

$$(q + 2)\phi^A : \left[(q + 2, 1; 1, 1, 1)_0\right]^A,$$

$$(r)\lambda^a : \left[(r; 1, 1, 1)_{-1} + (\bar{r}; 1, 1, 1)_1\right]^a,$$

$$2(q' + 4)\Phi^a : \left[(1, 1; q' + 4, 1, 2)_0\right]^a,$$

$$(t)\varphi^a : \left[(1, 1; t, 1)_0\right]^a.$$

---

4 We also always require that the adjoint of the gauge group is included in the symmetric tensor product of the pseudoreal fundamental.
The groups \( F_q \) and \( F_{-q} \) will be determined by the reality conditions. The fermion \( \lambda \) representations \( r = (\text{spin}_{q+2}, \text{def}_{F_q}) \) are given by the spinor of \( SO(q + 2) \) and the defining representation of \( F_q \). The overall reality conditions imply that for \( q \geq -1 \) the flavour group is \( F_q = Sp(P, \bar{P}) \). For \( q = -2 \) the group \( SO(q + 2) \) disappears and the only possible flavour group consistent with overall reality is \( F_{-2} = U(P)_F = SU(P)_F \times U(1)_F \), where the \( U(1)_F \) charges carried by the fields will be denoted \( C_F \). The scalars \( \varphi \) are in the spinor of \( SO(q' + 4) \) and defining of \( F_{q'} \), \( t = (\text{spin}_{q'+4}, \text{def}_{F_{q'}}) \). The overall reality conditions imply that for \( q' \geq -3 \) the flavour group is \( F_{q'} = Sp(P', \bar{P}') \). For \( q' = -4 \) there are two options consistent with overall reality given by \( F_{-4} = Sp(P) \) or \( U(P)_F = SU(P)_F \times U(1)_F \), where the \( U(1)_F \) charges carried by the fields will be denoted \( C_F \).

For the Right theory fields (see Table X for a summary of the various spacetime, global and gauge indices),

\[
A^A_m, \quad \phi^A_m, \quad \lambda^a_I, \quad \Phi^a_M, \quad \varphi^m_X, \quad \varphi^m_i,
\]

the most general Lagrangian consistent with the symmetries (47) is given by,

\[
\mathcal{L} = -\frac{1}{4} F^\mu\nu A F^{\mu\nu} + \frac{1}{2} D_\mu \phi^A_m D^\mu \phi^A_m - \frac{1}{2} \lambda^a_I (\gamma^\mu) \alpha \beta D_\mu \lambda_{a\beta}^I + \frac{1}{2} D_\mu \Phi^a_M D^\mu \Phi^b_M \delta_{ab} \Omega_{ab} + \frac{1}{2} D_\mu \varphi^a_X D^\mu \varphi^b_X \chi_{ab} + \Phi^a_M \Phi^b_N \Phi^c_P \Phi^d_Q p_{abcd} + \varphi^X_i \varphi^Y_j \varphi^Z_k \varphi^W_l p_{XYZWabcd} + \Phi^a_M \Phi^b_N \varphi^X_i \varphi^Y_j \varphi^Z_i \varphi^W_k p_{XYZWabcd} + \varphi^m_X \varphi^m_i \varphi^m_j \varphi^m_k p_{XMNabcd},
\]

where the relative coefficients of the fields generating the vector multiplet sector \( (A, \phi, \lambda) \) are fixed by regarding it as the dimensional reduction of a \( D = q + 6 \) Yang-Mills theory coupled to \( P \) and \( \bar{P} \) spinors. The various invariant tensors are given explicitly by,

\[
P_{abcd} = h_1 T_{(ab)(cd)} M_{(ab)(cd)} + h_2 T_{[ab][cd]} M_{[ab][cd]}, \quad (55)
\]

\[
P_{XYZWabcd} = k_1 T_{(XY)(ZW)} M_{(ab)(cd)} + k_2 T_{[XY][ZW]} M_{[ab][cd]} + k_3 T_{(XY)(ZW)} M_{(ab)[cd]} + k_4 T_{[XY][ZW]} M_{[ab](cd)}, \quad (56)
\]

\[
P_{XYMNabcd} = l_1 \mathcal{R}_{(MN)X} M_{[ab][cd]} + l_2 \mathcal{R}_{(MN)X} M_{(ab)(cd)}, \quad (57)
\]

where the free parameters \( h_i, k_i, l_i \) are real and

\[
M_{(ab)(cd)} = (T^A)_{ab} (T^A)_{cd} = \tau (-3 f_{abcd}) + \Omega_{a(c} \Omega_{b)d)}, \quad (58)
\]

\[
M_{[ab][cd]} = \Omega_{ab} \Omega_{cd} - 2 \Omega_{a[c} \Omega_{b]d)}, \quad (59)
\]

\[
T_{(ab)(cd)} = \varepsilon_{a(c} \varepsilon_{d)b)}, \quad (60)
\]

\[
T_{[ab][cd]} = \varepsilon_{a[c} \varepsilon_{d)b]}, \quad (61)
\]

\[
T_{(XY)(ZW)} = S_{XY} S_{ZW} + 2 S_{Z(XS_Y)W} - 2 A_{Z(XA_Y)W}, \quad (62)
\]

\[
T_{[XY][ZW]} = A_{XY} A_{ZW} - 2 A_{Z[XA_Y]W} + 2 S_{Z[XS_Y]W}, \quad (63)
\]

\[
\mathcal{R}_{(MN)X} = \delta_{MN} \delta_X Y, \quad (64)
\]

\[
\mathcal{R}_{(MN)X} = (\Gamma_{MN})X Y, \quad (65)
\]

\[
S_{XY} S_{ZW} = \sum_p u_p (\Gamma_{M_1 ... M_p} (XY) (\Gamma_{M_1 ... M_p} (ZW), \quad (66)
\]

\[
A_{XY} A_{ZW} = \sum_p u_p (\Gamma_{M_1 ... M_p} (XY) (\Gamma_{M_1 ... M_p} (ZW), \quad (67)
\]

Here, \( \tau := 2 \dim G_R / (\dim^2 \text{fund}_{G_R} + \dim \text{fund}_{G_L}) \). Note, \( f_{(abcd)} \) is zero when the pseudoreal representation with index \( a \) is the defining of \( Sp(n) \). Examples of non-zero \( f_{(abcd)} \) are given by groups “of type \( E_7 \)”, for instance the 56 of \( E_7 \) [59–61].
TABLE VIII. A summary of the representations/indices appearing in (54). Note, (sgn) indicates the sign picked up on raising/lowering a pair of contracted indices of that type.

| Representation | $SO(1,3)_L^t$ | $SO(q + 2)$ | $F_q$ | $SO(q' + 4)$ | $F_{q'}$ | $SU(2)_R$ | $G_R$ |

C. The $|N_L = 2| \times |N_R = 0|$ product

The product of these two multiplets yields $N = 2$ supergravity coupled to $(1 + q + 2 + r)$ vector multiplets and $(q' + 4 + t/2)$ hyper multiplets, whose origin can be traced through,

$$Left \otimes Right = \left[ V^A_2 \otimes C_2^a \right] \otimes \left[ V^A \otimes (q + 2)\phi^A \otimes (r)\lambda^a \otimes 2(q' + 4)\Phi^a \otimes (t)\varphi^a \right]$$

$$= V^A_2 \otimes \left[ V^A \otimes (q + 2)\phi^A \right] \otimes C_2^a \otimes \left[ (r)\lambda^a \otimes 2(q' + 4)\Phi^a \otimes (t)\varphi^a \right]$$

$$= G_2 \otimes (1 + q + 2 + r)V_2 \oplus (q' + 4 + t/2)H_2.$$  

(68)

The supergravity theory inherits the global symmetries

$$U(1)^{st} \times H \times H = U(1)^{st} \times SO(q + 2) \times F_q \times SO(q' + 4) \times F_{q'} \times SU(2)_L \times SU(2)_R \times U(1)_L \times U(1)_R$$

(69)

directly from the two Yang-Mills factors. Noting that the vector multiplets carry non-trivial $SO(q+2) \times F_q$ representations, it is clear that the corresponding SK manifold $G/H$ will have $SO(q+2) \times F_q \subset H$. Similarly, the hyper multiplets carry non-trivial $SO(q' + 4) \times F_{q'} \times SU(2)_R$ representations and therefore $SO(q' + 4) \times F_{q'} \times SU(2)_L \times SU(2)_R \subset H$ will contribute to the Q manifold $G/H$.

Some more detailed comments on the various $U(1)$ factors appearing in (69) are in order. First, the $U(1)^{st}$ and $U(1)_-$ charges, denoted $C^{st}, C_-$ respectively, are given by the sum and difference of the Left and Right helicities $C_L^{st}, C_R^{st}$:

$$C^{st} = C_L^{st} + C_R^{st}$$

$$C_- = C_L^{st} - C_R^{st}.$$  

(70)

(71)

Unlike the symmetries inherited directly and independently from the gauge factors, the “helicity difference” $U(1)_-$ is not a priori a symmetry of the gravitational theory. However, as noted in [42] if the scalar manifold of the supergravity theory is symmetric the $U(1)_-$ symmetry is required by the squaring procedure. The simplest example is given by the product of two $\mathcal{N} = 0$ gauge potentials yielding axion-dilaton gravity, where the axion and dilaton parametrise $SL(2, \mathbb{R})/U(1)_-$.. Similarly, for maximal supersymmetry we have a global $SU(8)$ in $\mathcal{N} = 8$ supergravity, which factors into $U(1)_- \times SU(4)_L \times SU(4)_R$, where $SU(4)_{L/R}$ are the R-symmetries of the Left and Right $\mathcal{N} = 4$ Yang-Mills theories. On the other hand, if the scalar manifold is non-symmetric the $U(1)_-$ cannot be present. Note, this is reflected precisely by the double-copy construction:

5: if and only if the scalar manifold is symmetric the gravity amplitudes $U(1)_-$ invariant, as made evident by the examples constructed in [25].

To make this distinction clear in the present context we briefly illustrate the appearance of $U(1)_-$ in the symmetric generic Jordan sequence, where it is identified with the axio-dilatonic $U(1)_g$ in the stabilizer of (5). Note,

5 We thank Henrik Johansson for illuminating discussions regarding this point.
using the magic Jordan algebraic embedding $3^A \supset \mathbb{R} \oplus 3^B$, considered at the level of conformal symmetries, the second enhancement can be simultaneously made manifest at the expense of restricting to $q = 1, 2, 4, 8$. Adopting this starting point we then further branch the axio-dilatonic $SU(1, 1) \cong SL(2, \mathbb{R})$ to its non-compact Cartan, which generates the 5-grading:

\[
\text{Conf} \left( \mathbb{R}^3 \right) \supset \text{Conf} \left( \mathbb{R} \oplus 3^B \right) \times S_q \simeq SU(1, 1) \times SO(q + 2, 2) \times S_q \\
\supset SO(1, 1) \times SO(q + 2, 2) \times S_q;
\]  

(72)

\[
\text{Adj} = (1, \text{Adj}, 1) + (3, 1, 1) + (1, 1, \text{Adj}) + (2, \text{spin}, \text{def}) \\
= (\text{Adj}, 1)_0 + (1, 1, 1)_0 + (1, 1, \text{Adj})_0 + (1, 1)_{-2} + (\text{spin}, \text{def})_{-1} + (\text{spin}, \text{def})_{+1} + (1, 1)_{+2}.
\]  

(73)

One recognises the $G$ of homogeneous non-symmetric projective SK manifolds, given in (2), as the non-negatively graded part of (73), with the global $SU(2)$ factor omitted. However, for the symmetric case we also have the additional negative grade $(1, 1)_{-2}$ component, which when linearly composed with the $(1, 1)_{+2}$ component yields a maximal compact $U(1)$ subgroup of $SU(1, 1)$, identified with $U(1)_{+}$, generating the enhancement $SO(1, 1) \times SO(q + 2, 2) \rightarrow SU(1, 1) \times SO(q + 2, 2)$. For the magic cases of $q = 1, 2, 4, 8$ we see that (72) and (73) imply the further enhancement $SU(1, 1) \times SO(q + 2, 2) \times S_q \rightarrow \text{Conf} \left( \mathbb{R}^3 \right)$. In this sense, at least within the cubic models, the fact that the extra $U(1)$ is missing in the $T^3$ model can be traced back to the fact that the $T^3$ model does not contain (as a truncation) any element of the generic Jordan sequence.

1. Vector multiplets

In order to reproduce the SK manifolds of section II A, we consider those factors of (68) contributing to the vector multiplet sector, specifically:

\[
V_2^A \otimes \left[ V^A \oplus (q + 2) \phi^A \right] \otimes C_2^q \otimes (r) \lambda^a = G_2 \oplus (1 + q + 2 + r) V_2.
\]  

(74)

The resulting content $G_2 \oplus (1 + q + 2 + r) V_2$ carries non-trivial representations, inherited directly from the Left and Right Yang-Mills multiplets, under the factor of (69),

\[
(1, 1, 1)_{-4}^{(0,0)} + (1, 1, 1)_{4}^{(0,0)}
\]  

(76)

\[
(1, 1, 2)_{-3}^{(1,1)} + (1, 1, 2)_{4}^{(-1,-1)}
\]

\[
(1, 1, 1)_{-2}^{(2,2)} + (1, 1, 1)_{2}^{(-2,-2)} + (1, 1, 1)_{-2}^{(-2,2)} + (1, 1, 1)_{2}^{(2,-2)} + (q + 2, 1, 1)_{-2}^{(0,-2)} + (q + 2, 1, 1)_{2}^{(0,2)}
\]

\[
+ (r, 1)_{-2}^{(-1,0)} + (\mathbf{r}, 1)_{2}^{(1,0)}
\]

\[
(1, 1, 2)_{-1}^{(-3)} + (1, 1, 2)_{1}^{(1,3)} + (q + 2, 1, 2)_{-1}^{(1,-1)} + (q + 2, 1, 2)_{1}^{(-1,1)}
\]

\[
+ (r, 2)_{-1}^{(0,1)} + (\mathbf{r}, 2)_{1}^{(0,-1)}
\]

\[
(1, 1, 1)_{0}^{(0,4)} + (1, 1, 1)_{0}^{(0,-4)} + (q + 2, 1, 1)_{0}^{(2,0)} + (q + 2, 1, 1)_{0}^{(-2,0)}
\]

\[
+ (r, 1)_{0}^{(1,2)} + (\mathbf{r}, 1)_{0}^{(-1,-2)}.
\]

Leaving the $T^3$ model aside for the moment, at this stage we are able to reproduce all homogeneous SK manifolds of section III C 1 by adjusting the field multiplicities, symmetries and representations (and hence couplings) of the Right Yang-Mills theory. The choices of $q$ and $F_q$ (and the corresponding representation $r$) giving the non-symmetric (section II A 1), generic Jordan (section II A 2), magic (section II A 3) and minimally coupled (section II A 4) theories are summarised in Table IX. Note, the first three choices reproduce the previous BCJ double-copy construction of
The semi-simple symmetries and their representations are matched directly to those of the corresponding supergravity theories. The only minor subtlety is the correct identification of the various $U(1)$ charges. Including the additional $U(1)_-$, the correct charges for each $U(1)$ factor appearing in the gravitational theory are given by an invertible linear combination of $C_\perp$ with $C_L$ and $C_F$, which are inherited directly from the Left and Right factors respectively, as described in the final column of Table IX. In these cases, all scalar fields appearing in the supergravity theory transform under a manifest global symmetry, which is sufficient to ensure that the scalar manifold is (locally) homogeneous [25, 62]. By contrast, comparing the $(1, 1, 1)^0_x + (1, 1, 1)^{−x}_0$ terms of (4) and (76) we see that $U(1)_-$ is not a symmetry of the non-symmetric theory and must be discarded. This accords perfectly with the double-copy construction of [25]. In the absence of the $U(1)_-$ the vanishing of the single soft-dilaton/axion limits must be checked independently to establish (local) homogeneity.

Finally, let us briefly comment on the absence of the $T^3$ model. Note, the $P = 0$ minimally coupled model has the same field content and scalar coset as the $T^3$ model, but with different representations as can be seen by comparing (15) with (20). In particular, the two vector potentials and their duals transform as the $4$ and $2 + 2$ of $SL(2,R)$ for the $T^3$ and minimally coupled model, respectively. Using the same starting point as the minimally coupled model, but letting $C_T = 2C_L - C_\perp$ while dropping entirely the second independent $U(1)$, one can reorganise the content into that of the $T^3$ model. Recall, however, that since the $T^3$ model has a symmetric manifold the global $U(1)_-$ is present and we are therefore actually throwing away a symmetry that is inherited from the gauge factors. In terms of the double-copy there will be non-trivial amplitudes in the $T^3$ model that are not generated by the Yang-Mills factors, essentially because we are relaxing the second $U(1)$ symmetry present in the minimally coupled starting point. To give another perspective, the squaring and double-copy constructions are many-to-one; there is no way to pass from minimally coupled to $T^3$. This leaves the possibility of using two $N = 1$ Yang-Mills multiplets, but from Table VII we see immediately that this generates at least one hyper multiplet. The apparent absence of only the $T^3$ model amongst all homogeneous $N = 2$ supergravities coupled to vector multiplets is rather surprising. Although, it should be recalled that the $T^3$ model stands alone in the sense that its five dimensional origin is pure minimal supergravity, which itself does not admit a squaring origin. Moreover it is an isolated case in the classification of symmetric projective special Kähler manifolds [63]. The final logical possibility is that the product of two Yang-Mills theories can have more supersymmetry than the sum of its factors. We leave such speculations for future consideration.

TABLE IX. The choice of $(q, P, \dot{P})$ and $F_q$ for the Right Yang-Mills factor and the required linear combinations of $U(1)$ charges leading to the non-symmetric (section II A 1), generic Jordan (section II A 2), magic (section II A 3) and minimally coupled (section II A 4) $N = 2$ supergravity theories coupled to vector multiplets.
2. Hyper multiplets

In order to reproduce the Q manifolds of section II B let us isolate those terms generating hyper multiplets in (68),

$$
C_2^a \otimes \left( 2(q' + 4)\Phi^a \oplus (t)\varphi^a \right) = (q' + 4 + t/2)H_2,
$$

and label the resulting content under $U(1)^{st} \times SO(q' + 4) \times F_{q'} \times SU(2)_R \times SU(2)_L$. Of course the fields will also be charged under $U(1)_L \times U(1)_-$, but since these factors are absorbed by the SK manifolds of the vector multiplet sector we omit them here.

The resulting content carries the representations:

$$
(q' + 4, 1, 2, 1)_{-1} + (q' + 4, 1, 1, 1)_1 + (t, 1, 1)_{-1} + (t, 1, 1)_1
$$

As for the vector sector we are able to reproduce all homogeneous Q manifolds of section II B by adjusting the field multiplicities, symmetries and representations of the Right Yang-Mills theory. The choice of $(q', P', \hat{P}')$ for the Right Yang-Mills factor (and the corresponding representation $T$) gives the non-symmetric (section II B 1), generic Jordan (section II B 2), magic (section II B 3), minimally coupled (section II B 4), projective quaternionic (section II B 5) and exceptional $T^3$ (section II B 6) theories are summarised in Table X.

| $(q', P', \hat{P}')$ | $F_{q'}$ | $t$ | Theory | Comments |
|---------------------|-----------|-----|--------|----------|

TABLE X. The choice of $(q', P', \hat{P}')$ and $F_{q'}$ for the Right Yang-Mills factor and the required identifications $SU(2)_{L/R}$ leading to the non-symmetric (section II B 1), generic Jordan (section II B 2), magic (section II B 3), minimally coupled (section II B 4), projective quaternionic (section II B 5) and exceptional $T^3$ (section II B 6) theories.

In this case all those theories with symmetric quaternionic manifolds follow straightforwardly from the Right factor since the full isometry group is given by $\mathcal{H} = SU(2)_L \times SO(q' + 4) \times F_{q'} \times SU(2)_R$ or its relevant enhancement, which occurs already in the Right factor before squaring. See for example the magic cases given in Table VI. For instance, for the octonionic magic theory the Right factor scalars $\Phi^a$ and $\varphi^a$ transform irreducibly under the enhanced $E_7 \cong [Conf(\mathfrak{g}^{4L})]_c$ symmetry of the Right factor,

$$
SO(12) \times SU(2)_L' \rightarrow E_7; \\
(12, 2) + (32, 1) \rightarrow 56,
$$

where $SO(q' + 4) \times F_{q'}|_{q'=8} \cong SO(12)$ and $SU(2)_L' \cong SU(2)_R$. From (30) we see that in total the hyper scalars transform as

$$
(56, 1)_1 + (56, 2)_0 + (56, 1)_{-1}
$$
under the combined Left/Right symmetries \( \mathcal{H} \cong [\text{Conf}(S_{3}^{\mathbf{4}})]_{L} \times SU(2) \) where \( SU(2) \cong SU(2)_{L} \). The remaining cases are summarised in Table X, with the appropriate identification of the \( SU(2) \) factors.

The non-symmetric family is a little more subtle. On the gravitational side the hyper multiplet scalars that are singlets under the \( SO(q + 3) \times S_{q}(P, \tilde{P}) \) subgroup of \( \mathcal{H} = SO(q + 3) \times S_{q}(P, \tilde{P}) \times SU(2)_{ns} \) transform under \( \mathcal{H} \) as

\[
(1, 1, 3) + (1, 1, 1), \tag{81}
\]

as can be seen from (24). On the other hand, from (78) we observe that the only singlets in hyper multiplet scalar sector that follow from the product of the Left/Right factors (77) transform as a \((1, 1, 2, 2)\) under the Left/Right symmetries \( SO(q + 3) \times S_{q}(P, \tilde{P}) \times SU(2)_{R} \times SU(2)_{L} \). Note, the 2 of \( SU(2)_{L} \) is required by R-symmetry and hence the only way (81) may be reproduced is by identifying \( SU(2)_{ns} \) with a diagonal subgroup of \( SU(2)_{R} \times SU(2)_{L} \),

\[
SU(2)_{ns} \cong \text{diag}[SU(2)_{R} \times SU(2)_{L}] \Rightarrow SU(2)_{L} \times SU(2)_{L}, \tag{83}
\]

under which

\[
(1, 1, 2, 2) \rightarrow (1, 1, 2 \times 2) = (1, 1, 3) + (1, 1, 1). \tag{84}
\]

The observation that the symmetric Q manifolds have an extra \( SU(2) \) with respect to the non-symmetric case follows from an argument analogous to the treatment of the extra \( U(1)_{-} \) appearing in the symmetric SK manifolds with respect to the non-symmetric SK manifolds. In order to see this, we start once again from the Jordan algebraic embedding \( \mathfrak{J}^{\mathbf{4}}_{3} \supset \mathbb{R} \oplus \mathfrak{J}^{\mathbf{2}}_{3} \), considered now at the level of quasi-conformal symmetries, and then further branch it in order to obtain an \( SO(1, 1) \) generating the 5-grading (here \( q_{2} \cong q_{2}(1, 0) \cong q_{2}(0, 1) \), where \( q = 1, 2, 4, 8 \)):

\[
Q\text{Conf}(\mathfrak{J}^{\mathbf{4}}_{3}) \supset Q\text{Conf}(\mathbb{R} \oplus \mathfrak{J}^{\mathbf{2}}_{3}) \times S_{q} \cong SO(q, 4 + 4) \times S_{q} \\
\cong SO(1, 1) \times SO(q + 3, 3) \times S_{q} \tag{85}
\]

\[
\text{Adj} = (\text{Adj.} 1) + (1, \text{Adj}) + (\text{spin, def}) \\
= (\text{Adj.} 1)_{0} + (1, 1, \text{Adj})_{0} + (q + 6, 1)_{-2} + (\text{spin}, \text{def})_{-1} + (\text{spin, def})_{+1} + (q + 6, 1)_{+2}. \tag{86}
\]

One recognizes that \( \mathcal{G} \) of the homogeneous non-symmetric class of quaternionic manifolds is given by the non-negatively graded part of the branching (86). The aforementioned extra \( SU(2) \) requires in addition the negatively graded part of (86). The two negative grade terms can be present only in the symmetric case, where they generate the enhancement from \( SO(1, 1) \times SO(q + 3, 3) \) to \( SO(q + 4, 4) \). From (85) we observe that in the magic cases a second enhancement takes place, \( SO(q + 4, 4) \times S_{q} \rightarrow Q\text{Conf}(\mathfrak{J}^{\mathbf{4}}_{3}) \) (recall, we have restricted to the special values of \( q = 1, 2, 4, 8 \) here to make this manifest). Note that the two \( SU(2) \) factors are generated by the \( so(4) \) in the maximal compact subalgebra \( so(q + 4) \oplus so(4) \subset so(q + 4, 4) \), while the unique \( SU(2)_{ns} \) appearing in the non-symmetric homogeneous manifolds is generated by the \( so(3) \) summand in \( so(q + 3) \oplus so(3) \subset so(q + 3, 3) \). Although it is not a priori obvious why the restriction \( SU(2)_{ns} \subset SU(2)_{R} \times SU(2)_{L} \) would be required by the double-copy construction, the above symmetry arguments strongly suggest it will be effected at the level of amplitudes.

IV. CONCLUSION

We have shown that all ungauged \( D = 4, \mathcal{N} = 2 \) supergravity theories with homogeneous scalar manifolds are the square of Yang-Mills with two isolated exceptions, pure \( \mathcal{N} = 2 \) supergravity and the \( T^{3} \) model in the vector sector. This completes the classification of all supergravities with eight or more supercharges and homogeneous scalar manifolds in \( D \geq 4 \) with a Yang-Mills squared origin (up to the possibility that more subtle, yet to be appreciated, mechanisms may enter the game). There are two obvious directions for future work (i) \( D = 4, \mathcal{N} = 2 \) supergravities with non-homogeneous scalar manifolds and (ii) \( D = 4, \mathcal{N} = 1 \) supergravities, first with homogeneous (non)symmetric and then non-homogeneous scalar manifolds. We should emphasise, however, that at present it is unclear how one would proceed in the non-homogeneous cases. Finally, one can consider the BCJ colour-kinematic duality compatibility of the Right Yang-Mills factor to determine whether or not all examples appearing in the classification are indeed double-copy constructible. For the non-symmetric hyper multiplet sector we would anticipate a BCJ origin for the identification of the Left and Right \( SU(2) \) factors, which at present is not understood.
ACKNOWLEDGMENTS

We are grateful to Marco Chiodaroli and Henrik Johansson for useful discussions. We would like to thank Gerard \'t Hooft and Antonino Zichichi, directors of the 55th International School Of Subnuclear Physics, EMFCSC, Erice, Sicily, for the stimulating atmosphere in which the final stages of the project were conceived. The work of LB is supported by a Schrödinger Fellowship. MJD is grateful to the Leverhulme Trust for an Emeritus Fellowship and to Philip Candelas for hospitality at the Mathematical Institute, Oxford. This work was supported by the STFC under rolling grant ST/G000743/1.

Appendix A: Enhancements

In this appendix we address the problem of enhancements. It should be obvious from equation (69) that upon squaring, we take the direct product between the global internal symmetry groups of the two Yang-Mills sides which can schematically be expressed as $\text{Sym}_L \times \text{Sym}_R \times U(1)_-$. In the case of a symmetric scalar coset. Then Table IX and Table X give the explicit rules of how to go from this direct product of groups to the $H \times H$ of the desired supergravity theory. In the non-symmetric cases one needs to drop $U(1)_-$ and identify the two $\text{Sym}_L \times \text{Sym}_R$. In the symmetric cases things differ between the hyper and vector multiplet sectors. In the hyper multiplet scalar sector the full isometry group is given by $H = \text{SU}(2)_L \times \text{Sym}_R$. However, in the vector multiplet scalar sector there are cases where the isometry group $H$ is given directly by the remaining factors of $\text{Sym}_L \times \text{Sym}_R \times U(1)_-$ and other cases where these need to be further enhanced in order to form the full $H$. The purpose of this section is to understand when this enhancement occurs in the symmetric vector multiplet sector and study its Yang-Mills origin.

To answer the question of when such enhancements occur in the symmetric cases it is enough to observe that (1) they never occur in the hyper sector and (2) they do not occur in the generic-Jordan vector sector series. Having made this observation the answer can be summarised as follows:

Whenever the scalars parametrising a symmetric coset space originate from both “boson $\otimes$ boson” and “fermion $\otimes$ fermion” terms, an enhancement is required.

In particular, the hyper sector scalars always have a purely “boson $\otimes$ boson” origin and no enhancement is required, consistent with the identification $H = \text{SU}(2)_L \times \text{Sym}_R$. Similarly, in the generic Jordan vector sector series $P = \dot{P} = 0$ so that the Right theory has no fermions, again implying that no enhancement is required.

The more interesting question is how, when needed, these enhancements arise in terms of the Yang-Mills factors:

What is the Yang-Mills origin of the extra generators required to enhance the symmetries to the full $H$ isometry group?

This question was addressed in the context of squaring pure super-Yang-Mills theories in [3, 41, 42]. It is instructive to recall the problem through the paradigmatic example of $\mathcal{N} = 8$ supergravity as the product of two pure $\mathcal{N} = 4$ super-Yang-Mills, each having an $SU(4)$ global internal R-symmetry. The problem there was to find the missing generators required to enhance $SU(4) \times SU(4) \times U(1)_- \subset SU(8)$. The adjoint decomposition goes as:

$$63 \rightarrow (15,1)_0 + (1,15)_0 + (1,1)_1 + (4,\bar{4})_1 + (\bar{4},4)_{-1},$$

(A1)

which means that the missing generators should carry defining and conjugate-defining indices with respect to the R-symmetry groups. Furthermore the generators should act simultaneously on both factors and should turn bosonic into fermionic states and vice versa. All these features led us to propose that the missing generators where composed by the tensor product of the Left and Right supersymmetry generators. Indeed, the tensor product of the Left and Right supercharges provided a precise guide to constructing the generators. The caveat here is that strictly speaking the generators cannot be those of supersymmetry because the momentum factors arising from the partial derivatives should be removed by hand. This caveat can be equivalently thought as the problem of trying to build a dimensionless bosonic parameter from the product of two supersymmetry parameters.

As a concrete example of the theories studied in this paper we can focus on the octonionic magic vector multiplet sector. We need to find the Yang-Mills origin of the enhancement $SO(10) \times U(1) \subset E_6$ where the adjoint
representation decomposes as:

\[ 78 \rightarrow 45_0 + 16_3 + 10_{-3}. \]  

It is instructive to notice that while the simultaneous supersymmetry picture now fails, since the Right theory is non-supersymmetric, the missing generators still carry representations similar to those of the spinors and still need to mix bosonic with fermionic states. It should be emphasised that although the combined Left/Right generators correspond to a legitimate bosonic symmetry transformation on the supergravity side, the individual generators themselves to not induce a symmetry transformation on the Yang-Mills factors individually.

In the Left sector, the vector multiplet is described by the on-shell superfield,

\[ V_{2-} = \bar{\phi} + \eta^a \psi_{a-} + \eta^I \eta^I V_-, \]  

and similarly for \( V_+ \). For the half-hyper, we have,

\[ C_2 = \chi_+ + \eta^a \sigma_a + \eta^I \eta^I \chi_-, \]  

where the gauge indices have been omitted for simplicity. The action of the desired ladder operator on the superfields is simply:

\[ [L_L]_- V_{2+} = C_2, \]
\[ [L_L]_- C_2 = V_{2-}, \]
\[ [L_L]_- V_{2-} = 0, \]  

and similarly for \([L_L]_+\). It should be noted that the operator carries both adjoint and defining gauge indices which are contracted accordingly with the superfield it acts on. Using the standard (anti)-commutation relations, we can write the ladder operator as

\[ [L_L]_- := \int d^2 p \sum_{k=0} \left[ C_{2(k)} (V_{2+ (k)})^\dagger + V_{2- (k)} (C_{2(k)})^\dagger \right], \]  

where we defined \( S_{(k)} \equiv \phi^I \eta^I S |_{(\eta=0)}. \)

The states of the Right sector can be written as

\[ A_+, \quad \lambda^I_{+x}, \quad \phi^m, \quad \lambda^I_{-x}, \quad A_-, \]  

where again the gauge indices have been omitted. The action of the desired ladder operator on the states is:

\[ [L_R]_{+x}^- A_+ = \lambda^I_{+x}, \]  
\[ [L_R]_{+y}^- \lambda^I_{+y} = \phi^m (\gamma_m)_{xy} \mathcal{I}^I, \]  
\[ [L_R]_{-x}^- \phi^m = \lambda^I_{-x} (\gamma_m)_{xy} \mathcal{I}^I, \]  
\[ [L_R]_{-x}^- \lambda^I_{-x} = A_- \epsilon^I J, \]  
\[ [L_R]_{-x}^- A_- = 0, \]  

and similarly for the raising operator \([L_R]^x \). In the minimally coupled cases \( \phi^m = 0 \). In the magic cases \( \mathcal{I}^{IJ} = \mathbb{1} \) for \( n = 1, 2, 8 \) and \( \mathcal{I}^{IJ} = \epsilon^{IJ} \) for \( n = 4 \). We can use the standard (anti)-commutation relations,

\[ [A_+(p), A_+^I (q)] = (2\pi)^3 2 E_p \delta^3(\bar{p} - \bar{q}), \]
\[ (\lambda^I_{+x} (p), (\lambda^I_{+y})^y_j (q)) = (2\pi)^3 2 E_p \delta^3(\bar{p} - \bar{q}) \delta^I_j, \]
\[ [\phi^m (p), \phi^n (q)] = (2\pi)^3 2 E_p \delta^3(\bar{p} - \bar{q}) \delta^mn, \]  

to pack the ladder operator in the simple form

\[ [L_R]_{+x}^- := \int d^2 p \left[ -\lambda^I_{+x} (A_+)^I + \phi^m (\gamma_m)_{xy} (\lambda^I_{+y})^I + \lambda^I_{-x} (\gamma_m)_{xy} (\phi^m)^I - A_- (\lambda^I_{-x})^I \right]. \]  

It is now a straightforward exercise to show that the missing enhancement generators can be constructed as,

\[ [E_{+}]_{+x}^I = [L_L]_+ \otimes [L_R]_{+x}^- \quad \text{and} \quad [E_-]_{+x}^I = [L_L]_- \otimes [L_R]_{+x}^I. \]
