Abstract. We observe a different type of complex solutions in the isotropic spin-1/2 Heisenberg chain starting from \( N = 12 \), where the central rapidity of some of the odd-length strings becomes complex so that not all the strings self-conjugate individually. We show that there are at most \((N-2)/2\) singular solutions for \( M = 4, M = 5 \) down-spins and at most \((N^2 - 6N + 8)/8\) singular solutions for \( M = 6, M = 7 \) down-spins in an even-length chain with \( N \geq 2M \). Correspondence of the non self-conjugate string solutions and the singular string solutions to the rigged configurations has also been shown.

Keywords: algebraic structures of integrable models, integrable spin chains (vertex models), quantum integrability (Bethe ansatz), symmetries of integrable models

1. Introduction

Bethe’s solution of the isotropic spin-1/2 Heisenberg model in 1D, by a method known as the coordinate Bethe ansatz [1], is one of the seminal works in the field of integrable models. For a detailed investigation on the method and its variants and other related works see [2–11]. However, deriving the Bethe ansatz equations and the form of the eigenvalues and eigenvectors is only one part of the story. The other important part is to extract the numerical values of the rapidities from the set of the Bethe ansatz equations. Because of the high degree of nonlinearity and multi-variate nature it is practically impossible to analytically solve the Bethe ansatz equations even for a modest length of the spin chain. One, therefore, needs to seek numerical solutions using methods such as iterations, the Newton-Raphson, homotopy continuations, etc. There has been some effort to find the numerical solutions of the Bethe ansatz equations using different techniques and the eigenvalues have been found which have an excellent match with direct diagonalization of the Hamiltonian.

Apart from the real solutions, which are much easier to find out, there are complex solutions of the Bethe ansatz equations, which need extra effort to calculate. Bethe himself investigated this problem for a finite length spin chain and found that if there are complex solutions then they come in complex conjugate pairs and arrange themselves in a string-like structure [1]. These complex solutions, responsible for the formation of bound states, lead to the so-called string hypothesis [12]. The importance of the numerical computations of all the Bethe solutions are, on the one hand, to check the completeness of the spectrum of the Hamiltonian and, on the other hand, the knowledge of the numerical solutions necessary for the computation of correlation functions, form factors [13, 14] and other physical quantities of the model.
Although the string hypothesis gives satisfactory results in the thermodynamic limit and counts the total number of states correctly in the general case, it has many drawbacks and some exceptions to it have been found. For example, if the string hypothesis is valid in all respects then for a large length chain the imaginary part of the rapidities of 2-string should converge to ±1/2. However, it has been shown in [15] that some of the 2-string rapidities $\lambda_\pm$, behave as $\text{Re}(\lambda_\pm) \sim N$, $\text{Im}(\lambda_\pm) \sim \pm \sqrt{N}$ for large length $N$ spin chains. Nevertheless, there are some 2-strings which for large $N$ and large Bethe quantum numbers deform back to two real rapidities [16–19], which are observed numerically. Despite these drawbacks, the string hypothesis has been very helpful in numerical analysis in the iteration method to obtain a good initial guess for the finite length chains. Exploiting the string hypothesis and taking into account the deformations, the complete string solutions for $N = 8$ and $N = 10$ length isotropic spin-1/2 Heisenberg chains are obtained in [20]. String solutions up to $N = 14$ have been obtained in [21] and its supplement by making use of the homotopy continuation method to show that there are too many solutions of the Bethe ansatz equations and only some of them, which obey the self-conjugacy condition, are the physical solutions of the Heisenberg model. Here, we note that we call a solution of the Bethe ansatz equations physical if it leads to an eigenvector of the Hamiltonian.

Usually, a set of solutions to the Bethe ansatz equations consists of strings of different lengths. As mentioned above, one key constraint to the solutions of the Bethe ansatz equations is that they are self-conjugate [22]. While implementing this constraint in the string hypothesis it is usually assumed that self-conjugacy is to be satisfied within a string [20], a condition, motivated by the observation of the short length spin chains, is too restrictive to be valid for all solutions of higher-length spin chains. We, therefore, relax the imposition of the self-conjugacy criterion to the whole set of rapidities not necessarily within a string, making the strings in a solution individually not self-conjugate. We show that our self-conjugacy criterion allows us to obtain some solutions which are not fitted within the standard deformed string picture, which is one of our motivations in this work. For even-length chains, up to $N = 10$ the string solutions, although deformed, still obey the string structure and the restrictive self-conjugacy condition. First, breakdown of the string structure for the physical solutions of even-length chains occurs in $N = 12$, as some of the strings become non self-conjugate and therefore need the most relaxed self-conjugacy condition. We discuss this feature of the string solutions here with an example of $N = 12$. Although numerical solutions for $N = 12$ are obtained in [21] using the homotopy continuation method we here obtained the solutions by the iteration method using Mathematica and exploiting the string hypothesis. Here, we note that some different types of solutions of the Bethe ansatz equations in the anisotropic Heisenberg models are studied in [23–26].

Moreover, recently a lot of works on the physical singular solutions have been reported in the literature [21, 27–29]. The singular solutions as we know are an essential component of the spectrum and need a proper regularization scheme to derive the correct physical states and the eigenvalues. It is also possible to map these solutions and even the regular solutions to a type of combinatorial objects known as rigged configurations [30–32]. Based on the symmetry of the singular solutions for even-length chains we classify the solutions in different categories, which allow us to simplify the Bethe ansatz equations significantly up to $M = 7$ down-spins. Studying the algebraic aspects of polynomials we...
Non self-conjugate strings, singular strings and rigged configurations in the Heisenberg model

estimate the number of singular solutions present at most for even-length spin chains up to \( M = 7 \) down-spins. We also study the aspect of mapping of the Bethe states to rigged configurations for singular solutions as well as solutions with non self-conjugate strings.

Our study enables us to identify all the physical singular solutions present in the \( N = 12 \) case and map them to rigged configurations. It also simplifies the Bethe ansatz equations for the singular solutions significantly up to \( M = 7 \) down-spins with even \( N \) so that the physical singular solutions and their total number are obtained systematically.

We organize this paper in the following fashion: In the next section, we briefly present the isotropic spin-1/2 chain and its solutions in terms of the algebraic Bethe ansatz method. In section 3, we discuss the non self-conjugate strings and explain them with the example of \( N = 12 \). In section 4, we discuss the singular solutions, their classification and give an estimate of the number of singular solutions. In section 5, we discuss rigged configurations and their correspondence with \( N = 12 \) case for non self-conjugate string solutions and singular string solutions and finally we conclude.

2. Algebraic Bethe ansatz

The Hamiltonian of a spin-1/2 chain with length \( N \) under the periodic boundary conditions is given by

\[
H = J \sum_{i=1}^{N} \left( S_i^x S_{i+1}^x + S_i^y S_{i+1}^y + S_i^z S_{i+1}^z - 1/4 \right),
\]

where \( J \) is the coupling constant and \( S_i^j (j = x, y, z) \) the spin at position \( i \) and in \( j \)-direction. In the algebraic Bethe ansatz formulation one can construct a Bethe state in the case of \( M \) down spin sector as

\[
|\lambda_1, \lambda_2, \ldots, \lambda_M \rangle = \prod_{\alpha=1}^{M} B(\lambda_\alpha) |\Omega \rangle,
\]

from the reference state \( |\Omega \rangle \) with all up spins by acting the \( B(\lambda_\alpha) \) matrix. To obtain the \( B(\lambda_\alpha) \) matrix we need the Lax operator

\[
L_\gamma(\lambda) = \begin{pmatrix}
\lambda - iS_\gamma^z & -iS_\gamma^- \\
-iS_\gamma^+ & \lambda + iS_\gamma^z
\end{pmatrix},
\]

where \( S_\gamma^\pm = S_\gamma^x \pm iS_\gamma^y \) are the Pauli spin-1/2 matrixes. Each element of this matrix acts nontrivially on the \( \gamma \)-th lattice site of the Heisenberg model. One can get \( B(\lambda_\alpha) \) from the monodromy matrix

\[
T(\lambda) = L_N(\lambda) L_{N-1}(\lambda) \cdots L_1(\lambda) = \begin{pmatrix} A(\lambda) & B(\lambda) \\ C(\lambda) & D(\lambda) \end{pmatrix}.
\]

The Bethe state (2) can also be written in a very useful form as \[33\]

\[
\prod_{\alpha=1}^{M} B(\lambda_\alpha)|\Omega \rangle = (-2i)^M \prod_{j<k}^{M} \frac{\lambda_j - \lambda_k + i}{\lambda_j - \lambda_k} \prod_{j=1}^{M} \frac{(\lambda_j - i/2)^N}{\lambda_j + i/2} \times \prod_{1 \leq x_1 < x_2 \ldots < x_M \leq N} \prod_{\mathcal{P} \in \mathcal{S}_M} \prod_{P_j < P_k} \left( \frac{\lambda_{P_j} - \lambda_{P_k} - i}{\lambda_{P_j} - \lambda_{P_k} + i} \right)^{H(j-k)} \prod_{j=1}^{M} \frac{\lambda_{P_j} + i/2}{\lambda_{P_j} - i/2} x_j \prod_{j=1}^{M} S_{x_j}^z |\Omega \rangle,
\]

doi:10.1088/1742-5468/2015/02/P02004 4
where $P$ are elements of the permutation group $S_M$ of the $M$ numbers and $H(x)$ is the Heaviside step function $H(x) = 1$ for $x > 0$ and $H(x) = 0$ for $x \leq 0$.

When the rapidities $\lambda_\alpha$ satisfy the well known Bethe ansatz equations

$$\left( \frac{\lambda_\alpha - i/2}{\lambda_\alpha + i/2} \right)^N = \prod_{\beta \neq \alpha} \frac{\lambda_\alpha - \lambda_\beta - i}{\lambda_\alpha - \lambda_\beta + i}, \quad \alpha = 1, 2, \cdots, M, \quad (6)$$

then the Bethe state given by equation (2) (and (5)) becomes the highest-weight Bethe eigenstate. We also call the solutions of (6) the Bethe roots. The eigenvalue of the Hamiltonian (1) for the $M$ down-spin configuration is then given by

$$E = -\frac{J}{2} \sum_{\alpha=1}^{M} \frac{1}{(\lambda_\alpha^2 + 1/4)}. \quad (7)$$

A convenient way to deal with the Bethe ansatz equations is to take the logarithm of equation (6)

$$2 \arctan(2\lambda_\alpha) = J_\alpha \frac{2\pi}{N} + \frac{2}{N} \sum_{\beta \neq \alpha} \arctan(\lambda_\alpha - \lambda_\beta) \mod 2\pi, \quad (8)$$

where the Bethe quantum numbers, $\{J_\alpha, \alpha = 1, 2, \cdots, M\}$, take integral or half integral values, depending on whether $N - M$ is odd or even, respectively. However, since $J_\alpha$ are repetitive in a given state, it is not useful for counting the number of states of the model concerned. But, it is possible to obtain non-repetitive quantum numbers with the help of the string hypothesis, which says that the rapidities for $M$ down-spins are arranged in a set of strings as

$$\lambda_{aa}^j = \lambda_{aa}^j + \frac{i}{2} (j + 1 - 2a) + \Delta_{aa}^j, \quad a = 1, 2, \cdots, j, \quad \alpha = 1, 2, \cdots, (9)$$

where the string center $\lambda_{aa}^j$ is real, $j$ is the length of the string, $\alpha$ accounts for the number of the $j$-strings and $\Delta_{aa}^j$ are the string deviations. In the limit $\Delta_{aa}^j \to 0$, the Bethe ansatz equation (6) reduce to [12]

$$\arctan \frac{2\lambda_\alpha^j}{j} = \pi \frac{I_\alpha^j}{N} + \frac{1}{N} \sum_{k=1}^{N_s} \sum_{\beta} M_k \Theta_{jk} \left( \lambda_\alpha^j - \lambda_\beta^k \right) \mod \pi,$$

$$\Theta_{jk}(\lambda) = (1 - \delta_{jk}) \arctan \frac{2\lambda}{|j - k|} + 2 \arctan \frac{2\lambda}{|j - k| + 2} + \cdots + 2 \arctan \frac{2\lambda}{j + k - 2}$$

$$+ \arctan \frac{2\lambda}{j + k}, \quad (10)$$

where $M_k$ is the number of $k$-strings present in the $M$ down-spin state and $N_s$ is the length of the largest string such that $\sum_k N_k M_k = M$. The Takahashi quantum numbers $I_\alpha^j$, which are non-repetitive, are given by

$$| I_\alpha^j | \leq \frac{1}{2} \left( N - 1 - \sum_{k=1}^{N_s} [2 \min(j, k) - \delta_{j,k}] M_k \right). \quad (11)$$

doi:10.1088/1742-5468/2015/02/P02004
3. Non self-conjugate strings

In this section, we present the non-string type solutions, which start to occur from the $N = 12$ case. One of the important ingredients for an effective iteration method is to start the numerical procedure with a very good initial guess. In the case of the Bethe equation (6) it can be found by solving the Takahashi equation (10). One then needs to find the deviations $\Delta_{aa}^j$ of the string to obtain the actual roots. In the string hypothesis these deviations are supposed to be purely imaginary and decrease exponentially with respect to $N$. In finite-size spin chains, however, there are deviations of the string center, which leads to the form [20]

$$\Delta_{aa}^j = \epsilon_{aa}^j + i \delta_{aa}^j,$$

where $\epsilon_{aa}^j$ and $\delta_{aa}^j$ are real. Since the Bethe roots are self-conjugate there should be a corresponding restriction on the deviations. One choice is to consider self-conjugacy within a string of length $j$, which translates to $\Delta_{aa}^j = (\Delta_{aa}^{j+1})^*$. A consequence of this picture is that the central rapidity of an odd-length string is always real and there is as such no relation between different strings in an eigenstate. For $N = 8$ and $N = 10$ we can recover all the string solutions from this consideration of the string picture and it is therefore sufficient to restrict the self-conjugacy condition within a string. However, as we increase the length $N$ of the spin chain it is not possible to recover all the string solutions since the above self-conjugacy condition is too restrictive if we assume that deviations are small. Note that in the string hypothesis it is crucial to construct the strings in such a way that the deviations (12) are small enough so that the $\Delta_{aa}^j \rightarrow 0$ limit leads to an approximate solution of the Bethe ansatz equations, which satisfies the Takahashi equation (10) and gives the Takahashi quantum numbers (11). One therefore needs to impose the self-conjugacy condition on the whole set of strings $\{\lambda_{aa}^j\} = \{\lambda_{aa}^j\}^*$ as mentioned in the introduction. Keeping the deviations small and relaxing the self-conjugacy to the whole set of strings, we obtain some solutions, which are not self-conjugate. We call such solutions non self-conjugate string solutions.

To clarify the point with concrete examples let us consider a state of $M = 5$ downspins in a $N = 12$ spin chain, with two 1-strings ($M_1 = 2$) and one 3-string ($M_3 = 1$). If we consider the self-conjugacy condition only within each string then the Bethe roots can be parametrized as

$$\{\lambda_1\}, \{\lambda_2\}, \{\lambda + \epsilon + (1 + \delta)i, \lambda, \lambda + \epsilon - (1 + \delta)i\},$$

where $\lambda_1, \lambda_2, \lambda, \epsilon, \delta$ are real parameters which we have to evaluate numerically. We put curly brackets to separate different strings. All the physical solutions for $N = 12, M = 5$, $M_1 = 2, M_3 = 1$ though fall into this category except two solutions where the roots can be parametrized as

$$\{\lambda_1\}, \{\lambda + i \delta_1\}, \{\lambda + \epsilon + (1 + \delta_2)i, \lambda - i \delta_1, \lambda + \epsilon - (1 + \delta_2)i\},$$

where $\lambda_1, \lambda, \epsilon, \delta_1, \delta_2$ are real parameters. In table 1 two such solutions of this kind are shown where one of the two 1-strings becomes complex conjugate to the central rapidity of the 3-string and therefore the 1-string and the 3-string become non self-conjugate individually but remain self-conjugate when considered collectively. In all the tables $I_n$ represent the Takahashi quantum numbers for the $n$-strings.
Non self-conjugate strings, singular strings and rigged configurations in the Heisenberg model

Table 1. Non self-conjugate Bethe roots for \( N = 12, M = 5 \). There are only 2 solutions with two 1-strings and one 3-string.

| \( J \) | \( I_n \) | \( \lambda \) | \( E \) | Rigged configuration |
|---|---|---|---|---|
| 1. | 2 | \( \frac{3}{2} \) | 0.180 714 318 631 830 55 | \(-3.600 693 256 269 325 55 \) | \( \frac{E}{2} \) |
| 4 | | 0.491 814 213 695 899 34 + 0.961 471 132 379 080 9i | | 6 | 5 |
| 3 | 1 | 0.444 763 506 448 639 27 + 0.018 770 199 402 377 38i | | 6 | 5 |
| 5 | | 0.491 814 213 695 899 34 − 0.961 471 132 379 080 9i | | 6 | 5 |
| 2. | \(-3\) | \( \frac{5}{2} \) | \(-0.180 714 318 631 830 55 \) | \(-3.600 693 256 269 325 55 \) | \( \frac{E}{2} \) |
| \(-4\) | | \(-0.491 814 213 695 899 34 \) | | 6 | 1 |
| \(-3\) | \( \frac{1}{2} \) | \(-0.444 763 506 448 639 27 \) | | 6 | 1 |
| \(-5\) | | \(-0.491 814 213 695 899 34 + 0.961 471 132 379 080 9i \) | | 6 | 1 |

Another example is present in the \( M = 6 \) down spin sector, with one 1-string (\( M_1 = 1 \)), one 2-string (\( M_2 = 1 \)) and one 3-string (\( M_3 = 1 \)). Again, if we consider self-conjugacy for each string then the Bethe roots can be parametrized as

\[
\{ \lambda_2 \}, \{ \lambda_1 + \frac{i}{2} (1 + 2 \delta), \lambda_1 - \frac{i}{2} (1 + 2 \delta) \}, \{ \lambda + \epsilon + (1 + \delta_1)i, \lambda, \lambda + \epsilon - (1 + \delta_1)i \}, \tag{15}
\]

where \( \lambda_1, \lambda_2, \lambda, \delta, \delta_1, \epsilon \) are real parameters. All the solutions fall into this category except the three solutions which follow

\[
\{ \lambda + i \delta_1 \}, \{ \lambda_1 + \frac{i}{2} (1 + 2 \delta), \lambda_1 - \frac{i}{2} (1 + 2 \delta) \}, \{ \lambda + \epsilon + (1 + \delta_2)i, \lambda - i \delta_1, \lambda + \epsilon - (1 + \delta_2)i \}, \tag{16}
\]

where \( \lambda, \lambda_1, \delta_2, \delta, \delta_1, \epsilon \) are real parameters. We can still use (14) and (16) to get a relation between the Bethe quantum numbers \( J_i \) and the Takahashi quantum numbers \( I_{\alpha n} \) by first simply taking \( \delta_1 \to 0 \) limit in the expressions of the two rapidities \( \lambda + i \delta_1 \) and \( \lambda - i \delta_1 \). We note that in the \( \delta_1 \to 0 \) limit the two rapidities do not become equal to each other, rather they go to two distinct rapidities, \( \lim_{\delta_1 \to 0} \lambda + i \delta_1 \to \lambda_2 \) and \( \lim_{\delta_1 \to 0} \lambda - i \delta_1 \to \lambda \). Then (14) and (16) reduce to the standard string roots of (13) and (15) respectively, which allow us to obtain the Takahashi quantum numbers in terms of the Bethe quantum numbers. In table 2 the three solutions of the form (16) have been shown.

4. Singular strings

Singular string solutions of the Bethe equations are special in the sense that the energy eigenvalue diverges and the Bethe state vanishes without regularization and therefore we need to have a suitable regularization scheme [10, 27–29, 36] to make everything finite. It is also an essential part of the spectrum because without the singular solutions the Hilbert space of the Hamiltonian is not complete. Recently, there has been much interest in singular solutions and it is also possible to map all the singular solutions to rigged configurations. Solutions of the form

\[
\{ \lambda_1 = \frac{i}{2}, \lambda_2 = -\frac{i}{2}, \lambda_3, \lambda_4, \cdots, \lambda_M \}, \tag{17}
\]

doi:10.1088/1742-5468/2015/02/P02004
Non self-conjugate strings, singular strings and rigged configurations in the Heisenberg model

Table 2. Non self-conjugate Bethe roots for $N = 12$, $M = 6$. There are three solutions with one 1-string, one 2-string and one 3-string.

| $J$   | $I_n$ | $\lambda$ | $E$          | Rigged configuration |

| 5/2   |       | 0.752 213 256 639 834 + 0.507 293 831 282 871i |              |                     |
| −9/2  | 03    | −0.367 308 040 796 292 − 0.991 797 190 897 116i |              | 6                   |
| −3/2  |       | −0.384 905 215 843 542 − 0.0190 612 670 356 019i |              |                     |
| −11/2 |       | −0.367 308 040 796 292 + 0.991 797 190 897 116i |              |                     |

are called singular because two of the roots $\lambda_1, \lambda_2$ make the state and the corresponding eigenvalue ill-defined. It has been numerically observed that the roots of a singular state for even $N$ are distributed symmetrically. We assume that for the physical singular solutions the following condition is satisfied

$$\sum_{\alpha=1}^{M} \lambda_{\alpha} = 0 .$$  \hspace{1cm} (18)

The condition (18) is satisfied for any symmetrically distributed roots, which may or may not be singular. We note that the condition (18) has been conjectured in [35] for even length spin chain. Another point is that the singular solutions in [27] for even $N$, which do not satisfy the condition (18), are not physical. In the singular 2-string $\{\pm \frac{i}{2}\}$ case the Bethe eigenstate (5) takes a simple form [16,21]

$$|\Psi⟩_2 \equiv \sum_{j=1}^{N} (-1)^{j} S_{j}^{z} S_{j+1}^{z} |\Omega⟩ .$$  \hspace{1cm} (19)

Based on (18) and the self-conjugacy condition we can classify the different singular states for a fixed number of down spins. For $M = 2$, the only singular solution is of the form

$$\{\frac{i}{2}, -\frac{i}{2}\} ,$$  \hspace{1cm} (20)

which is given for $N = 12$ in table 3. For $M = 3$ the only singular solution possible is

$$\{\frac{i}{2}, -\frac{i}{2}, 0\} ,$$  \hspace{1cm} (21)

which is given in table 4. Note that for $M = 2$ and $M = 3$, there is only one singular state for any even $N \geq 4$. For $M = 4$, there are two different classes of singular solutions

$$\{\frac{i}{2}, -\frac{i}{2}, a_1, -a_1\} \quad \text{for} \quad a_1 \in \mathbb{R} ,$$  \hspace{1cm} (22)
Non self-conjugate strings, singular strings and rigged configurations in the Heisenberg model

Table 3. Singular Bethe roots for $N = 12$, $M = 2$. There is one solution with one 2-string.

| $J$  | $I_n$ | $\lambda$ | $E$  | Rigged configuration |
|------|-------|-----------|------|----------------------|
| 5/2  | 0     | 0.5i      | -1.0 | 8 x 4                |
| 7/2  | -0.5i |           |      |                      |

Table 4. Singular Bethe roots for $N = 12$, $M = 3$. There is one solution with one 1-string and one 2-string.

| $J$  | $I_n$ | $\lambda$ | $E$  | Rigged configuration |
|------|-------|-----------|------|----------------------|
| 0    | 0     | 0.0       | -3.0 | 6 x 3                |
| 3    | 0     | 0.5i      |      | 8 x 4                |
| 3    | -0.5i |           |      |                      |

\[
\left\{ \frac{i}{2}, -\frac{i}{2}, ia_1, -ia_1 \right\} \text{ for } a_1 \in \mathbb{R}. \quad (23)
\]

In Table 5 we give the first type of solutions and in Table 6 the second type of solutions. By substituting the singular roots (22) or (23) in the Bethe ansatz equation (6) we obtain a polynomial equation for a single variable $x$

\[
\left( \frac{x-i}{x+i} \right)^{N-2} = \frac{x-3i}{x+3i}, \quad \text{for} \quad N = 8, 10, 12, \ldots, \quad (24)
\]

where $x$ is either $2a_1$ or $2ia_1$, of equations (22) and (23), respectively. This is a polynomial equation of degree $N - 2$ which can be seen from the simplified form

\[
f(x) = A_{N-2}x^{N-2} + A_{N-4}x^{N-4} + \cdots + A_{N-2-2r}x^{N-2-2r} + \cdots + A_0 = 0, \quad (25)
\]

where the coefficients $A_{N-2} = \frac{N-2}{2} - 3$, $A_{N-4} = \frac{N-4}{2} - 3$, ..., $A_0 = -3(1)^{(N-2)/2}$ are all real. It is useful to write the general form of the coefficients as

\[
A_{N-2-2r} = (-1)^r \left[ \frac{N-2}{2} - 3 \right], \quad \text{for} \quad r = 0, 1, 2, \ldots, (N-2)/2. \quad (26)
\]

It is manifest that if $x$ is a root of the polynomial then $-x$ is also a root, which accounts for the two rapidities of $M = 4$ singular solution in (22) and (23). According to the fundamental theorem of algebra the polynomial equation (25) has at most $N - 2$ distinct roots (real or complex) and since the coefficients are all real the complex roots will occur in complex conjugate pairs if there are any. Considering the fact that two roots of opposite signs of (25) constitute one singular root we find that the total number of singular roots $N$ for $M = 4$ is at most

\[
N = \frac{N-2}{2}, \quad \text{for} \quad N = 8, 10, 12, \ldots. \quad (27)
\]

One test which guarantees that the the total number of singular solutions is exactly given by (27) is to show that the discriminant of the polynomial $f(x)$ in (25) is not zero, which we cannot prove here. But a numerical check for many different values of the chain lengths shows that discriminants are indeed non-zero and negative. It follows that the roots are all distinct and all account for the singular solutions. The number of sign changes \[V_+\]
Table 5. Singular Bethe roots for $N = 12, M = 4$. There are four solutions with two 1-strings and one 2-string.

| $J$   | $I_n$ | $\lambda$           | $E$        | Rigged  |

| $-9/2$|       |           | $-1.502\,976\,465\,754\,898i$ |         |   |

of the coefficients (26) of $f(x)$ and the number of sign changes $V_-$ of the corresponding coefficient of $f(-x)$ are the same and given by

$$V_\pm = \frac{N-2}{2} - 1, \quad \text{for} \quad N = 8, 10, 12, \ldots .$$  \hspace{1cm} (28)

Then, according to the Descartes’ rule of sign, the number of real positive roots $n_+$ and the number of real negative roots $n_-$ are bounded by

$$n_\pm \leq V_\pm,$$  \hspace{1cm} (29)

where the upper and lower sign of the suffix of the left hand side should be considered with the upper and lower sign of the suffix of the right hand side, respectively. Equation (29) implies that there are at most $(N-2)/2 - 1$ number of solutions of the type (22) and therefore at least 1 solution of the type (23). Here and for $M = 5$ case below we assume that the complex root of (25) is all purely imaginary, for which we do not have any
Non self-conjugate strings, singular strings and rigged configurations in the Heisenberg model

Figure 1. The energy eigenvalues for the singular solutions for $N = 500, M = 4$ with absolute value $|\lambda|$ of the form, $a_1$ or $ia_1$ of equations (22) and (23), respectively. Up to $N = 500$, we obtained only one solution of the form $ia_1$ for every even-integer $N \geq 8$, with $ia_1 \rightarrow 1.5i$ for large $N$ and the corresponding eigenvalue $E \rightarrow -0.5$ as can be seen from the isolated point in the figure.

analytical proof but it is supported by numerical observations up to $N = 500$. So far our numerical solutions shows that there are exactly $(N - 2)/2 - 1$ number of solutions of the first type and only 1 solution of the second type as can be seen from figure 1 obtained for $N = 500$.

In a similar fashion, singular solutions for $M = 5$ can be obtained, where there exist two different types of singular solutions

\[
\left\{ \frac{i}{2}, -\frac{i}{2}, 0, a_1, -a_1 \right\} \quad \text{for} \quad a_1 \in \mathbb{R}, \tag{30}
\]

\[
\left\{ \frac{i}{2}, -\frac{i}{2}, 0, ia_1, -ia_1 \right\} \quad \text{for} \quad a_1 \in \mathbb{R}. \tag{31}
\]

In table 7 we give the first type of solutions and in tables 8 and 9 the second type of solutions. One can again substitute (30) or (31) in the Bethe ansatz equation (6) to obtain a polynomial equation for a single variable $x = 2a_1$ or $2a_1i$

\[
\left( \frac{x - i}{x + i} \right)^{N-2} = \frac{x - 3i}{x + 3i} \times \frac{x - 2i}{x + 2i}, \quad \text{for} \quad N = 10, 12, 14, \cdots. \tag{32}
\]

Note that $x = 0$ is a trivial solution of this equation which is not a Bethe roots. So, after factoring out $x$ from (32) we again obtain a polynomial equation of the form (25) but now the coefficients are given by

\[
B_{N-2-2r} = (-1)^r \left[ N-2C_{2r+1} + 6N-2C_{2r-1} - 5N-2C_{2r} \right], \quad \text{for} \quad r = 0, 1, 2, \cdots, (N - 2)/2. \tag{33}
\]

We can show that the number of sign changes $V_+$ of the coefficients (33) of $f(x)$ and the number of sign changes $V_-$ of the corresponding coefficient of $f(-x)$ are the same

\[
V_\pm = \frac{N - 2}{2} - 2, \quad \text{for} \quad N = 10, 12, 14, \cdots. \tag{34}
\]

Applying the Descartes’ rule (29) now implies that there are at most $(N - 2)/2 - 2$ roots of the form (30) and at least 2 roots of the form (31) making the total number of singular
Table 7. Singular Bethe roots for $N = 12, M = 5$. There are three solutions with three 1-strings and one 2-string.

Figure 2. The energy eigenvalues for the singular solutions for $N = 500, M = 5$ with absolute value $|\lambda|$ of the form, $a_1$ or $ia_1$ of equations (30) and (31), respectively. Up to $N = 500$ we obtained only two solutions of the form $ia_1$ for every even $N \geq 10$, with $ia_1 \to 1.5i$ and $ia_1 \to 1i$, respectively for large $N$ and the corresponding eigenvalues, $E \to -2.5$ and $E \to -1.6666666666666667$, respectively as can be seen from the two isolated points in the figure.

solutions

$$N = \frac{N - 2}{2}, \quad \text{for} \quad N = 10, 12, 14, \cdots . \quad (35)$$

In figure 2, we see that for $N = 500, M = 5$, there are only two solutions of the type (31) and the rest are of the form (30) and we also checked up to $N = 500$ but find no exceptions. For $M = 6$, the following four different classes of singular solutions may exist

$$\{ \frac{i}{2}, -\frac{i}{2}, a_1, -a_1, a_2, -a_2 \} \quad \text{for} \quad a_1, a_2 \in \mathbb{R}, \quad (36)$$

$$\{ \frac{i}{2}, -\frac{i}{2}, a_1, -a_1, ia_2, -ia_2 \} \quad \text{for} \quad a_1, a_2 \in \mathbb{R}, \quad (37)$$

$$\{ \frac{i}{2}, -\frac{i}{2}, ia_1, -ia_1, ia_2, -ia_2 \} \quad \text{for} \quad a_1, a_2 \in \mathbb{R}, \quad (38)$$

$$\{ \frac{i}{2}, -\frac{i}{2}, a_1 \pm ia_2, -a_1 \pm ia_2 \} \quad \text{for} \quad a_1, a_2 \in \mathbb{R}. \quad (39)$$

In table 10 solutions of the form (36), in table 11 solutions of the form (37), in tables 12 and 14 solutions of the form (38) and in table 13 solutions of the form (39) have been displayed. A system of two variable $(x, y)$ polynomial equations for even $N \geq 12, M = 6$ can be obtained by substituting any form of the roots (36)–(39) in the Bethe Ansatz equation (6) as

$$\left( \frac{x - i}{x + i} \right)^{N - 2} = \frac{x - 3i}{x + 3i} \times \frac{x - y - 2i}{x - y + 2i} \times \frac{x + y - 2i}{x + y + 2i} ; \quad (40)$$

$$\left( \frac{y - i}{y + i} \right)^{N - 2} = \frac{y - 3i}{y + 3i} \times \frac{y - x - 2i}{y - x + 2i} \times \frac{y + x - 2i}{y + x + 2i} ; \quad (41)$$

doi:10.1088/1742-5468/2015/02/P02004
which can be rewritten as

\[
F(x, y) = \sum_{r=0}^{N-2} \left( -1 \right)^r \left[ \left( N^2 - C_{2r+1} - N^2 C_{2r} \right) x^{N-2r} + \left( 8N^2 - 2C_{2r+1} - 12N^2 C_{2r} \right) x^{N-2r} \right.
\]

\[
- \left( N^2 - C_{2r+1} + 3N^2 C_{2r} \right) y^{N-2r} \left. \right] = 0,
\]

\[
G(x, y) = \sum_{r=0}^{N-2} \left( -1 \right)^r \left[ \left( N^2 - C_{2r+1} - N^2 C_{2r} \right) y^{N-2r} + \left( 8N^2 - 2C_{2r+1} - 12N^2 C_{2r} \right) y^{N-2r} \right.
\]

\[
- \left( N^2 - C_{2r+1} + 3N^2 C_{2r} \right) y^{N-2r} \left. \right] = 0.
\]

(42)

where the pair \((x, y)\) can either be \((2a_1, 2a_2), (2a_1, 2ia_2), (2ia_1, 2ia_2), (2a_1 + 2ia_2, 2a_1 - 2ia_2)\) or \((2a_1 + 2ia_2, -2a_1 + 2ia_2)\). Note that the two equation (42) are symmetric with respect to the permutations of the variables. Although solutions of this system of equations give all the desired roots of the form (36)–(39), they also give roots such as \(x = \pm y\) and \(x \neq \pm y^* (\Re(x) = \Re(y) \neq 0)\) which are not physical solutions and therefore should be discarded. In order to calculate the number of singular solutions we have to first find out the number of solutions of (42) and subtract the number of solutions of type \(x = \pm y\) and \(x \neq \pm y^* (\Re(x) = \Re(y) \neq 0)\). According to Bernstein’s theorem [34] the number of solutions of a system of generic polynomial equations of two variables of the form

\[
f_1(x, y) = 0, f_2(x, y) = 0 \text{ in } (\mathbb{C} \setminus 0)^2 \text{ is given by their mixed area } M(\text{New}(f_1), \text{New}(f_2)),
\]

where \(\text{New}(f_1)\) and \(\text{New}(f_2)\) are the Newton polygons of \(f_1(x, y)\) and \(f_2(x, y)\), respectively. By inspecting (42) we can readily obtain the Newton polygons \(\text{New}(F(x, y))\) and

Table 10. Singular Bethe roots for \(N = 12, M = 6\). There are three solutions with four 1-strings and one 2-string.

The Minkowski sum $\text{New}(F(x, y), G(x, y))$ of the two polygons can be obtained from the multiplication of the corresponding polynomials and can be written as

\[
\text{New}(F(x, y), G(x, y)) := \text{conv}\{ (N, N), (N - 2, N), \ldots, (0, N), (N - 2, N + 2), (N - 4, N + 2), \ldots, (0, N + 2), \\
(N, N - 2), (N - 2, N - 2), \ldots, (0, N - 2), (N - 2, N), (N - 4, N), \ldots, (0, N), \\
\ldots, (N, 0), (N - 2, 0), \ldots, (0, 0), (N - 2, 2), (N - 4, 2), \ldots, (2, 2), \\
(N + 2, N - 2), (N, N - 2), \ldots, (2, N - 2), (N, N), (N - 2, N), \ldots, (2, N), \\
(N + 2, N - 4), (N, N - 4), \ldots, (2, N - 4), (N, N - 2), (N - 2, N - 2), \ldots, (2, N - 2), \\
\ldots, (N, 0), (N, 0), \ldots, (2, 0), (N, 2), (N - 2, 2), \ldots, (2, 2) \}.
\] (44)

Now one can obtain the mixed area

\[
\mathcal{M}(\text{New}(F), \text{New}(G)) = \text{Area}(\text{New}(F(x, y), G(x, y))) \\
- \text{Area}(\text{New}(F(x, y))) - \text{Area}(\text{New}(G(x, y))) = N^2,
\] (45)

which is the area of the gray colored square in figure 3. There are $2(N - 2)$ solutions of the form $x = \pm y$, which can be shown analytically easily because in this case we can reduce the Bethe ansatz equation to a one variable polynomial equation of degree $(N - 2)$. From the numerical observation for $N = 12, 14, 16$ we see that there are $4(N - 1)$ roots which are of the form $x \neq \pm y' (\Re(x) = \Re(y) \neq 0)$ and we assume this to be valid for any...
Non self-conjugate strings, singular strings and rigged configurations in the Heisenberg model

Figure 3. The Newton polygons of two polynomials $F(x, y)$ and $G(x, y)$ and their Minkowski sum is shown. The areas of the three regions are

\[
\text{Area (New (} F(x, y), G(x, y)\text{))} = N(N + 4) - 4,
\]

\[
\text{Area (New (} F(x, y)\text{))} = 2(N - 1),
\]

\[
\text{and Area (New (} G(x, y)\text{))} = 2(N - 1) \text{ and the mixed area } N^2 \text{ is given by the gray square.}
\]

For $N \geq 12$. For $N = 16, M = 6, 7$, singular solutions have been shown in table 15 and 16, respectively. So the total number of singular solutions becomes

\[
N = \frac{1}{8} (N^2 - 6N + 8) \quad \text{for} \quad N = 12, 14, \cdots.
\]

The overall factor 8 in the denominator is the multiplicity of the singular roots. Note that two roots of (42) are considered the same if upon substitution in (36)–(39) gives the same singular roots. Similarly, $M = 7$ case can also be discussed, where there are the following four different classes of singular solutions

\[
\left\{ \frac{i}{2}, -\frac{i}{2}, 0, a_1, -a_1, a_2, -a_2 \right\} \text{ for } a_1, a_2 \in \mathbb{R}, \quad (47)
\]

\[
\left\{ \frac{i}{2}, -\frac{i}{2}, 0, a_1, -a_1, ia_2, -ia_2 \right\} \text{ for } a_1, a_2 \in \mathbb{R}, \quad (48)
\]

\[
\left\{ \frac{i}{2}, -\frac{i}{2}, 0, ia_1, -ia_1, a_2, -ia_2 \right\} \text{ for } a_1, a_2 \in \mathbb{R}, \quad (49)
\]

\[
\left\{ \frac{i}{2}, -\frac{i}{2}, 0, a_1 \pm ia_2, -a_1 \pm ia_2 \right\} \text{ for } a_1, a_2 \in \mathbb{R}. \quad (50)
\]

A system of two variable $(x, y)$ polynomial equations can be obtained by substituting any of the form of the roots (47)–(50) in the Bethe Ansatz equation (6) as

\[
\left( \frac{x - i}{x + i} \right)^{N^2} = \frac{x - 3i}{x + 3i} \times \frac{x - 2i}{x + 2i} \times \frac{x - y - 2i}{x - y + 2i} \times \frac{x + y - 2i}{x + y + 2i}.
\]

\[
\left( \frac{y - i}{y + i} \right)^{N^2} = \frac{y - 3i}{y + 3i} \times \frac{y - 2i}{y + 2i} \times \frac{y - x - 2i}{y - x + 2i} \times \frac{y + x - 2i}{y + x + 2i},
\]

where $(x, y)$ has been defined in equation (42). The number of singular solutions is given by the formula (46) but now $N = 14, 16, \cdots$. Generally, for even-$N$ and even-$M$, the

\[\text{doi:10.1088/1742-5468/2015/02/P02004} \quad 17\]
for a general form of the number of singular solutions can be written as

\[ M \]

Solving this problem for the number of singular solutions becomes complicated as

\[ n = (M - 2)/2, \]

for even \( M \), \( n = (M - 3)/2 \). For odd \( M \), \( n = (M - 3)/2 \). From the analysis of singular

\[ N = \frac{1}{p_0} \left( N^n + p_1 N^{n-1} + p_2 N^{n-2} + \cdots + p_n \right) \text{ for even } N \geq 2M, \]

where the integer \( p_0 \) is the multiplicity of the singular roots, \( p_i \)'s are some integers and for even \( M, n = (M - 2)/2 \), or for odd \( M, n = (M - 3)/2 \). From the analysis of singular

\[ \text{doi:10.1088/1742-5468/2015/02/P02004} \]
solutions up to $M = 7$ we conjecture that for even $N$ the number of singular solutions for even $N$ and $M + 1$ are the same.

5. Rigged configurations

It has been observed that there is a connection between the Bethe states and the rigged configurations [35–37]. It offers a nice bijection between the Bethe states and the rigged configurations at least for a not very long spin-1/2 chain. In $N = 12$ case of the isotropic spin-1/2 chain, we establish this bijection for the singular solutions and for the non self-conjugate string solutions comparing their Takahashi quantum numbers with the riggings of a rigged configuration.

To understand what a rigged configuration is and how it works let us give a brief account of the basic idea behind the rigged configurations. We keep the notations of [35]. This is a Young Tableau-like object with two sets of integers, one on the left hand side of the boxes known as vacancy numbers $P_k(\nu)$ and the other on the right hand side of the boxes known as riggings $J_{k,\alpha}$. Consider an eigenstate of the Hamiltonian of a spin-1/2 chain of length $N$ and total $M$ down-spins in the state. The down-spins can be partitioned in different ways and each partition can be written as $\nu = \{\nu_1, \nu_2, \ldots, \nu_s\}$ such that the parts $\nu_i$ are positive integers and $s$ is the total number of parts in a particular partition.
Since all the down-spins have been partitioned in \( \nu \) it satisfies \( \sum_{i=1}^{s} \nu_i = M \). In the string-solution language, for example, \( M = 9 \) down-spins with two 3-strings, one 2-string and one 1-string have a partition \( \nu = \{3, 3, 2, 1\} \). The set of vacancy numbers \( P_k(\nu) \) which needs to be all non-negative in order to have a viable configuration are defined for a spin-1/2 system as follows

\[
P_k(\nu) = N - 2 \sum_{i=1}^{s} \min(k, \nu_i) ,
\]

where \( k = 1, 2, \cdots \) is the length of a string under consideration. Once a vacancy number is obtained then one can get a bound for the set of corresponding riggings \( J_{k, \alpha} \) as

\[
0 \leq J_{k,1} \leq J_{k,2} \leq \cdots \leq J_{k,M_k} \leq P_k(\nu) ,
\]

where \( M_k \) is the total number of \( k \)-strings in a particular set of roots defining a state. In order to have a bijection between the rigged configurations and the Bethe states we need to assign a higher value of the real part of the roots to a higher value of the riggings as

\[
\kappa(J_{k,\alpha}) = P_k(\nu) - J_{k,M_k-\alpha-1} .
\]

A rigged configuration of the form \((\nu, J)\) therefore has two different classes of configurations, one which is flip-invariant and the other which is not flip-invariant under the transformation (58).

Given a partition \( \nu \) and a set of corresponding Bethe states it is now our task to assign a rigged configuration \((\nu, J)\) to a Bethe root. One way to assign this is to make a comparison between the riggings \( J \) and the real part of the rapidities of Bethe roots and to assign a higher value of the real part of the roots to a higher value of the riggings as adopted in [35]. To get a mapping based on the comparison with the rapidity we have to then actually solve the rapidities numerically. We instead considered a comparison between the set of riggings of \( k \)-length strings \( \{J_{k,1}, J_{k,2}, \cdots, J_{k,M_k}\} \) in a form of the lexicographical order and the set of Takahashi quantum numbers of the same \( k \)-length strings \( \{I_{k}^{1}, I_{k}^{2}, \cdots, I_{k}^{M_k}\} \) in a form of the inverse lexicographical order. The comparison starts from the largest length strings to the lowest length strings in descending order. We assign larger riggings to larger Takahashi quantum numbers in the order specified in the above and obtain a bijection between the Bethe states and the rigged configurations. On the right hand side of each row of tables 1–14 we have shown the corresponding rigged configurations for \( N = 12 \) spin-1/2 chain.

To understand the mapping, let us consider all solutions of the form of one 2-string and two 1-strings in \( N = 12, M = 4 \). Since the largest string in this example is one 2-string, we first compare the Takahashi quantum numbers of the two string \( \{I_2\} = \{2, 1, 0, -1, -2\} \) with the riggings of the 2-string \( \{J_{2,1}\} = \{4, 3, 2, 1, 0\} \) from the left to the right. Then we compare 28 pairs of the Takahashi quantum numbers for two 1-strings, \( \{I_{1}^{1}, I_{1}^{2}\} = \{(7/2, 5/2), (7/2, 3/2), \cdots, (7/2, -7/2), (5/2, 3/2), (5/2, 1/2), \cdots, (5/2, -7/2), (3/2, 1/2), (3/2, -1/2), \cdots, (3/2, -7/2), (1/2, -1/2), (1/2, -3/2), (1/2, -5/2), (1/2, -7/2), (-1/2, -3/2), (-1/2, -5/2), (-1/2, -7/2), (-3/2, -5/2), (-3/2, -7/2), (-5/2, -7/2)\}, \) with 28 pairs of riggings of the two 1-strings, \( \{J_{1,1}, J_{1,2}\} = \{(6, 6), (5, 6), \cdots, (0, 6), (5, 5), (4, 5), \cdots, (0, 5), (4, 4), (3, 4), \cdots, (0, 4), (3, 3), (2, 3), (1, 3), (0, 3), (2, 2), (1, 2), (0, 2), (1, 1), (0, 1), (0, 0)\} \) from the left to the right. Four such explicit correspondences have been given in [35].
6. Conclusions

We have observed that in the isotropic spin-1/2 Heisenberg model there are some string solutions which do not fall into the standard category of string solutions. These are physical solutions of the Bethe ansatz equations where the central rapidity of some of the odd length strings in a given Bethe state becomes complex contrary to the standard knowledge where the central rapidity of an odd-length string is considered to be real even in the deformed strings. Some of the individual strings in a Bethe state in such scenarios are no longer self-conjugate, but collectively all the strings in the Bethe state remain self-conjugate. This behavior starts from $N = 12$ case, where we see that in a $M = 5$ down spin sector the central rapidity of one of the two 1-strings and the central rapidity of a 3-string become complex conjugate to each other as shown in table 1. In $M = 6$ down spin sector with $M_1 = M_2 = M_3 = 1$ we also observed that the central rapidity of a 1-string and the central rapidity of a 3-string become complex conjugate, which are shown in table 2. To obtain these types of solutions in the string picture, we have used the Newton-Raphson method in Mathematica and have made use of the roots of the Takahashi string with some modifications as the initial guess for the input in the iteration method. The number of missing solutions in the deformed string picture for large $N$ is solely attributed to the collapse of pairs of strings in [20] but as we observe in our analysis the missing string solutions include not only the collapsing strings but also the non self-conjugate strings. Note that if one allows large deviations then the non self-conjugate strings, which we investigated in this paper, can always be arranged in such a way that the individual strings become self-conjugate. For example, any complex solution can be written in terms of a combination of 1-strings and 2-strings, because complex rapidities always appear in complex conjugate pairs. In some cases, it is even possible to arrange the non self-conjugate string solutions in terms of self-conjugate strings involving larger than 2-strings. However, we instead opted for a non self-conjugate string arrangement for the following reason: We constructed all the solutions as small deformations of the pure string solutions so that we can use the roots of the pure string solutions as an initial guess in the iteration process. According to our investigations, if we introduce the pure string solutions as the initial guess, it is relatively easy to find out the small deviations in the iteration method. In the string hypothesis in the limit that the small deviations vanish, we obtain the Takahashi quantum numbers, which have unique one-to-one correspondence with the not collapsing string solutions. In our examples of non self-conjugate string solutions mentioned in tables 1 and 2 we emphasize this unique correspondence of the Takahashi quantum numbers (shown in the third column from the left) to the non self-conjugate string solutions. Just to clarify the point, let us consider the first solution of table 1, which is composed of one real 1-string $(0.180\,714\,318\,631\,830\,55)$, one complex 1-string $(0.444\,763\,506\,448\,639\,27 - 0.018\,770\,199\,402\,377\,38i)$ and one 3-string $(0.491\,814\,213\,695\,899\,34 + 0.961\,471\,132\,379\,080\,9i, 0.444\,763\,506\,448\,639\,27 + 0.018\,770\,199\,402\,377\,38i, 0.491\,814\,213\,695\,899\,34 - 0.961\,471\,132\,379\,080\,9i)$ with a complex
Non self-conjugate strings, singular strings and rigged configurations in the Heisenberg model

center. Once we take the $\Delta_{\alpha\beta} \to 0$ limit, we recover the Takahashi quantum numbers associated with them, which are also derived directly by making use of equation (11). On the other hand, if one arranges the above mentioned solution in the form of one 1-string $(0.18071431863183055)$ and two 2-strings $(0.49181421369589934 + 0.9614711323790809i, 0.49181421369589934 - 0.9614711323790809i)$ and $(0.44476350644863927 + 0.01877019940237738i, 0.44476350644863927 - 0.01877019940237738i)$ with large deviations, then the self-conjugacy is restored for each individual string, while there is no set of Takahashi quantum numbers available for this arrangement in the string picture. Here, we recall from our studies that without Takahashi quantum numbers we do not have any good initial guess in the iteration method of finding the solutions to the Bethe ansatz equations, while the solution of the Takahashi equations for a given set of Takahashi quantum numbers leads to a good initial guess. The same is true if one arranges the above solution in the form of one 1-string $(0.18071431863183055)$ and one 4-string $(0.49181421369589934 + 0.9614711323790809i, 0.44476350644863927 + 0.01877019940237738i, 0.44476350644863927 - 0.01877019940237738i, 0.49181421369589934 - 0.9614711323790809i)$ with large deviations. Similarly, every non self-conjugate solution we have shown in this paper is given in the unique arrangement that is mapped to a set of the Takahashi quantum numbers.

Considering the sum of the rapidities of a singular Bethe state to be zero for even-length spin chains we have classified the singular roots and obtained a general form of the rapidities. For $M = 4, 5$ it enables us to reduce the Bethe ansatz equations to a polynomial equation of one variable, which can be easily handled numerically for large even $N$ of the spin chain. We showed that for $M = 4$ and $M = 5$ there are at most $\mathcal{N} = (N - 2)/2$ singular solutions for $N \geq 2M$. For $M = 6, 7$ it is possible to reduce the Bethe ansatz equations to a system of polynomial equations of two variables. Making use of the algebraic method we showed that the number of singular solutions in such cases are at most $\mathcal{N} = (N^2 - 6N + 8)/8$. For generic values of even $N$ and even $M$ we can not give the number of singular solutions present but we can predict a form of the formula (55) for the number of singular solutions with coefficients yet to be determined. Our analysis on the number of singular solutions agrees with the value $\frac{N^2}{2} - M^2$ for even $M$ and $M + 1$, which is one of the conjectures in [35]. However, we showed with examples that the number of singular solutions for even-$M$ and $M + 1$ are the same at least up to $M = 6$, which disagrees with the conjecture 11(C) of [35] and there is no forbidden rigging in connection with the singular solutions in the $N = 12$ spin chain. The eigenvalues for the singular states have been obtained by making use of the regularization scheme of [10, 27, 28, 36]. The detailed derivation of the eigenvalues and the eigenstates for the singular solutions have been given in [38], where we made use of the same regularization scheme.
