Maximising Neumann eigenvalues on rectangles

M. van den Berg ¹

K. Gittins ³

27 May 2016

Abstract

We obtain results for the spectral optimisation of Neumann eigenvalues on rectangles in \( \mathbb{R}^2 \) with a measure or perimeter constraint. We show that the rectangle with measure 1 which maximises the \( k \)'th Neumann eigenvalue converges to the unit square in the Hausdorff metric as \( k \to \infty \). Furthermore, we determine the unique maximiser of the \( k \)'th Neumann eigenvalue on a rectangle with given perimeter.

AMS 2000 subject classifications. 35J20, 35P99.

Key words and phrases. Spectral optimisation, Neumann eigenvalues.

1 Introduction

Let \( \Omega \) be an open or quasi-open set in Euclidean space \( \mathbb{R}^m \) \((m = 2, 3, \ldots)\), with boundary \( \partial \Omega \), and let \( -\Delta_\Omega \) be the Dirichlet Laplacian acting in \( L^2(\Omega) \). It is well known that if \( \Omega \) has finite Lebesgue measure \( |\Omega| \) then \( -\Delta_\Omega \) has compact resolvent, and the spectrum of \( -\Delta_\Omega \) is discrete and consists of eigenvalues \( \lambda_1(\Omega) \leq \lambda_2(\Omega) \leq \ldots \) with \( \lambda_j(\Omega) \to \infty \) as \( j \to \infty \). The problem of minimising the eigenvalues of the Dirichlet Laplacian over sets in \( \mathbb{R}^m \) with a geometric constraint has been studied extensively. For example it was shown in [10] and [21] that for any \( k \in \mathbb{N} \) the minimisation problem

\[
\inf \{ \lambda_k(\Omega) : \Omega \text{ quasi-open in } \mathbb{R}^m, \ |\Omega| = c \} \tag{1.1}
\]

has a bounded minimiser with finite perimeter. The celebrated Faber-Krahn and Krah-Szego inequalities assert that these minimisers are a ball with measure \( c \) for \( k = 1 \) and the union of two disjoint balls each with measure \( c/2 \) for \( k = 2 \) respectively, see [17]. It has been conjectured that if \( m = 2, k = 3 \) the disc with measure \( c \) is a minimiser. Less is known for higher values of \( k \). For \( m = 2, k \geq 5 \), it was shown in [8] that neither the disc nor a disjoint union of discs is optimal. In addition, numerical experiments indicate as to what the minimisers look like see [22, 2]. Some bounds on the number of components of minimisers of (1.1) have been obtained in [7].

Other constraints than the measure have been considered in [12], [15], [13] and [6]. For example, it was shown in [15] that a minimiser exists for the \( k \)'th Dirichlet eigenvalue under the constraint that the

³School of Mathematics, University of Bristol, University Walk, Bristol BS8 1TW, United Kingdom. kg13951@bristol.ac.uk
perimeter is fixed and the measure is finite. Existence in the planar case is particularly straightforward, since elements of minimising sequences are convex and bounded uniformly in \( k \). The latter fact allowed Bucur and Freitas to show in [13] that there exists a sequence of translates of these minimisers which converges to the disc in the Hausdorff metric. This phenomenon of an asymptotic shape has been established for a wide class of constraints in [6]. However, this class does not include the original measure constraint.

Numerical experiments have also been carried out to investigate the optimisation of Dirichlet eigenvalues subject to a perimeter constraint, see [3] and [9]. These papers use different methods to obtain insight as to what the optimal shapes would look like. The asymptotic behaviour of the \( k \)-th optimal eigenvalue on \( m \)-dimensional cuboids (rectangular parallelepipeds) with a perimeter constraint was analysed in [3].

In [14] it was shown that the infimum in (1.1) with \( c = 1 \) behaves like \( 4\pi^2 k^2 \omega_m^{- \frac{2}{m}} \) as \( k \to \infty \) provided the Pólya conjecture for Dirichlet eigenvalues holds. That is for every bounded open set \( \Omega \subset \mathbb{R}^m \), \( \lambda_k(\Omega) \geq 4\pi^2 (|\Omega| \omega_m)^{- \frac{2}{m}} k^2 \), where \( \omega_m \) is the measure of the ball in \( \mathbb{R}^m \) with radius 1.

In a recent paper, [1], Antunes and Freitas proved the following asymptotic shape result with a measure constraint. For \( a \geq 1 \), let

\[
R_a = \{(x_1, x_2) : 0 < x_1 < a, 0 < x_2 < a^{-1}\}
\]

be a rectangle with measure 1. The infimum of the variational problem

\[
\lambda_k^* := \inf \{\lambda_k(R_a)\}
\]

is achieved for some \( a_k^* \geq 1 \), and \( \lim_{k \to \infty} a_k^* = 1 \).

A heuristic explanation for this asymptotic shape result is the following (see [1]). For any rectangle in \( \mathbb{R}^2 \) with measure \( |R| \) and perimeter \( \text{Per}(R) \) one has that

\[
\lambda_k(R) = \frac{4\pi k}{|R|} + \frac{2\pi^{1/2}\text{Per}(R)k^{1/2}}{|R|^{3/2}} + o(k^{1/2}), \quad k \to \infty. \tag{1.2}
\]

So if \( |R| = 1 \) then (1.2) suggests that the rectangle which minimises \( \lambda_k(R) \), \( k \to \infty \) is the one with minimal perimeter, i.e. the unit square. The main part of the proof in [1] is to show that the \( a_k^* \)'s are uniformly bounded. It is then possible to use well-known number theoretic results for the number of lattice points inside ellipses where the ratio of the axes remains bounded.

The asymptotic formula (1.2) holds true for a wide class of planar domains with a smooth boundary which satisfy a billiard condition. This suggests that the asymptotic shape with fixed measure is a disc. The proof of this seems well beyond reach, even if an additional convexity constraint is imposed, [6].

In this paper we consider the maximisation of Neumann eigenvalues. It is well known that if \( \Omega \) is an open, bounded and connected set in \( \mathbb{R}^m \) with Lipschitz boundary then the spectrum of the Neumann Laplacian is discrete and consists of eigenvalues \( \mu_0(\Omega) < \mu_1(\Omega) \leq \mu_2(\Omega) \leq \ldots \) accumulating at infinity. The first Neumann eigenvalue has multiplicity 1 and \( \mu_0(\Omega) = 0 \). Szegö and Weinberger showed that \( \mu_1(\Omega) \leq \mu_1(\Omega^*) \), where \( \Omega^* \) is the ball with the same measure as \( \Omega \), see [17]. It was shown in [16] that the union of two disjoint planar discs, each with measure \( c/2 \), achieves the supremum of \( \mu_2(\Omega) \) in the class of simply connected sets in \( \mathbb{R}^2 \) with measure \( c \). Nothing is known about the existence of maximisers for higher \( k \) (see for instance [11, Section 7.4]). In this paper we consider the problem of maximising the \( k \)-th Neumann eigenvalue over all rectangles in \( \mathbb{R}^2 \) with fixed measure, and study the asymptotic behaviour as \( k \to \infty \).

Our main result is the following.

**Theorem 1.1**  
(i) Let \( k \in \mathbb{N} \). The variational problem

\[
\mu_k^* := \sup \{\mu_k(R_b) : b \geq 1\}
\]

has a maximising rectangle \( R_b \) with \( b = b_k^* \).
(ii) Any sequence of optimal rectangles \( (R_k) \) converges in the Hausdorff metric to the unit square as \( k \to \infty \). Moreover there exists \( \theta \in \left(\frac{1}{2}, 1\right) \) such that for \( k \to \infty \),

\[
b_k^* = 1 + O(k^{(\theta - 1)/4}). \tag{1.4}
\]

(iii) Let \( \mu_k^* = \mu_k(R_k) \). Then

\[
\mu_k^* = 4\pi k - 8(\pi k)^{1/2} + O(k^{(\theta + 1)/4}), \quad k \to \infty. \tag{1.5}
\]

The exponent \( \theta \) shows up in the remainder of Gauss’ circle problem. It is known that for any \( \epsilon > 0 \), (see the Introduction in [19])

\[
\theta = \frac{131}{208} + \epsilon.
\]

The table below shows that the maximising rectangles for \( k = 4, 6, 10 \) and \( k = 15 \) are not unique. The eigenvalues of the rectangle \( R_b \) are of the form

\[
\mu_{p,q} = \frac{\pi^2 p^2}{b^2} + \pi^2 q^2 b^2, \tag{1.6}
\]

for \( p, q \in \mathbb{Z}^+ = \mathbb{N} \cup \{0\} \). The ordered list of real numbers \( \{\mu_{p,q} : p \in \mathbb{Z}^+, q \in \mathbb{Z}^+\} \) are the eigenvalues \( \{0 = \mu_0(R_b) < \mu_1(R_b) \leq \mu_2(R_b) \leq \ldots \} \) of the Neumann Laplacian on \( R_b \). From the proof of Theorem 1.1(ii) we will see that the maximised \( k \)’th eigenvalue has multiplicity at least 2. In the table below we list the values of \( \mu_k^* \) for \( k = 1, \ldots, 15 \) as well as the \( b_k^* \) and the pairs of maximising modes which realise this maximum.

| \( k \) | \( \mu_k^* \) | \( b_k^* \) | maximising pair of modes |
|---|---|---|---|
| 1 | \( \pi^2 \) | 1 | (1, 0), (0, 1) |
| 2 | \( 2\pi^2 \) | \( \sqrt{2} \) | (2, 0), (0, 1) |
| 3 | \( 3\pi^2 \) | \( \sqrt{3} \) | (3, 0), (0, 1) |
| 4 | \( 4\pi^2 \) | 2 or 1 | (4, 0), (0, 1) or (2, 0), (0, 2) |
| 5 | \( 5\pi^2 \) | \( \sqrt{5} \) | (5, 0), (0, 1) |
| 6 | \( 6\pi^2 \) | \( \sqrt{6} \) or \( \frac{1}{2}\sqrt{6} \) | (6, 0), (0, 1) or (3, 0), (0, 2) |
| 7 | \( 7\pi^2 \) | \( \sqrt{7} \) | (7, 0), (0, 1) |
| 8 | \( \frac{18\sqrt{3}}{5}\pi^2 \) | \( \frac{\sqrt{5}}{\sqrt{2}} \) | (2, 2), (3, 0) |
| 9 | \( \frac{16\sqrt{3}}{5}\pi^2 \) | \( \frac{2\sqrt{5}}{\sqrt{5}} \) | (4, 1), (0, 2) |
| 10 | \( 10\pi^2 \) | \( \frac{1}{2}\sqrt{10} \) or \( \sqrt{10} \) | (5, 0), (0, 2) or (10, 0), (0, 1) |
| 11 | \( 12\pi^2 \) | \( \frac{2}{\sqrt{2}} \sqrt{3} \) | (4, 0), (0, 3) |
| 12 | \( \frac{27}{30}\sqrt{10}\pi^2 \) | \( \frac{3}{\sqrt{5}} \) | (1, 3), (3, 2) |
| 13 | \( 8\sqrt{3}\pi^2 \) | \( 3^{1/4} \sqrt{2} \) | (6, 1), (0, 2) |
| 14 | \( 15\pi^2 \) | \( \frac{1}{2}\sqrt{15} \) | (5, 0), (0, 3) |
| 15 | \( 16\pi^2 \) | 2 or 1 | (8, 0), (0, 2) or (4, 0), (0, 4) |

We also see in the table above that the unit square is a maximiser for \( k = 1, 4 \) and \( k = 15 \). We conjecture that the unit square is a maximiser if the maximising pair of modes are given by \((2^n, 0), (0, 2^n) : n \in \mathbb{Z}^+\). This gives that the unit square is a maximiser for \( \mu_k \) if

\[
k = \sum_{l \in \mathbb{Z}^+} [(4^n - l^2)^{1/2}] + 2^n - 1, \quad n \in \mathbb{Z}^+.
\]

The heuristic explanation of (1.4) is that for Neumann eigenvalues on a rectangle \( R \subset \mathbb{R}^2 \),

\[
\mu_k(R) = \frac{4\pi k}{|R|} - \frac{2\pi^{1/2}\text{Per}(R)k^{1/2}}{|R|^{3/2}} + o(k^{1/2}), \quad k \to \infty,
\]
so that the maximising rectangle with measure $|R|$ is the one which minimises its perimeter, i.e. the square with measure $|R|$.

The key ingredient in the proof of (1.4) in Section 2 below is to show that $\limsup_{k \to \infty} b^*_k < \infty$. This is more involved than the corresponding proof of Antunes and Freitas that $\limsup_{k \to \infty} a_k^* < \infty$ for the minimising rectangles of the Dirichlet eigenvalues. In particular, it requires an a-priori bound on $\limsup b^*_k/k^{1/2}$ with some constant which, for technical reasons, has to be sufficiently small. This is achieved in Lemma 2.3. The number theoretical estimates are also more involved, and will be given in Lemma 2.2.

In Section 3, we turn our attention to the optimisation of Neumann eigenvalues on rectangles with a perimeter constraint. Generally, these problems are not well-posed (see Section 3 for a discussion). Thus, we consider the following variational problems

$$\sup\{\mu_k(R) : R \text{ rectangle}, \ Per(R) = 4\}, \quad (1.7)$$

and

$$\inf\{\mu_k(R) : R \text{ rectangle}, \ Per(R) = 4\}. \quad (1.8)$$

In Section 3.1, we consider problem (1.7) and we prove that for $k \in \mathbb{N}$, there is a unique maximising rectangle for $\mu_k$ which collapses to a segment as $k \to \infty$. In Section 3.2, we show that for $k = 1$ problem (1.8) does not have a solution, while for $k \geq 2$ it does and any sequence of minimising rectangles converges to the unit square in the sense of Hausdorff as $k \to \infty$.

## 2 Proof of Theorem 1.1

**Proof of Theorem 1.1(i).** Fix $k \in \mathbb{N}$. Suppose that $\{R_{b(\ell)}\}_{\ell \in \mathbb{N}}$ is a maximising sequence for $\mu_k$ such that $b(\ell) \to \infty$ as $\ell \to \infty$. Then, for sufficiently large $\ell$,

$$\mu_k(R_{b(\ell)}) = \frac{\pi^2 k^2}{(b(\ell))^2},$$

and so $\mu_k(R_{b(\ell)}) \to 0$ as $\ell \to \infty$. On the other hand, we have that $b = 1$ for a square and so $\mu_k \geq \pi^2 > 0$. This contradicts the assumption that $\{R_{b(\ell)}\}_{\ell \in \mathbb{N}}$ is a maximising sequence for $\mu_k$. Thus any maximising sequence $\{R_{b(\ell)}\}_{\ell \in \mathbb{N}}$ for $\mu_k$ is such that $b(\ell)$ remains bounded. Hence there exists a convergent subsequence, again denoted by $b(\ell)$, such that $b(\ell) \to b^*_k$ for some $b^*_k \in [1, \infty)$. Since $b \mapsto \mu_k(R_b)$ is continuous, $\mu_k(R_{b(\ell)}) \to \mu_k(R_{b^*_k})$ as $\ell \to \infty$. Hence $R_{b^*_k}$ is a maximiser.

In order to prove Theorem 1.1(ii) we need three lemmas which will be given below.

**Lemma 2.1** Let $\nu_k = \mu_k(R_1)$ be the $k$'th positive Neumann eigenvalue for the unit square in $\mathbb{R}^2$. Then

$$\nu_k \geq 4\pi k - 16(\pi k)^{1/2}, \ k \geq 1. \quad (2.1)$$

**Proof.** The cases $k = 1, 2, \ldots, 5$ hold true by direct computation. Let us assume that $k \geq 6$. For the unit square we have by (2.3) that

$$N(\nu; 1) = 2 \left\lfloor \frac{\nu^{1/2}}{\pi} \right\rfloor + \{ (x, y) \in \mathbb{N}^2 : x^2 + y^2 \leq \nu/\pi^2) \}.$$  

Let $\nu > 2$. For each lattice point in $\mathbb{N}^2$ (i.e. $x \geq 1, y \geq 1$) satisfying $x^2 + y^2 \leq \nu/\pi^2$ there exists an open lower left-hand square with vertices $(x, y), (x - 1, y), (x - 1, y - 1), (x, y - 1)$ inside the quarter circle with radius $\nu^{1/2}/\pi$ in the first quadrant. Hence

$$N(\nu; 1) \leq \frac{\nu}{4\pi} + \frac{2\nu^{1/2}}{\pi}.$$  

So for $\nu = \nu_k$ we have that

$$k \leq \frac{\nu_k}{4\pi} + \frac{2\nu_k^{1/2}}{\pi}. \quad (2.2)$$
We note that (2.2) also holds in case \( \nu_k \) has multiplicity larger than 1. Since the unit square tiles \( \mathbb{R}^2 \), we have by Pólya's Inequality, [23], that \( \nu_k \leq 4\pi k \). Hence

\[
k \leq \frac{\nu_k}{4\pi} + \frac{2(4\pi k)^{1/2}}{\pi}.
\]

This implies (2.1).

**Lemma 2.2** For all \( \mu > 0, b > 0 \), define the counting function

\[
N(\mu; b) = \left\{ (x, y) \in (\mathbb{Z}^+)^2 \setminus \{(0, 0)\} : \frac{\pi^2 x^2}{b^2} + \pi^2 b^2 y^2 \leq \mu \right\}.
\] (2.3)

Then for all \( \mu > 0, b > 0 \) with \( \frac{\mu^{1/2}}{b^2} \geq 2 \) we have that

\[
N(\mu; b) \geq \frac{\mu}{4\pi} + \frac{b\mu^{1/2}}{2\pi} - \frac{b^{3/2} \mu^{1/4}}{(2\pi)^{1/2}} - 1.
\] (2.4)

To prove Lemma 2.2, we obtain a lower bound for the number of integer lattice points in \( \mathbb{N}^2 \) which are inside or on the ellipse

\[
E(\mu) = \left\{ (x, y) \in \mathbb{R}^2 : \frac{\pi^2 x^2}{b^2} + \pi^2 b^2 y^2 \leq \mu \right\}.
\]

**Proof.** For each \( (x, y) \in E(\mu) \), we have that

\[
x \leq \frac{b}{\pi} (\mu - \pi^2 b^2 y^2)^{1/2} = b^2 \left( \frac{\mu}{\pi^2 b^2} - y^2 \right)^{1/2}.
\]

Then

\[
N(\mu; b) = \left[ \frac{\mu^{1/2}}{\pi b} \right] + \left[ \frac{b \mu^{1/2}}{\pi} \right] + \sum_{y \in \mathbb{N}} \left[ b^2 \left( \frac{\mu}{\pi^2 b^2} - y^2 \right)^{1/2} \right] \\
\geq \left[ \frac{\mu^{1/2}}{\pi b} \right] + \left[ \frac{b \mu^{1/2}}{\pi} \right] + \sum_{y=1}^{\left\lfloor \mu^{1/2}/(\pi b) \right\rfloor} \left[ b^2 \left( \frac{\mu}{\pi^2 b^2} - y^2 \right)^{1/2} \right] \\
= \left[ \frac{b \mu^{1/2}}{\pi} \right] + b^2 \sum_{y=1}^{\left\lfloor \mu^{1/2}/(\pi b) \right\rfloor} \left( \frac{\mu}{\pi^2 b^2} - y^2 \right)^{1/2}.
\]

Let \( R = \frac{\mu^{1/2}}{\pi b} \) and define \( f(y) := (R^2 - y^2)^{1/2}, 0 \leq y \leq R \). Then \( \sum_{y=1}^{\left\lfloor R \right\rfloor} (R^2 - y^2)^{1/2} \) is the area of the rectangles which are inscribed in the first quadrant of the circle of radius \( R \). Hence, we can re-write this as

\[
\sum_{y=1}^{\left\lfloor R \right\rfloor} (R^2 - y^2)^{1/2} = \frac{\pi R^2}{4} - A,
\] (2.5)

where

\[
A = \sum_{n=0}^{\left\lfloor R \right\rfloor - 1} \int_n^{n+1} (f(y) - f(n+1)) dy + \int_{\left\lfloor R \right\rfloor}^R f(y) dy.
\] (2.6)
Since \(|R| \leq y \leq R\) we have that
\[
\int_{[R]} f(y) \, dy = \int_{[R]} (R - y)^{1/2}(R + y)^{1/2} \, dy \\
\leq (2R)^{1/2} \int_{[R]} (R - y)^{1/2} \, dy \\
= \frac{2}{3}(R - |R|)^{3/2}(2R)^{1/2}.
\]
(2.7)

Since \(f\) is decreasing and concave we have that
\[
f(y) \leq f(n) + (y - n)f'(n), \quad n \leq y \leq n + 1.
\]

Hence
\[
\sum_{n=0}^{\lfloor R \rfloor - 1} \int_{n}^{n+1} (f(y) - f(n + 1)) \, dy \leq f(0) - f(\lfloor R \rfloor) + \frac{1}{2} \sum_{n=0}^{\lfloor R \rfloor - 1} f'(n).
\]
(2.8)

Since
\[
f'(y) = -\frac{y}{(R^2 - y^2)^{1/2}},
\]
f'(0) = 0, and \(y \mapsto -f'(y)\) is increasing, we have that
\[
\frac{1}{2} \sum_{n=0}^{\lfloor R \rfloor - 1} f'(n) \leq \frac{1}{2} \int_{0}^{\lfloor R \rfloor - 1} f'(y) \, dy = \frac{1}{2}(f(\lfloor R \rfloor - 1) - f(0)).
\]
(2.9)

By (2.5)-(2.7), (2.8), and (2.9)
\[
\sum_{y=1}^{\lfloor R \rfloor} (R^2 - y^2)^{1/2} \geq \frac{\pi R^2}{4} - \frac{R}{2} + (R^2 - \lfloor R \rfloor^2)^{1/2} - \frac{1}{2}(R^2 - (\lfloor R \rfloor - 1)^2)^{1/2} - \frac{2}{3}(R - \lfloor R \rfloor)^{3/2}(2R)^{1/2}.
\]

Next note that
\[
\frac{1}{2}(R^2 - (\lfloor R \rfloor - 1)^2)^{1/2} \leq \frac{1}{2}(R - \lfloor R \rfloor + 1)^{1/2}(2R)^{1/2},
\]
and that for \(R \geq 2\),
\[
(R^2 - \lfloor R \rfloor^2)^{1/2} \geq (R - \lfloor R \rfloor)^{1/2}\frac{R + \lfloor R \rfloor}{2R} \left(\frac{R}{(2R)^{1/2}}\right)^{1/2} (2R)^{1/2} \geq \frac{5}{6}(R - \lfloor R \rfloor)^{1/2}(2R)^{1/2}.
\]

Let \(\theta = R - \lfloor R \rfloor \in [0, 1]\) and define \(g : [0, 1] \mapsto \mathbb{R}\) by
\[
g(\theta) = -\left(\frac{5}{6}\right)^{1/2} \theta^{1/2} + \frac{1}{2}(\theta + 1)^{1/2} + \frac{2}{3} \theta^{3/2}.
\]

Then
\[
g''(\theta) = \frac{1}{4} \left(\frac{5}{6}\right)^{1/2} \theta^{-3/2} - \frac{1}{8}(\theta + 1)^{-3/2} + \frac{1}{2} \theta^{-1/2} > 0,
\]
and so \(g\) is convex. Hence \(g(\theta) \leq \max\{g(0), g(1)\} = \frac{1}{2}\). So for \(R = \frac{\mu^{1/2}}{\pi b} \geq 2\) we have that
\[
N(\mu; b) \geq \frac{b\mu^{1/2}}{\pi} + b^2 \left(\frac{\pi R^2}{4} - \frac{R}{2} - R^{1/2}/2\right) \\
= \frac{b\mu^{1/2}}{\pi} + \frac{\mu}{4\pi} - \frac{b\mu^{1/2}}{2\pi} - \frac{b^{3/2}\mu^{1/4}}{(2\pi)^{1/2}} \\
\geq \frac{\mu}{4\pi} + \frac{b\mu^{1/2}}{2\pi} - \frac{b^{3/2}\mu^{1/4}}{(2\pi)^{1/2}} - 1.
\]
(2.10)
Below we obtain an a-priori upper bound on the longest side $b^*_k$ of a maximising rectangle in terms of $k$.

**Lemma 2.3**

$$\limsup_{k \to \infty} \frac{b^*_k}{k^{1/2}} \leq 0.46359.$$  \hfill (2.11)

**Proof.** Define $c_k := \frac{b^*_k}{k^{1/2}}$. We shall bound $c_k$ using the maximality of $\mu^*_k$ at $R_{b^*_k}$. We first note that

$$\limsup_{k \to \infty} c_k \leq \left(\frac{\pi}{4}\right)^{1/2}.$$  \hfill (2.12)

Indeed, we know by (1.6) that the eigenvalues of $R_{b^*_k}$ are of the form

$$\mu_{p,q} = \frac{\pi^2 p^2}{c_k^2} + \pi^2 q^2 c_k^2 k,$$

for $p, q \in \mathbb{Z}^+$. Choosing the pairs $(p, q)$ in (1.6) as $(0, 0), (1, 0), \ldots, (k, 0)$ we get that

$$\frac{\pi^2 k^2}{c_k^2} \geq \mu^*_k \geq \nu_k.$$

This gives by Lemma 2.1 that for $k \geq 3$,

$$c_k^2 \leq \frac{\pi^2 k}{4\pi k - 16(\pi k)^{1/2}},$$

which passing to the limit leads to (2.12).

Assume now that for some $k$ (large), all of the eigenvalues of $R_{b^*_k}$ up to index $k$ are given by the pairs $(p, q) = (0, 0), (1, 0), \ldots, (k, 0)$. If this is the case, we see that $\mu^*_k$ has to be (at least) double, and hence equal to some value of the form

$$\frac{\pi^2 p^2}{c_k^2} + \pi^2 q^2 c_k^2 k$$

for some $q \geq 1$. Indeed, if it is not double, then being simple, for a small variation of $b$ around $b^*_k$ it continues to be simple and we can perform the derivative of the mapping

$$b \mapsto \mu_k(R_b),$$

in $b^*_k$. This derivative equals $-\frac{2\pi^2 k^2}{(b^*_k)^3}$ which is not vanishing, in contradiction with the optimality of $b^*_k$.

So, either the first $k + 1$ eigenvalues are not given by $(p, q) = (0, 0), (1, 0), \ldots, (k, 0)$, or the value of $\mu^*_k$ is equal to some $\frac{\pi^2 p^2}{c_k^2} + \pi^2 q^2 c_k^2 k$, for $q \geq 1$. In both cases there exists some $p$ such that one of the first $k + 1$ eigenvalues is given by $(p, 1)$. Let $\bar{p}$ be the smallest number such that

$$\frac{\pi^2 \bar{p}^2}{c_k^2} + \pi^2 \bar{p}^2 c_k^2 k \geq 4\pi k - 16(\pi k)^{1/2},$$  \hfill (2.13)

and $(\bar{p}, 1)$ does not produce an eigenvalue of the list $\mu_0(R_{b^*_k}), \ldots, \mu_k(R_{b^*_k})$.

Then all eigenvalues given by the pairs $(0, 1), \ldots, (\bar{p} - 1, 1)$ belong to the list $\mu_0(R_{b^*_k}), \ldots, \mu_k(R_{b^*_k})$. Now, we consider the eigenvalues given by the pairs

$$(0, 0), (1, 0), \ldots, (k - \bar{p} + 1, 0).$$
We conclude that the eigenvalue given by the last pair \((k-\bar{p}+1,0)\) is not smaller than \(\mu_k^*\). Consequently
\[
\frac{\pi^2(k-\bar{p}+1)^2}{c_k^2 k} \geq \mu_k^* \geq 4\pi k - 16(\pi k)^{1/2}.
\] (2.14)

From (2.13) and (2.14) we get, respectively
\[
\pi \bar{p} \geq c_k(4\pi k^2 - 16\pi^{1/2}k^{3/2} - \pi^2 c_k^2)^{1/2}
\]
\[
\pi(k - \bar{p} + 1) \geq c_k(4\pi k^2 - 16\pi^{1/2}k^{3/2})^{1/2}.
\]

Adding the two inequalities, dividing by \(k\) and passing to the limit for \(k \to \infty\), we obtain that, for any limit point \(\alpha \in [0, (\pi/4)^{1/2}]\) of the sequence \((c_k)_k\),
\[
\pi \geq \alpha((4\pi)^{1/2} + (4\pi - \pi^2 \alpha^2)^{1/2}).
\]

A numerical evaluation, gives that \(\alpha \in [0, 0.46359]\). \(\square\)

We now prove that \(\limsup b_k^* < \infty\). Since (2.10) holds for all pairs \((\mu, b)\), it must also hold for all optimal pairs \((\mu_k^*, b_k^*)\). Furthermore we note that \(\mu \mapsto N(\mu; b)\) is increasing. Then, \(\mu_k^*\) being optimal and having finite multiplicity, we have for all \(\epsilon \in (0, \nu_1)\) that
\[
k - 1 \geq N(\mu_k^* - \epsilon; b_k^*) \geq N(\nu_k - \epsilon; b_k^*).
\]

By Lemma 2.1 and Lemma 2.3 we have that for all \(\epsilon > 0\) sufficiently small
\[
\limsup_{k \to \infty} \frac{(\nu_k - \epsilon)^{1/2}}{\pi b_k^*} \geq 2.
\]

So invoking Lemma 2.2, for all \(k\) sufficiently large, we obtain that
\[
k - 1 \geq N(\nu_k - \epsilon; b_k^*) \geq \frac{\nu_k - \epsilon}{4\pi} + \frac{b_k^*(\nu_k - \epsilon)^{1/2}}{2\pi} - \frac{(b_k^*)^{3/2} (\nu_k - \epsilon)^{1/4}}{(2\pi)^{1/2}} - 1.
\]

Rearranging terms we have that
\[
\frac{4\pi k - \nu_k + \epsilon}{(\nu_k - \epsilon)^{1/2}} \geq 2b_k^*(1 - (2\pi b_k^*)^{1/2} (\nu_k - \epsilon)^{-1/4}).
\] (2.15)

By Lemma 2.1 we conclude that
\[
\limsup_{k \to \infty} (\nu_k - \epsilon)^{-1/2} (4\pi k - \nu_k + \epsilon) \leq 8.
\] (2.16)

On the other hand Lemma 2.3 gives that
\[
\liminf_{k \to \infty} (1 - (2\pi b_k^*)^{1/2} (\nu_k - \epsilon)^{-1/4}) \geq 1 - \pi^{1/4}(0.46359)^{1/2}.
\] (2.17)

Putting (2.15), (2.16) and (2.17) together gives that
\[
\limsup_{k \to \infty} b_k^* \leq \frac{4}{1 - \pi^{1/4}(0.46359)^{1/2}} \leq 43.
\] (2.18)

Proof of Theorem 1.1(ii). Let
\[
N_0(\mu; b) = \left\{(x, y) \in \mathbb{R}^2 : \frac{\pi^2 x^2}{b^2} + \pi^2 y^2 \leq \mu\right\}.
\]

Then
\[
N(\mu; b) = \frac{1}{4} N_0(\mu; b) + \frac{1}{2} \left[\frac{b_k^{1/2}}{\pi}\right] + \frac{1}{2} \left[\frac{\mu^{1/2}}{\pi b}\right] - \frac{1}{4}.
\] (2.19)
We apply the identity above to the optimal pair \((b_k^*, \mu_k^*)\), and obtain that if \(\mu_k^*\) has multiplicity \(\Theta_k\), then

\[
k + \Theta_k - 1 = N(\mu_k^*; b_k^*) = \frac{1}{4} N_0(\mu_k^*; b_k^*) + \left( \frac{\mu_k^*}{\pi} \right)^{1/2} \left( \frac{b_k^*}{2\pi} \right) + \left( \frac{\mu_k^*}{2\pi b_k^*} \right) - \frac{1}{4} \geq \frac{1}{4} N_0(\mu_k^*; b_k^*) + \frac{b_k^* (\mu_k^*)^{1/2}}{2\pi} + \frac{(\mu_k^*)^{1/2}}{2\pi b_k^*} - \frac{5}{4}. \quad (2.20)
\]

By (2.18) we have that the \(b_k^*\) are bounded uniformly in \(k\). It is known by [19] that there exist constants \(C < \infty\) and, for any \(\epsilon > 0\), \(\frac{1}{2} < \theta < \frac{141}{208} + \epsilon\) such that

\[
\frac{\mu}{\pi} + C\mu^{\theta/2} + 1 \geq N_0(\mu; b) \geq \frac{\mu}{\pi} - C\mu^{\theta/2}. \quad (2.21)
\]

So by (2.20) and (2.21) we conclude that

\[
b_k^* + 1 \geq \frac{4\pi k - \mu_k^*}{2(\mu_k^*)^{1/2}} + \frac{\pi C}{2} (\mu_k^*)^{(\theta - 1)/2} + \frac{2\pi \Theta_k}{(\mu_k^*)^{1/2}} + \frac{1}{2},
\]

where we have used that \(\mu_k^* \geq \mu^* = \pi^2\). We observe that \(\mu \mapsto \frac{4\pi k - \mu}{2\pi \mu^{1/2}} + \frac{\pi C}{2}\mu^{(\theta - 1)/2} + \frac{2\pi \Theta}{\mu^{1/2}}\) is decreasing.

By the optimality of \(\mu_k^*\) we have that

\[
b_k^* + 1 \geq \frac{4\pi k - \nu_k}{2\nu_k^{1/2}} + \frac{\pi C}{2\nu_k^{(1 - \theta)/2}} + \frac{2\pi \Theta_k}{\nu_k^{1/2}} + \frac{1}{2}.
\]

By (2.19) and (2.21) we have that

\[
k \leq N(\nu_k; 1) \leq \frac{\nu_k}{4\pi} + \frac{\nu_k^{1/2}}{\pi} + \frac{C\nu_k^{\theta/2}}{4}. \quad (2.22)
\]

It follows that

\[
b_k^* + 1 \leq \frac{4\pi k - \nu_k}{2\nu_k^{1/2}} + O(k^{(\theta - 1)/2}),
\]

and

\[
b_k^* = 1 + O(k^{(\theta - 1)/4}).
\]

This completes the proof of Theorem 1.1(ii).

**Proof of Theorem 1.1(iii).** First we obtain a lower bound for \(\mu_k^*\). By its maximality we have that \(\mu_k^* \geq \nu_k\), and so it suffices to obtain a lower bound for the latter. By (2.22) we have that

\[
k \leq \nu_k \left( \frac{4k}{\pi} \right)^{1/2} + O(k^{\theta/2}),
\]

where we have used Pólya’s Inequality \(\nu_k \leq 4\pi k\). This proves the lower bound in (1.5) since \((1 + \theta)/4 > \theta/2\).

To prove the upper bound we have by (2.20), (2.21) and (1.4) that

\[
N(\mu_k^*; b_k^*) \geq \frac{\mu_k^*}{4\pi} + \frac{b_k^* (\mu_k^*)^{1/2}}{2\pi} + \frac{\mu_k^*}{2\pi b_k^*} - \frac{C}{4} (\mu_k^*)^{\theta/2} - \frac{5}{4} \geq \frac{\mu_k^*}{4\pi} + \frac{\nu_k^{1/2}}{2\pi} + \frac{\nu_k^{1/2}}{b_k^*} - \frac{C}{4} (4\pi k)^{\theta/2} - \frac{5}{4} = \frac{\mu_k^*}{4\pi} + \frac{\nu_k^{1/2}}{\pi} + \nu_k^{1/2} O(k^{(\theta - 1)/4}) + O(k^{\theta/2}),
\]

\[
9
\]
where we have used the optimality of $\mu_k^*$ and Pólya’s inequality: $\nu_k \leq \mu_k^* \leq 4\pi k$. By Lemma 2.1 and Pólya’s inequality we have that $\nu_k^{1/2} = (4\pi k)^{1/2} + O(1)$. This shows that, since $\theta < 1$,

$$N(\mu_k^*; b_k^*) \geq \frac{\mu_k^*}{4\pi} + \left(\frac{4k}{\pi}\right)^{1/2} + O(k^{(\theta + 1)/4}).$$ (2.23)

We note that the multiplicity $\Theta_k$ of $\mu_k^*$ is equal to the number of lattice points in the first quadrant lying on the curve

$$\frac{\pi^2 x^2}{(b_k^*)^2} + \pi^2 (b_k^*)^2 y^2 = \mu_k^*.$$ (2.24)

The latter multiplicity is bounded by Theorem 1 in [20], and is of order $O(\ell^{2/3})$, where $\ell$ is the length of the curve defined in (2.24), which in turn equals $O((\mu_k^*)^{1/2}) = O(k^{1/2})$. So the multiplicity of $\mu_k^*$ is bounded by $O(k^{1/3})$. It follows by (2.23) that

$$O(k^{1/3}) + k \geq \frac{\mu_k^*}{4\pi} + \left(\frac{4k}{\pi}\right)^{1/2} + O(k^{(\theta + 1)/4}).$$

This completes the proof of Theorem 1.1(iii) since $\frac{1}{2} < (1 + \theta)/4$.

3 Neumann eigenvalues with a perimeter constraint

In general, the problems of maximising or minimising $\mu_k$ under a perimeter constraint are ill-posed. In fact, it is not difficult to see that for every $c > 0$

$$\inf \{ \mu_k(\Omega) : \Omega \text{ open, bounded with } \text{Per}(\Omega) = c \} = 0,$$ (3.1)

$$\sup \{ \mu_k(\Omega) : \Omega \text{ open, bounded with } \text{Per}(\Omega) = c \} = +\infty.$$ (3.2)

Indeed, the $k$-th eigenvalue of a set $\Omega$ which is the disjoint union of $k+1$ balls is equal to 0, so that the infimum under (3.1) is attained trivially. One can also construct a minimising sequence of connected sets where the $k$-th eigenvalue tends to zero. For example by connecting $k+1$ fixed disjoint balls with $k$ tubes of vanishing width (see [4]), while controlling the overall perimeter by rescaling.

For the maximisation problem, we construct the following example in $\mathbb{R}^2$. Let $\Lambda > 0$ be arbitrary, and let $l > 0$ be such that $l < \frac{\epsilon}{4}$, and $\frac{\pi^2}{32} \geq \Lambda$. Let $\Omega$ be the square with vertices $(0,0), (l,0), (l,-l), (0,-l)$. Then $\mu_1(\Omega) = \frac{\pi^2}{l^2}$. Consider the function $\phi : \mathbb{R} \to \mathbb{R}$ defined by $\phi(x) = C \sin(\frac{\pi x}{l})$, where $C$ is such that $\int_0^l \sqrt{1 + (\phi'(x))^2} dx = c-3l$. We replace the edge between the first two vertices by the graph of the function $\frac{1}{n}\phi(nx)$. In this way we construct a set $\Omega_{n,l}$ with $\text{Per}(\Omega_{n,l}) = c$. The sets $\Omega_{n,l}$ satisfy a uniform cone condition so that $\mu_1(\Omega_{n,l}) \to \mu_1(\Omega) = \frac{\pi^2}{l^2}$ as $n \to +\infty$. Hence for all $n$ sufficiently large $\mu_1(\Omega_{n,l}) \geq \frac{\pi^2}{32} \geq \frac{1}{2}$. Since $\Lambda > 0$ was arbitrary the supremum under (3.2) is $+\infty$. The above example is easily extended to dimensions larger than 2. We refer to [5] for related constructions.

Below we obtain some results for the variational problems (1.7), (1.8) with a perimeter constraint. We let $R_{a,b}$ denote a rectangle in $\mathbb{R}^2$ of side-lengths $a, b > 0$ so that $\text{Per}(R_{a,b}) = 2(a+b)$.

3.1 Analysis of the maximisation problem (1.7).

Our main theorem is the following.

**Theorem 3.1** For $k \in \mathbb{N}$, there is a unique maximising rectangle $R_{a_k^*,b_k^*}$ with $a_k^* = \frac{2}{k+1} \in (0,1]$ and $b_k^* = 2 - a_k^*$ such that

$$\mu_k(R_{a_k^*,b_k^*}) = \frac{\pi^2 k^2}{(2-a_k^*)^2} = \frac{\pi^2}{(a_k^*)^2} = \frac{\pi^2(k+1)^2}{4},$$

i.e. $\mu_k^* = \mu_k(R_{a_k^*,b_k^*})$ is realised by the modes $(k,0)$ and $(0,1)$.
Proof. We first show that for every $k \geq 0$, problem (1.7) has a solution.

Fix $k \in \mathbb{Z}^+$ and let $(R_{a_n,2-a_n})_n$, $a_n \in (0,1]$, be a maximising sequence of rectangles for $\mu_k$. By taking a subsequence if necessary we may assume that $(a_n)_n$ is monotone. Let $a_k^* = \lim_{n \to \infty} a_n$. Now, we claim that

$$a_k^* \geq \frac{2}{k+1}. \quad (3.3)$$

Suppose to the contrary that $a_k^* < \frac{2}{k+1}$. Then we have that

$$\frac{\pi^2 k^2}{(2-a_k^*)^2} < \frac{\pi^2}{(a_k^*)^2},$$

where the right-hand side above is $+\infty$ in the case that $a_k^* = 0$. Hence, the $k$ eigenvalues which are given by the pairs $(1,0), (2,0), \ldots, (k,0)$ are smaller than the eigenvalue which is given by the pair $(0,1)$. So $\mu_k^* = \frac{\pi^2 k^2}{(2-a_k^*)^2}$. However, if we consider $\hat{a}_k \in (a_k^*, \frac{2}{k+1})$, then

$$\mu_k(\hat{a}_k) = \frac{\pi^2 k^2}{(2-\hat{a}_k)^2} > \frac{\pi^2 k^2}{(2-a_k^*)^2},$$

which contradicts the maximality of $\mu_k^*$. This proves (3.3).

For $a_k = \frac{2}{k+1}$, we have that

$$\mu_k(R_{a_k,2-a_k}) = \frac{\pi^2 k^2}{(2-\frac{2}{k+1})^2} = \frac{\pi^2 (k+1)^2}{4}.$$ 

So, by maximality, we deduce that

$$\mu_k(R_{a_k^*,2-a_k^*}) \geq \frac{\pi^2 (k+1)^2}{4}. \quad (3.4)$$

Let

$$\mu_k(R_{a_k^*,2-a_k^*}) = \frac{\pi^2 p^2}{(2-a_k^*)^2} + \frac{\pi^2 q^2}{(a_k^*)^2},$$

for some $(p, q) \in (\mathbb{Z}^+)^2$, $p + q \leq k$.

Below we show that $q \leq 2$. Suppose to the contrary that $q \geq 3$. Then, by Pólya’s Inequality and since $a_k^* \in (0,1]$, we have that

$$\frac{9\pi^2}{(a_k^*)^2} \leq \mu_k(R_{a_k^*,2-a_k^*}) \leq \frac{4\pi k}{a_k^*(2-a_k^*)} \leq \frac{4\pi k}{a_k^*},$$

which implies that

$$a_k^* \geq \frac{9\pi}{4k}.$$ 

Hence, we have that

$$\mu_k^* \leq \frac{4\pi k}{a_k^*} \leq \frac{16 k^2}{9} < \frac{\pi^2 (k+1)^2}{4}.$$ 

This contradicts (3.4). So, for all $k \in \mathbb{Z}^+$, $\mu_k^*$ has $q \leq 2$.

Now we consider the case where $q = 2$, and note that

$$\frac{4\pi^2}{(a_k^*)^2} > \frac{\pi^2}{(2-a_k^*)^2} + \frac{\pi^2}{(a_k^*)^2},$$

since $a_k^* \in (0,1]$. This shows that the eigenvalues given by the pairs $(0,1)$ and $(1,1)$ are strictly smaller than the one given by the pair $(0,2)$. Below we will show that the eigenvalues given by the pairs
(0, 0), (1, 0), \ldots, (k - 2, 0) are also strictly smaller than the eigenvalue given by the pair (0, 2). By (3.4) and Pólya’s Inequality, we have that

\[ \frac{\pi^2(k + 1)^2}{4} \leq \mu_k(R_{a_k^*, 2 - a_k^*}) \leq \frac{4\pi k}{a_k^*(2 - a_k^*)}, \]

which implies that

\[ a_k^*(2 - a_k^*) \leq \frac{16}{\pi(k + 1)} \] (3.5)

Since \( a_k^*(2 - a_k^*) \leq 1 \), we see that (3.5) does not give any information about \( a_k^* \) for \( k = 1, 2, 3, 4 \). We first consider the case \( k \geq 5 \). By solving (3.5), and taking into account that \( a_k^* \leq 1 \), we have that

\[ a_k^* \leq 1 - \sqrt{1 - (16/\pi(k + 1))}. \] (3.6)

We wish to show that

\[ \frac{4\pi^2}{(a_k^*)^2} > \frac{\pi^2(k - 2)^2}{(2 - a_k^*)^2}. \] (3.7)

This is equivalent to showing that \( a_k^* < \frac{4}{k} \). The latter is clearly satisfied if \( 1 - \sqrt{1 - (16/\pi(k + 1))} \) < \( \frac{4}{k} \).

After elementary arithmetic, we see that this is equivalent to

\[ k > \frac{\pi}{\pi - 2} + \frac{2\pi}{(\pi - 2)k}. \] (3.8)

Since \( k \geq 5 \), we have that the right-hand side of (3.8) is bounded from above by \( \frac{2\pi}{(\pi - 2)k} \) < 5. So (3.7) holds for \( k \geq 5 \). So the eigenvalues which are given by the pairs \((0, 0), (1, 0), \ldots, (k - 2, 0), (0, 1), (1, 1)\) are all strictly smaller than the one which is given by the pair \((0, 2)\), and there are \( k + 1 \) of them. Hence \( \mu_k^* \) cannot have \( q = 0 \) or \( q = 1 \).

Either \( q = 0 \) and \( p = k \), \( \mu_k^* = \frac{\pi^2 k^2}{(2 - a_k^*)^2} \) and the first \( k + 1 \) eigenvalues are given by the pairs \((0, 0), (1, 0), \ldots, (k, 0)\). In this case, \( \mu_k^* \) cannot be simple. Otherwise the derivative of the mapping \( a \mapsto \mu_k(R_{a, 2 - a}) \) with respect to \( a \) would be non-vanishing as before, thus contradicting the maximality of \( \mu_k^* \). Hence \( \mu_k^* = \frac{\pi^2}{(a_k^*)^2} \), i.e. \( \mu_k^* \) is realised by the modes \((k, 0)\) and \((0, 1)\).

Or one of the first \( k + 1 \) eigenvalues is given by a pair \((p, 1), p \in \mathbb{Z}^+ \). Let \( \bar{p} \) be the smallest number such that

\[ \frac{\pi^2 p^2}{(2 - a_k^*)^2} + \frac{\pi^2}{(a_k^*)^2} > \mu_k^*. \]

Then all eigenvalues given by the pairs \((0, 1), (1, 1), \ldots, (\bar{p} - 1, 1)\) are in the list

\[ \mu_0(R_{a_k^*, 2 - a_k^*}), \mu_1(R_{a_k^*, 2 - a_k^*}), \ldots, \mu_k(R_{a_k^*, 2 - a_k^*}). \]

By considering the eigenvalues given by the pairs \((0, 0), (1, 0), \ldots, (k - \bar{p} + 1, 0)\), we deduce that

\[ \frac{\pi^2(k - \bar{p} + 1)^2}{(2 - a_k^*)^2} \geq \mu_k^* \geq \frac{\pi^2(k + 1)^2}{4}. \]

Thus we have that

\[ \bar{p} \leq \frac{1}{2}(k + 1)a_k^*, \]

which, together with (3.6), gives that

\[ \bar{p} \leq \frac{1}{2}(k + 1)(1 - \sqrt{1 - (16/\pi(k + 1))}) \]

\[ = \frac{8}{\pi} \left(1 + \left(1 - \frac{16}{\pi(k + 1)}\right)^{1/2}\right)^{-1}. \] (3.9)
The right-hand side of (3.9) is decreasing in \( k \). So for \( k \geq 5 \) have that the right-hand side of (3.9) is bounded from above by \( \frac{8}{3} \left( 1 + \left( 1 - \frac{3}{2\pi} \right)^{1/2} \right)^{-1} < 2 \). Hence \( p = 1 \), since \( \bar{p} \in \mathbb{N} \). Therefore \( p = 0 \).

So \( p = 0 \) and the first \( k + 2 \) eigenvalues are given by the pairs \((0,0),(1,0),\ldots,(k,0),(0,1)\). Then, as before, \( \mu_k^* = \frac{\pi^2 k^2}{(2-a_1 k^2)^2} = \frac{\pi^2}{(2-a_1)^2} \), since in either case \( \mu_k^* \) cannot be simple, i.e. \( \mu_k^* \) is realised by the modes \((k,0)\) and \((0,1)\).

It remains to deal with the cases \( k = 1, 2, 3, 4 \).

Let \( a_1 \in (0,1] \). Then

\[
\mu_1(R_{a_1,2-a_1}) = \frac{\pi^2 p^2}{(2-a_1)^2} + \frac{\pi^2 q^2}{a_1^2}
\]

for either the pair \((1,0)\) or the pair \((0,1)\). Since \( a_1 \in (0,1] \), \( \mu_1(R_{a_1,2-a_1}) = \frac{\pi^2}{(2-a_1)^2} \). This is maximal for \( a_1 = 1 \). Hence \( \mu_1^* = \pi^2 \) with \( a_1^* = 1 \) and corresponding modes \((1,0),(0,1)\).

Let \( a_2 \in (0,1] \). Then

\[
\mu_2(R_{a_2,2-a_2}) = \frac{\pi^2 p^2}{(2-a_2)^2} + \frac{\pi^2 q^2}{a_2^2},
\]

with \( p \leq 2, q \leq 2 \) and \( p + q \leq 2 \). The possible pairs which give \( \mu_2(R_{a_2,2-a_2}) \) are

\[
(2,0), (1,0), (1,1), (0,1), (0,2).
\]

Now \( \mu_1(R_{a_1,2-a_1}) = \frac{\pi^2}{(2-a_1)^2} \) is given by the pair \((1,0)\). So \( \mu_2(R_{a_2,2-a_2}) \) must be given by either \((2,0)\) or \((0,1)\). We have that

\[
\frac{4\pi^2}{(2-a_2)^2} \leq \frac{\pi^2}{a_2^2} \iff a_2 \leq \frac{2}{3},
\]

hence

\[
\mu_2(R_{a_2,2-a_2}) = \begin{cases} \frac{4\pi^2}{(2-a_2)^2}, & 0 < a_2 \leq \frac{2}{3} \\ \frac{\pi^2}{a_2^2}, & \frac{2}{3} < a_2 \leq 1. \end{cases}
\]

Thus we obtain that \( \mu_2^* = \frac{9\pi^2}{4} \) with \( a_2^* = \frac{2}{3} \) and corresponding modes \((2,0),(0,1)\).

Let \( a_3 \in (0,1] \). Then

\[
\mu_3(R_{a_3,2-a_3}) = \frac{\pi^2 p^2}{(2-a_3)^2} + \frac{\pi^2 q^2}{a_3^2},
\]

with \( p \leq 3, q \leq 2 \) and \( p + q \leq 3 \). The possible pairs which give \( \mu_3(R_{a_3,2-a_3}) \) are

\[(3,0), (2,0), (1,0), (2,1), (1,1), (0,1), (1,2), (0,2).\]

For \( 0 < a_2 \leq \frac{2}{3}, \mu_2(R_{a_2,2-a_2}) = \frac{4\pi^2}{(2-a_2)^2} \) is given by the pair \((2,0)\). So for \( 0 < a_3 \leq \frac{2}{3}, \mu_3(R_{a_3,2-a_3}) \) must be given by either \((3,0)\) or \((0,1)\). We have that

\[
\frac{9\pi^2}{(2-a_3)^2} \leq \frac{\pi^2}{a_3^2} \iff a_3 \leq \frac{1}{2},
\]

In addition, for \( \frac{2}{3} \leq a_2 \leq 1, \mu_2(R_{a_2,2-a_2}) = \frac{\pi^2}{a_2^2} \) is given by the pair \((0,1)\). So for \( \frac{2}{3} \leq a_3 \leq 1, \mu_3(R_{a_3,2-a_3}) \) must be given by either \((2,0)\) or \((1,1)\). We have that

\[
\frac{4\pi^2}{(2-a_3)^2} \leq \frac{\pi^2}{(2-a_3)^2} + \frac{\pi^2}{a_3^2} \iff a_3 \leq \sqrt{3} - 1,
\]

Thus, we obtain that

\[
\mu_3(R_{a_3,2-a_3}) = \begin{cases} \frac{9\pi^2}{(2-a_3)^2}, & 0 < a_3 \leq \frac{1}{2} \\ \frac{\pi^2}{a_3^2}, & \frac{1}{2} \leq a_3 \leq \frac{2}{3} \\ \frac{\pi^2}{a_3^2}, & \frac{2}{3} \leq a_3 \leq \sqrt{3} - 1 \\ \frac{\pi^2}{a_3^2} + \frac{\pi^2}{a_3^2}, & \sqrt{3} - 1 \leq a_3 \leq 1. \end{cases}
\]
We deduce that $\mu_4^1 = 4\pi^2$ with $a_5^* = \frac{1}{2}$ and corresponding modes $(3,0), (0,1)$.

Let $a_4 \in (0,1]$. Then
\[
\mu_4(R_{a_4,2-a_4}) = \frac{\pi^2 p^2}{(2-a_4)^2} + \frac{\pi^2 q^2}{a_4^2},
\]
with $p \leq 4, q \leq 2$ and $p + q \leq 4$. The possible pairs which give $\mu_4(R_{a_4,2-a_4})$ are
\[
(4,0), (3,0), (2,0), (1,0), (1,1), (2,1), (0,1), (2,2), (1,2), (0,2).
\]

For $0 < a_3 \leq \frac{1}{2}$, $\mu_3(R_{a_3,2-a_3}) = \frac{9\pi^2}{(2-a_3)^2}$ is given by the pair $(3,0)$. So for $0 < a_4 \leq \frac{1}{2}$, $\mu_4(R_{a_4,2-a_4})$ must be given by either $(4,0)$ or $(0,1)$. We have that
\[
\frac{16\pi^2}{(2-a_4)^2} \leq \frac{\pi^2}{a_4^2} \iff a_4 \leq \frac{2}{5}.
\]

In addition, for $\frac{1}{2} \leq a_2, a_3 \leq \frac{2}{7}$, $\mu_3(R_{a_3,2-a_3}) = \frac{\pi^2}{a_3^2}$ is given by the pair $(0,1)$, and $\mu_2(R_{a_2,2-a_2}) = \frac{4\pi^2}{(2-a_2)^2}$ is given by the pair $(2,0)$. So for $\frac{1}{2} \leq a_4 \leq \frac{2}{3}$, $\mu_4(R_{a_4,2-a_4})$ must be given by either $(3,0), (1,1)$ or $(0,2)$. We have that
\[
\frac{9\pi^2}{(2-a_4)^2} \leq \frac{\pi^2}{a_4^2} + \frac{\pi^2}{a_4^2} \iff a_4 \leq \frac{2}{7}(\sqrt{8} - 1),
\]
\[
\frac{9\pi^2}{(2-a_4)^2} \leq \frac{4\pi^2}{a_4^2} \iff a_4 \leq \frac{4}{5},
\]
\[
\frac{9\pi^2}{(2-a_4)^2} \leq \frac{4\pi^2}{a_4^2} \iff a_4 \in (0,1].
\]

For $\frac{2}{3} \leq a_3 \leq \sqrt{3} - 1$, $\mu_3(R_{a_3,2-a_3}) = \frac{4\pi^2}{(2-a_3)^2}$ is given by the pair $(2,0)$. Similarly to the above, for $\frac{2}{3} \leq a_4 \leq \sqrt{3} - 1$, $\mu_4(R_{a_4,2-a_4})$ must be given by either $(3,0)$ or $(1,1)$.

Finally, for $\sqrt{3} - 1 \leq a_3 \leq 1$, $\mu_3(R_{a_3,2-a_3}) = \frac{\pi^2}{(2-a_3)^2} + \frac{\pi^2}{a_3^2}$ is given by the pair $(1,1)$. So for $\sqrt{3} - 1 \leq a_4 \leq 1$, $\mu_4(R_{a_4,2-a_4})$ must be given by $(2,0)$, as $(1,0), (0,1), (1,1)$ have already been used for this range of $a$ by $\mu_1, \mu_2, \mu_3$ respectively.

Hence, we obtain that
\[
\mu_4(R_{a_4,2-a_4}) = \begin{cases} 
\frac{16\pi^2}{(2-a_4)^2}, & 0 < a_4 \leq \frac{2}{5}, \\
\frac{\pi^2}{a_4^2}, & \frac{2}{5} \leq a_4 \leq \frac{1}{2}, \\
\frac{9\pi^2}{(2-a_4)^2}, & \frac{1}{2} \leq a_4 \leq \frac{2}{7}(\sqrt{8} - 1), \\
\frac{\pi^2}{a_4^2} + \frac{\pi^2}{a_4^2}, & \frac{2}{7}(\sqrt{8} - 1) \leq a_4 \leq \sqrt{3} - 1, \\
\frac{4\pi^2}{(2-a_4)^2}, & \sqrt{3} - 1 \leq a_4 \leq 1.
\end{cases}
\]

Thus $\mu_4^* = \frac{25\pi^2}{4}$ with $a_5^* = \frac{2}{5}$ and corresponding modes $(4,0), (0,1)$.

**3.2 Analysis of the minimisation problem (1.8).**

Our main result is the following.

**Theorem 3.2** (i) If $k = 1$ then variational problem (1.8) does not have a minimiser, and the infimum equals $\frac{\pi^2}{4}$.

(ii) If $k \geq 2$ then variational problem (1.8) does have a minimiser.
(iii) If \( k \geq 2 \) and \( R_{a_k^*, b_k^*}, a_k^* \in (0, 1), b_k^* = 2 - a_k^* \) are minimisers then
\[
\lim_{k \to \infty} a_k^* = 1,
\]
i.e. any sequence of optimal rectangles for Problem (1.8) converges to the unit square, as \( k \to \infty \).

Proof. If \( k = 1 \) then \( (R_{\frac{\pi}{4} - \frac{\pi}{2}})_n \) is minimising and collapses to a segment of length 2. This proves the assertion under (i).

To prove (ii) we fix \( k \geq 2 \), and consider a minimising sequence for problem (1.8), \((R_{a_n, 2 - a_n})_n\) with \( a_n \in (0, 1] \). By taking a subsequence if necessary, \((a_n)_n\) converges and, without loss of generality, we may assume that it is a monotone sequence. Then \((a_n)_n\) cannot converge to 0. If \( a_n \to 0 \), then for \( n \) large enough such that \( 0 < a_n \leq \frac{2}{k+1} \), we have that
\[
\mu_k(R_{a_n, 2 - a_n}) = \frac{\pi^2 k^2}{(2 - a_n)^2} \to \frac{\pi^2 k^2}{4}.
\]
However, by minimality and by Pólya’s Inequality, we have that
\[
\mu_k(R_{a_n, 2 - a_n}) \leq \nu_k \leq 4\pi k.
\]
Clearly, this inequality leads to a contradiction as soon as \( \frac{\pi^2 k^2}{4} > 4\pi k \). That is the case for \( k \geq 6 \). So, for \( k \geq 6 \), \( a_n \to a_k^* > 0 \), which gives an optimal rectangle, \( R_{a_k^*, 2 - a_k^*} \).

Similarly to Section (3.1) we obtain the values of \( \mu_k^*(R_{a_k^*, 2 - a_k^*}) \) for \( k = 2, 3, 4, 5 \) by direct computation. In the table below, we list these values as well as the corresponding values of \( a_k^* \) and the minimising modes.

| \( k \) | \( \mu_k^* \) | \( a_k^* \) | minimising modes |
|---|---|---|---|
| 2 | \( \pi^2 \) | 1 | (1,0),(0,1) |
| 3 | \( \frac{2\pi^2}{3} \) | 1 | (1,1) |
| 4 | \( \frac{\pi^2 (2 + \sqrt{3})}{3} \) | \( \sqrt{3} - 1 \) | (2,0),(1,1) |
| 5 | \( 4\pi^2 \) | 1 | (2,0),(0,2) |

We note that a degenerating sequence of rectangles \( R_{a_2^{(n)}, 2 - a_2^{(n)}} \) with \( a_2^{(n)} \to 0 \), gives \( \mu_2(a_2^{(n)}) \to \pi^2 \).

In addition, we remark that \( \mu_5^* \) has only one minimising mode \((1, 1)\). By considering the derivative of the function \( \frac{\pi^2}{2a^2} + \frac{\pi^2}{\pi} \) with respect to \( a \), we see that the point \( a = 1 \) is a minimum point. This is due to the fact that for the mode \((1, 1)\) it is possible to obtain a vanishing derivative.

To prove assertion (iii) of the theorem we note that by minimality and Pólya’s Inequality,
\[
\mu_k(R_{a_k^*, 2 - a_k^*}) \leq \nu_k \leq 4\pi k.
\]
Recall that if \( R_{a_1, b_1}, R_{a_2, b_2} \) are two rectangles such that \( a_1 \leq a_2 \) and \( b_1 \leq b_2 \), then for every \( k \geq 0 \)
\( \mu_k(R_{a_1, b_1}) \geq \mu_k(R_{a_2, b_2}) \). The latter is a direct consequence of the expression of the eigenvalues on rectangles. Assume for some subsequence (still denoted with the same index \( k \)) that \( a_k^* \to \alpha \). Then, for every \( \delta > 0 \), there exists \( K_\delta \) such that for \( k \geq K_\delta \) we have that
\[
R_{a_k^*, 2 - a_k^*} \subset R_{\alpha + \delta, 2 - \alpha + \delta}.
\]
We have that
\[
\mu_k(R_{\alpha + \delta, 2 - \alpha + \delta}) \leq \mu_k(R_{a_k^*, 2 - a_k^*}) \leq \nu_k \leq 4\pi k.
\]
Using the Weyl asymptotic on \( R_{\alpha + \delta, 2 - \alpha + \delta} \), and letting \( k \to \infty \), we obtain
\[
\frac{4\pi}{(\alpha + \delta)(2 - \alpha + \delta)} \leq 4\pi.
\]
By subsequently letting $\delta \to 0$, we obtain that $\alpha(2-\alpha) \geq 1$, which leads to $\alpha = 1$. Hence, $\lim_{k \to \infty} a_k^* = 1$, and this limit is independent of the subsequence $(a_k^*)$.

It was shown in [3] that the corresponding sequence of minimisers for Dirichlet eigenvalues on rectangles with a perimeter constraint converges to the square with perimeter 4 as $k \to \infty$. A similar result holds in higher dimensions, and estimates for the rate of Hausdorff convergence were obtained ([3]).

3.3 Further remarks on higher dimensions.

We conclude with some remarks on the higher dimensional analogues of the problems that we investigated in this paper.

If $m \geq 3$ then problem (1.8) with fixed $k$ does not have a solution, since a sequence of cuboids with one very long edge has vanishing $k$-th eigenvalue.

In order to analyse problem (1.7), we first observe that for every $k \geq 1$ and every $m \geq 2$ the problem

$$\max \{ \mu_k(R) : R \text{ cuboid, } R \subseteq \mathbb{R}^m, |R| = 1 \},$$

has a solution. Indeed, if a maximising sequence is degenerating, then one of the edges of the cuboid is vanishing and so another one is blowing up. This second phenomenon produces vanishing eigenvalues, so it is excluded.

Now, concerning problem (1.7) in $\mathbb{R}^m$, $m \geq 3$, we claim that there exists a solution. Indeed, a maximising sequence of cuboids cannot have two (or more) vanishing edges, since this implies that another edge is blowing up, so the $k$-th eigenvalue is vanishing. There are only two possibilities: either there is convergence to a non-degenerate cuboid, or (only) one edge is vanishing. In the latter case, for a sufficiently short edge, the eigenvalues of the cuboid will be given by the eigenvalues of the $(m-1)$-dimensional complement cuboid which satisfies a volume constraint. That is, if $\left( R_{a_1^{(n)}, \ldots, a_m^{(n)}} \right)_n$ is a maximising sequence of cuboids such that for all $i \in \{1, \ldots, m\}$, $a_i^{(n)} \to a_i$ and, without loss of generality, $a_1^{(n)} \to 0$, then the perimeter constraint becomes $a_2 a_3 \ldots a_m = 4$. Thus, the eigenvalues of $R_{a_1, \ldots, a_m}$ are the eigenvalues of the $(m-1)$-dimensional cuboid with edges of length $a_2, a_3, \ldots, a_m$ subject to a volume constraint. At this point, making the vanishing edge longer would increase the eigenvalues.

For every $k$, let $R_k^*$ be a maximising cuboid. Then, for $k \to \infty$ the sequence $(R_k^*)_k$ has to collapse. By considering the Weyl asymptotic on $R_k^*$, $\mu_k^*$ would behave like $k^{\frac{2}{m-\tau}}$. However, if one chooses a particular sequence which collapses towards a fixed $(m-1)$-dimensional cuboid, then $\mu_k^*$ would behave like $k^{\frac{2}{m-1}}$.
