March 31, 2022

Abstract

Using a recent reformulation of the analysis of nuclear parity-violation (PV) using the framework of effective field theory (EFT), we show how predictions for parity-violating observables in low energy light hadronic systems can be understood in an analytic fashion. It is hoped that such an analytic approach may encourage additional experimental work as well as add to the understanding of such parity-violating phenomena, which is all too often obscured by its description in terms of numerical results obtained from complex two-body potential codes.
1 Introduction

I never had the pleasure of meeting Dubravko Tadić, which is a shame, since he and I worked on many parallel subjects over the years. An example of this is his recent work on hypernuclear decay[1] as well as his early papers on what is usually called nuclear parity violation[2]. It is the latter which I wish to focus on in this paper, which I dedicate to Dubravko’s memory.

The cornerstone of traditional nuclear physics is the study of nuclear forces and, over the years, phenomenological forms of the nuclear potential have become increasingly sophisticated. In the nucleon-nucleon (NN) system, where data abound, the present state of the art is indicated, for example, by phenomenological potentials such as AV18 that are able to fit phase shifts in the energy region from threshold to 350 MeV in terms of $\sim 40$ parameters. Progress has also been made in the description of few-nucleon systems[3]. At the same time, in recent years a new technique—effective field theory (EFT)—has been used in order to attack this problem using the symmetries of QCD[4]. In this approach the nuclear interaction is separated into long- and short-distance components. In its original formulation[5], designed for processes with typical momenta comparable to the pion mass, $Q \sim m_\pi$, the long-distance component is described fully quantum mechanically in terms of pion exchange, while the short-distance piece is described in terms of a small number of phenomenologically-determined contact couplings. The resulting potential[6,7] is approaching[8,9] the degree of accuracy of purely-phenomenological potentials. Even higher precision can be achieved at lower momenta, where all interactions can be taken as short-ranged, as has been demonstrated not only in the NN system[10,11], but also in the three-nucleon system[12,13]. Precise $\sim 1\%$ values have been generated also for low-energy, astrophysically-important cross sections for reactions such as $n + p \rightarrow d + \gamma$[14] and $p + p \rightarrow d + e^+ + \nu_e$[15]. However, besides providing reliable values for such quantities, the use of EFT techniques allows for the realistic estimation of the size of possible corrections.

Over the past nearly half century there has also developed a series of measurements attempting to illuminate the parity-violating (PV) nuclear interaction. Indeed the first experimental paper of which I am aware was that of Tanner in 1957[16], shortly after the experimental confirmation of parity violation in nuclear beta decay by Wu et al.[17]. Following seminal theoretical work by Michel in 1964[18] and that of other authors in the late 1960’s[19,20,21], the results of such experiments have generally been analyzed in terms of a meson-exchange picture, and in 1980 the work of Desplanques, Donoghue, and Holstein (DDH) developed a comprehensive and general meson-exchange framework for the analysis of such interactions in terms of seven parameters representing weak parity-violating meson-nucleon couplings[22]. The DDH interaction has become the standard setting by which hadronic and nuclear PV processes are now analyzed theoretically.

It is important to observe, however, that the DDH framework is, at heart, a model based on a meson-exchange picture. Provided one is interested primarily in near-threshold phenomena, use of a model is unnecessary, and one can
instead represent the PV nuclear interaction in a model-independent effective-field-theoretic fashion, as recently developed by Zhu et al.\[23\]. In this approach, the low energy PV NN interaction is entirely short-ranged, and the most general potential depends at leading order on 11 independent operators parameterized by a set of 11 *a priori* unknown low-energy constants (LEC’s). When applied to low-energy ($E_{cm} \leq 50$ MeV) two-nucleon PV observables, however, such as the neutron spin asymmetry in the capture reaction $\vec{n} + p \rightarrow d + \gamma$, the 11 operators reduce to a set of five independent PV amplitudes which may be determined by an appropriate set of measurements, as described in \[23\], and an experimental program which should result in the determination of these couplings is underway. This is an important goal, since such interactions are interesting not only in their own right but also as background effects entering atomic PV measurements\[24\] as well as experiments that use parity violation in electromagnetic interactions in order to probe nuclear structure\[25\].

Completion of such a low-energy program would serve at least three additional purposes:

i) First, it would provide particle theorists with a set of five benchmark numbers which are in principle explainable from first principles. This situation would be analogous to what one encounters in chiral perturbation theory for pseudoscalars, where the experimental determination of the ten LEC’s appearing in the $O(p^4)$ Lagrangian presents a challenge to hadron structure theory. While many of the $O(p^4)$ LEC’s are saturated by $t$-channel exchange of vector mesons, it is not clear *a priori* that the analogous PV NN constants are similarly saturated (as assumed implicitly in the DDH model).

ii) Moreover, analysis of the PV NN LEC’s involves the interplay of weak and strong interactions in the strangeness conserving sector. A similar situation occurs in $\Delta S = 1$ hadronic weak interactions, and the interplay of strong and weak interactions in this case are both subtle and only partially understood, e.g., by the well-known the $\Delta I = 1/2$ rule enigma. The additional information in the $\Delta S = 0$ sector provided by a well-defined set of experimental numbers would undoubtedly shed light on this fundamental problem.

iii) Finally, the information derived from the low-energy nuclear PV program would also provide a starting point for a reanalysis of PV effects in many-body systems. Until now, one has attempted to use PV observables obtained from both few- and many-body systems in order to determine the seven PV meson-nucleon couplings entering the DDH potential, and several inconsistencies have emerged. The most blatant is the vastly different value for $h_x$ obtained from the PV $\gamma$-decays of $^{18}$F, $^{19}$F and from the combination of the $\vec{p}\vec{p}$ asymmetry and the cesium anapole moment\[24\]. The origin of this clash could be due to any one of a number of factors. Using the operator constraints derived from the few-body program as input into
the nuclear analysis could help clarify the situation. It may be, for example, that the remaining combinations of operators not constrained by the few-body program play a more significant role in nuclei than implicitly assumed by the DDH framework. Alternatively, truncation of the model space in shell model treatments of the cesium anapole moment may be the culprit. In any case, approaching the nuclear problem from a more systematic perspective and drawing upon the results of few-body studies would undoubtedly represent an advance for the field.

The purpose of the present paper is not, however, to make the case for the effective field theory program—this has already been undertaken in [23]. Also, it is not our purpose to review the subject of hadronic parity violation—indeed there exist a number of comprehensive recent reviews of this subject [24,27,28]. However, although the basic ideas of the physics are clearly set out in these works, because the NN interaction is generally represented in terms of a somewhat forbidding two-body interaction, any calculations which are done involve state of the art potentials and are somewhat mysterious except to those priests who preach this art. Rather, in this paper, we wish to argue that this need not be the case. Below we eschew a high precision but complex nuclear wavefunction approach in favor of a simple analytic treatment which captures the flavor of the subject without the complications associated with a more rigorous calculation. We show that, provided that one is working in the low energy region, one can use a simple effective interaction approach to the PV NN interaction wherein the parity violating NN interaction is described in terms of just five real numbers, which characterize S-P wave mixing in the spin singlet and triplet channels, and the experimental and theoretical implications can be extracted within a basic effective interaction technique, wherein the nucleon interactions are represented by short range potentials. This is justified at low energy because the scales indicated by the scattering lengths—$a_s \sim -20$ fm, $a_t \sim 5$ fm—are both much larger than the $\sim 1$ fm range of the nucleon-nucleon strong interaction. Of course, precision analysis should still be done with the best and most powerful contemporary wavefunctions such as the Argonne V18 or Bonn potentials. Nevertheless, for a simple introduction to the field, we feel that the elementary discussion given below is didactically and motivationally useful. In the next section then we present a brief review of the standard DDH formalism, since this is the basis of most analysis, as well as the EFT picture in which we shall work. Then in the following section we show how the basic physics of the NN system can be elicited in a simple analytic fashion, focusing in particular on the deuteron. With this as a basis we proceed to the parity-violating NN interaction and develop a simple analytic description of low energy PV processes. We summarize our findings in a brief concluding section.

2 Hadronic Parity Violation: Old and New

The essential idea behind the conventional DDH framework relies on the fairly successful representation of the parity-conserving $NN$ interaction in terms of a
single meson-exchange approach. Of course, this technique requires the use of strong interaction couplings of the lightest vector and pseudoscalar mesons

\[
H_{st} = ig_{\pi NN}\bar{N}\gamma_5\tau \cdot \pi N + g_{\rho}\bar{N}\left(\gamma_\mu + i\frac{X_\rho}{2m_N}\sigma_{\mu\nu}k^\nu\right)\tau \cdot \rho^\mu N
+ g_{\omega}\bar{N}\left(\gamma_\mu + i\frac{X_\omega}{2m_N}\sigma_{\mu\nu}k^\nu\right)\omega^\mu N,
\]

whose values are reasonably well determined. The DDH approach to the parity-violating weak interaction utilizes a similar meson-exchange picture, but now with one strong and one weak vertex — cf. Fig. 1. We require then an effective parity-violating \textit{NNM} Hamiltonian in analogy to Eq. (1). The process is simplified somewhat by Barton’s theorem, which requires that, in the CP-conserving limit, which we employ, exchange of neutral pseudoscalars is forbidden [29]. From general arguments, the effective Hamiltonian for such interactions must take the form

\[
H_{wk} = \frac{i}{\sqrt{2}}\bar{N}(\tau \times \pi)_3\gamma_5 N + \bar{N}\left(h_{\pi}^{\prime} \tau \cdot \rho^\mu + h_{\rho}^{\prime} \tau_3\rho^\mu + \frac{h_{\rho}^2}{2\sqrt{6}}(3\tau_3\rho_3^\mu - \tau \cdot \rho^\mu)\right)\gamma_\mu\gamma_5 N
+ \bar{N}\left(h_{\omega}^{\prime} \omega_3 \gamma_5 N - h_{\rho}^{\prime} \bar{N}(\tau \times \rho^\mu)_3\sigma_{\mu\nu}k^\nu\right)\gamma_5 N.
\]

We see that there exist, in this model, seven unknown weak couplings $h_{\pi}$, $h_{\rho}^0$, ... However, quark model calculations suggest that $h_{\rho}^{\prime 1}$ is quite small [30], so this term is usually omitted, leaving parity-violating observables described in terms of just six constants. DDH attempted to evaluate such PV couplings using basic quark-model and symmetry techniques, but they encountered significant theoretical uncertainties. For this reason their results were presented in terms of an allowable range for each, accompanied by a “best value” representing their best guess for each coupling. These ranges and best values are listed in Table 2 together with predictions generated by subsequent groups [31, 32].

Before making contact with experimental results, however, it is necessary to convert the \textit{NNM} couplings generated above into an effective parity-violating \textit{NN} potential. Inserting the strong and weak couplings, defined above into the
Table 1: Weak NNM couplings as calculated in Refs. [22, 31, 32]. All numbers are quoted in units of the “sum rule” value \( g_\pi = 3.8 \cdot 10^{-8} \).

Meson-exchange diagrams shown in Fig. 1 and taking the Fourier transform, one finds the DDH effective parity-violating \( NN \) potential

\[
V_{DDH}^{PV}(\vec{r}) = i \frac{h_\pi g_\pi NN}{\sqrt{2}} \left( \frac{\tau_1 - \tau_2}{2} \right)_3 (\vec{\sigma}_1 + \vec{\sigma}_2) \cdot \left[ \frac{\vec{p}_1 - \vec{p}_2}{2m_N}, w_\pi(r) \right] \\
- g_\rho \left( h_\rho^0 r_1 \cdot r_2 + h_\rho^1 \left( \frac{\tau_1 + \tau_2}{2} \right)_3 + h_\rho^2 \frac{(3r_1^3 r_2^3 - r_1 \cdot r_2)}{2\sqrt{6}} \right) \\
\left( (\vec{\sigma}_1 - \vec{\sigma}_2) \cdot \left\{ \frac{\vec{p}_1 - \vec{p}_2}{2m_N}, w_\rho(r) \right\} + i(1 + \chi_V) \vec{\sigma}_1 \times \vec{\sigma}_2 \cdot \left[ \frac{\vec{p}_1 - \vec{p}_2}{2m_N}, w_\rho(r) \right] \right) \\
- g_\omega \left( h_\omega^0 + h_\omega^1 \left( \frac{\tau_1 + \tau_2}{2} \right)_3 \right) \\
\left( (\vec{\sigma}_1 - \vec{\sigma}_2) \cdot \left\{ \frac{\vec{p}_1 - \vec{p}_2}{2m_N}, w_\omega(r) \right\} + i(1 + \chi_S) \vec{\sigma}_1 \times \vec{\sigma}_2 \cdot \left[ \frac{\vec{p}_1 - \vec{p}_2}{2m_N}, w_\omega(r) \right] \right) \\
- (g_\omega h_\omega^1 - g_\rho h_\rho^1) \left( \frac{\tau_1 - \tau_2}{2} \right)_3 (\vec{\sigma}_1 + \vec{\sigma}_2) \cdot \left\{ \frac{\vec{p}_1 - \vec{p}_2}{2m_N}, w_\rho(r) \right\} \\
- g_\rho h_\rho^1 i \left( \frac{\tau_1 \times \tau_2}{2} \right)_3 (\vec{\sigma}_1 + \vec{\sigma}_2) \cdot \left[ \frac{\vec{p}_1 - \vec{p}_2}{2m_N}, w_\rho(r) \right],
\]

where \( w_i(r) = \exp(-m_i r)/(4\pi r) \) is the usual Yukawa form, \( r = |\vec{x}_1 - \vec{x}_2| \) is the separation between the two nucleons, and \( \vec{p}_i = -i \nabla_i \).

Nearly all experimental results involving nuclear parity violation have been analyzed using \( V_{DDH}^{PV} \) for the past twenty-some years. At present, however, there appear to exist discrepancies between the values extracted for the various DDH couplings from experiment. In particular, the values of \( h_\pi \) and \( h_\rho^0 \) extracted from \( pp \) scattering and the \( \gamma \) decay of \(^{18}\)F do not appear to agree with the corresponding values implied by the anapole moment of \(^{133}\)Cs measured in atomic parity violation [33].

These inconsistencies suggest that the DDH framework may not, after all, adequately characterize the PV NN interaction and provides motivation for our reformulation using EFT. In this approach, the effective PV potential is entirely
short-ranged and has the co-ordinate space form

\[ V_{\text{eff}}^{PV}(\vec{r}) = \frac{2}{\Lambda^4} \left\{ \left[ C_1 + C_2 \frac{\tau_1^z + \tau_2^z}{2} \right] (\sigma_1 - \sigma_2) \cdot \{-i\nabla, f_m(r)\} \right. \]

\[ + \left[ \tilde{C}_1 + \tilde{C}_2 \frac{\tau_1^z + \tau_2^z}{2} \right] i(\sigma_1 \times \sigma_2) \cdot [-i\nabla, f_m(r)] \]

\[ + \left[ C_2 - C_4 \right] \frac{\tau_1^z - \tau_2^z}{2} (\sigma_1 + \sigma_2) \cdot \{-i\nabla, f_m(r)\} \]

\[ + \left[ C_3 \tau_1 \cdot \tau_2 + C_4 \frac{\tau_1^z + \tau_2^z}{2} + I_{ab} C_5 \tau_{1a} \tau_{2b} \right] (\sigma_1 - \sigma_2) \cdot \{-i\nabla, f_m(r)\} \]

\[ + \left[ \tilde{C}_3 \tau_1 \cdot \tau_2 + \tilde{C}_4 \frac{\tau_1^z + \tau_2^z}{2} + I_{ab} \tilde{C}_5 \tau_{1a} \tau_{2b} \right] i(\sigma_1 \times \sigma_2) \cdot [-i\nabla, f_m(r)] \]

\[ + \left[ C_6i e^{ab} \tau_{1a} \tau_{2b} (\sigma_1 + \sigma_2) \cdot [-i\nabla, f_m(r)] \right] \] \(, (4)\)

where

\[ I^{ab} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}, \quad (5) \]

and \( f_m(r) \) is a function which

i) is strongly peaked, with width \( \sim 1/m \) about \( r = 0 \), and

ii) approaches \( \delta^{(3)}(\vec{r}) \) in the zero width—\( m \to \infty \)—limit.

A convenient form, for example, is the Yukawa-like function

\[ f_m(r) = \frac{m^2}{4\pi r} \exp(-mr) \quad (6) \]

where \( m \) is a mass chosen to reproduce the appropriate short range effects. Actually, for the purpose of carrying out actual calculations, one could just as easily use the momentum-space form of \( V_{\text{SR}}^{PV} \), thereby avoiding the use of \( f_m(r) \) altogether. Nevertheless, the form of Eq. 4 is useful when comparing with the DDH potential. For example, we observe that the same set of spin-space and isospin structures appear in both \( V_{\text{eff}}^{PV} \) and the vector-meson exchange terms in \( V_{\text{DDH}}^{PV} \), though the relationship between the various coefficients in \( V_{\text{eff}}^{PV} \) is more general. In particular, the DDH model is tantamount to assuming

\[ \frac{\tilde{C}_1}{C_1} = \frac{\tilde{C}_2}{C_2} = 1 + \chi_\omega, \quad (7) \]

\[ \frac{\tilde{C}_3}{C_3} = \frac{\tilde{C}_4}{C_4} = \frac{\tilde{C}_5}{C_5} = 1 + \chi_\rho, \quad (8) \]

and taking \( m \sim m_\rho, m_\omega \), assumptions which may not be physically realistic. Nevertheless, if this ansatz is made, the EFT and DDH results coincide provided the identifications
are made.

Before beginning our analysis of PV NN scattering, however, it is important to review the analogous PC NN scattering case, since it is more familiar and it is a useful arena wherein to compare conventional and effective field theoretic methods.

3 Parity Conserving NN Scattering

We begin our discussion with a brief review of conventional scattering theory. In the usual partial wave expansion, we can write the scattering amplitude as

\[ f(\theta) = \sum_\ell (2\ell + 1)a_\ell(k)P_\ell(\cos \theta) \quad (9) \]

where \(a_\ell(k)\) has the form

\[ a_\ell(k) = \frac{1}{k e^{i\delta_\ell(k)}} \sin \delta_\ell(k) = \frac{1}{k \cot \delta_\ell(k) - ik} \quad (10) \]

3.1 Conventional Analysis

Working in the usual potential model approach, a general expression for the scattering phase shift \(\delta_\ell(k)\) is

\[ \sin \delta_\ell(k) = -k \int_0^\infty dr' r' j_\ell(kr')2m_r V(r')u_{\ell,k}(r') \quad (11) \]

where \(m_r\) is the reduced mass and

\[ u_{\ell,k}(r) = r \cos \delta_\ell(k) j_\ell(kr) + kr \int_0^r dr' r' j_\ell(kr')n_\ell(kr)u_{\ell,k}(r')2m_r V(r') + kr \int_r^\infty dr' r' j_\ell(kr')n_\ell(kr')u_{\ell,k}(r')2m_r V(r') \quad (12) \]
is the scattering wavefunction. At low energies one can characterize the analytic function $k^{2\ell+1} \cot \delta(k)$ via an effective range expansion:

$$k^{2\ell+1} \cot \delta(k) = -\frac{1}{a} + \frac{1}{2} r_\ell k^2 + \ldots$$ \hspace{1cm} \text{(13)}$$

Then from Eq. (11) we can identify the scattering length as

$$a_\ell = \frac{1}{[(2\ell + 1)!!]^2} \int_0^\infty dr' (r')^{2\ell+2} 2 m_r V(r') + O(V^2)$$ \hspace{1cm} \text{(14)}$$

For simplicity, we consider only S-wave interactions. Then for neutron-proton interactions, for example, one finds

$$a_0^\delta = -23.715 \pm 0.015 \text{ fm}, \quad r_0^\delta = 2.73 \pm 0.03 \text{ fm}$$
$$a_0^t = 5.423 \pm 0.005 \text{ fm}, \quad r_0^t = 1.73 \pm 0.02 \text{ fm}$$ \hspace{1cm} \text{(15)}$$

for scattering in the spin-singlet and spin-triplet channels respectively. The existence of a bound state $E_B = -\gamma^2/2 m_r$ is indicated by the presence of a pole along the positive imaginary $k$-axis—i.e. $\gamma > 0$ under the analytic continuation $k \to i\gamma$—

$$\frac{1}{a_0} + \frac{1}{2} r_0 \gamma^2 - \gamma = 0$$ \hspace{1cm} \text{(16)}$$

We see from Eq. (15) that there is no bound state in the np spin-singlet channel, but in the spin-triplet system there exists a solution

$$\kappa = \frac{1}{r_0^t} - \frac{V_0}{a_0^t} = 45.7 \text{ MeV}, \quad \text{i.e. } E_B = -2.23 \text{ MeV}$$ \hspace{1cm} \text{(17)}$$

corresponding to the deuteron.

As a specific example, suppose we utilize a simple square well potential to describe the interaction

$$V(r) = \begin{cases} -V_0 & r \leq R \\ 0 & r > R \end{cases}$$ \hspace{1cm} \text{(18)}$$

For S-wave scattering the wavefunction in the interior and exterior regions can then be written as

$$\psi^{(+)}(r) = \begin{cases} N j_0(Kr) & r \leq R \\ N'(j_0(kr) \cos \delta_0 - n_0(kr) \sin \delta_0) & r > R \end{cases}$$ \hspace{1cm} \text{(19)}$$

where $j_0, n_0$ are spherical harmonics and the interior, exterior wavenumbers are given by $k = \sqrt{2m_r E}$, $K = \sqrt{2m_r (E + V_0)}$ respectively. The connection between the two forms can be made by matching logarithmic derivatives at the boundary, which yields

$$k \cot \delta \simeq \frac{1}{R} \left[ 1 + \frac{1}{KRF(KR)} \right] \quad \text{with} \quad F(x) = \cot x - \frac{1}{x}$$ \hspace{1cm} \text{(20)}$$
Making the effective range expansion—Eq \( \text{13} \)—we find an expression for the scattering length

\[
a_0 = R \left[ 1 - \tan(K_0 R) \right] \quad \text{where} \quad K_0 = \sqrt{2m_r V_0} \tag{21}
\]

Note that for weak potentials—\( K_0 R << 1 \)—this form agrees with the general result Eq. \( \text{13} \)—

\[
a_0 = \int_0^\infty dr' r'^2 2m_r V(r') = -\frac{2m_r}{3} R^3 V_0 + O(V_0^2) \tag{22}
\]

### 3.2 Coulomb Effects

When Coulomb interactions are included the analysis becomes somewhat more challenging. Suppose first that only same charge (e.g., proton-proton) scattering is considered and that, for simplicity, we describe the interaction in terms of a potential of the form

\[
V(r) = \begin{cases} 
U(r) & r < R \\
\alpha & r > R
\end{cases} \tag{23}
\]

\( i.e. \) a strong attraction—\( U(r) \)—at short distances, in order to mimic the strong interaction, and the repulsive Coulomb potential—\( \alpha/r \)—at large distance, where \( \alpha \simeq 1/137 \) is the fine structure constant. The analysis of the scattering then proceeds as above but with the replacement of the exterior spherical Bessel functions by corresponding Coulomb wavefunctions \( F_0^+, G_0^+ \)

\[
\begin{align*}
F_0^+(r) & \quad \frac{kr}{kr << 1} \quad C(\eta_+(k))(1 + \frac{r}{2a_B} + \ldots) \\
G_0^+(r) & \quad \frac{kr}{kr << 1} \quad -\frac{1}{C(\eta_+(k))} \left\{ \frac{1}{kr} \\
& \quad + \quad 2\eta_+(k) \left[ h(\eta_+(k)) + 2\gamma_E - 1 + \ln \frac{r}{a_B} \right] + \ldots \right\}
\end{align*} \tag{24}
\]

whose explicit form can be found in reference \[36\]. For our purposes we require only the form of these functions in the limit \( kr << 1 \)—

\[
\begin{align*}
F_0^+(r) & \quad \frac{kr}{kr << 1} \quad C(\eta_+(k))(1 + \frac{r}{2a_B} + \ldots) \\
G_0^+(r) & \quad \frac{kr}{kr << 1} \quad -\frac{1}{C(\eta_+(k))} \left\{ \frac{1}{kr} \\
& \quad + \quad 2\eta_+(k) \left[ h(\eta_+(k)) + 2\gamma_E - 1 + \ln \frac{r}{a_B} \right] + \ldots \right\}
\end{align*} \tag{25}
\]

Here \( \gamma_E = 0.577215 .. \) is the Euler constant,

\[
C^2(x) = \frac{2\pi x}{\exp(2\pi x) - 1} \tag{26}
\]

is the usual Coulombic enhancement factor, \( a_B = 1/m_r \alpha \) is the Bohr radius, \( \eta_+(k) = 1/2ka_B \), and

\[
h(\eta_+(k)) = \text{Re}H(i\eta_+(k)) = \eta_+^2(k) \sum_{n=1}^{\infty} \frac{1}{n(n^2 + \eta_+^2(k))} - \ln \eta_+(k) - \gamma_E \tag{27}
\]
where \( H(x) \) is the analytic function
\[
H(x) = \psi(x) + \frac{1}{2x} - \ln(x)
\]
Equating interior and exterior logarithmic derivatives we find
\[
KF(KR) = \frac{\cos \delta_0 F_0^+(R) - \sin \delta_0 G_0^+(R)}{\cos \delta_0 F_0^0(R) - \sin \delta_0 G_0^0(R)}
\]
\[
= \frac{k \cot \delta_0 C^2(\eta_+(k)) \frac{1}{a_B} - \frac{1}{R}}{k \cot \delta_0 C^2(\eta_+(k)) + \frac{1}{a_B} \left[ h(\eta_+(k)) - \ln \frac{a_B}{R} + 2\gamma_E - 1 \right]}
\]
Since \( R \ll a_B \) Eq. 29 can be written in the form
\[
k \cot \delta_0 C^2(\eta_+(k)) + \frac{1}{a_B} \left[ h(\eta_+(k)) - \ln \frac{a_B}{R} + 2\gamma_E - 1 \right] \approx -\frac{1}{a_0}
\]
The scattering length \( a_C \) in the presence of the Coulomb interaction is conventionally defined as[37]
\[
k \cot \delta_0 C^2(\eta_+(k)) + \frac{1}{a_B} h(\eta_+(k)) = -\frac{1}{a_C} + \ldots
\]
so that we have the relation
\[
-\frac{1}{a_0} = -\frac{1}{a_C} - \frac{1}{a_B} (\ln \frac{a_B}{R} + 1 - 2\gamma_E)
\]
between the experimental scattering length—\( a_C \)—and that which would exist in the absence of the Coulomb interaction—\( a_0 \).

As an aside we note that, strictly speaking, \( a_0 \) is not itself an observable since the Coulomb interaction cannot be turned off. However, in the case of the pp interaction isospin invariance requires \( a_0^{pp} = a_0^{nn} \) so that one has the prediction
\[
-\frac{1}{a_0^{nn}} = -\frac{1}{a_0^{pp}} - \alpha M_N (\ln \frac{1}{\alpha M_N R} + 1 - 2\gamma_E)
\]
While this is a model dependent result, Jackson and Blatt have shown, by treating the interior Coulomb interaction perturbatively, that a version of this result with \( 1 - 2\gamma_E \rightarrow 0.824 - 2\gamma_E \) is approximately valid for a wide range of strong interaction potentials[36] and the correction indicated in Eq. 33 is essential in restoring agreement between the widely discrepant—\( a_0^{nn} = -18.8 \) fm vs. \( a_0^{pp} = -7.82 \) fm—values obtained experimentally.

Returning to the problem at hand, the experimental scattering amplitude can then be written as
\[
f_C^+(k) = \frac{e^{2\sigma_0} C^2(\eta_+(k))}{-\frac{1}{a_C} - \frac{1}{a_B} h(\eta_+(k)) - ikC^2(\eta_+(k))}
\]
\[
= \frac{e^{2\sigma_0} C^2(\eta_+(k))}{-\frac{1}{a_C} - \frac{1}{a_B} H(\eta_+(k))}
\]
where \( \sigma_0 = \arg \Gamma(1 - i \eta_+(k)) \) is the Coulomb phase.
3.3 Effective Field Theory Analysis

Identical results may be obtained using effective field theory (EFT) methods and in many ways the derivation is clearer and more intuitive.[38] The basic idea here is that since we are only interested in interactions at very low energy, a scattering length description is quite adequate. From Eq. 22 we see that, at least for weak potentials, the scattering length has a natural representation in terms of the momentum space potential \( \tilde{V}(\vec{p} = 0) \) —

\[
a_0 = \frac{m_r}{2\pi} \int d^3r V(r) = \frac{m_r}{2\pi} \tilde{V}(\vec{p} = 0) \tag{35}
\]

and it is thus natural to perform our analysis using a simple contact interaction. First consider the situation that we have two particles A,B interacting only via a local strong interaction, so that the effective Lagrangian can be written as

\[
\mathcal{L} = \sum_{i=A}^{B} \bar{\Psi}_i (i\frac{\partial}{\partial t} + \frac{\nabla^2}{2m_i}) \Psi_i - C_0 \bar{\Psi}_A \Psi_A \bar{\Psi}_B \Psi_B + \ldots \tag{36}
\]

The T-matrix is then given in terms of the multiple scattering series shown in Figure 1

\[
T_{fi}(k) = -\frac{2\pi}{m_r} f(k) = C_0 + C_0^2 G_0(k) + C_0^3 G_0^2(k) + \ldots = \frac{C_0}{1 - C_0 G_0(k)} \tag{37}
\]

where \( G_0(k) \) is the amplitude for particles A, B to travel from zero separation to zero separation—i.e the propagator \( D_F(k; \vec{r}' = 0, \vec{r} = 0) \) —

\[
G_0(k) = \lim_{\vec{r}', \vec{r} \to 0} \int \frac{d^3s}{(2\pi)^3} \frac{1}{2m_r} \frac{i \vec{r}' \cdot \vec{s}}{2m_r} + i\epsilon = \int \frac{d^3s}{(2\pi)^3} \frac{2m_r}{k^2 - s^2 + i\epsilon} \tag{38}
\]

Equivalently \( T_{fi}(k) \) satisfies a Lippman-Schwinger equation

\[
T_{fi}(k) = C_0 + C_0 G_0(k) T_{fi}(k). \tag{39}
\]

whose solution is given in Eq. [37]

![Figure 2: The multiple scattering series.](image)

The complication here is that the function \( G_0(k) \) is divergent and must be defined via some sort of regularization. There are a number of ways by which to do this, but perhaps the simplest is to use a cutoff regularization with \( k_{max} = \mu \).
which simply eliminates the high momentum components of the wavefunction completely. Then

$$G_0(k) = -\frac{m_r}{2\pi} \left( \frac{2\mu}{\pi} + ik \right)$$

(40)

(Other regularization schemes are similar. For example, one could subtract at an unphysical momentum point, as proposed by Gegelia\[39]\)

$$G_0(k) = \int \frac{d^3s}{(2\pi)^3} \left( \frac{2m_r}{k^2 - s^2 + i\epsilon} + \frac{2m_r}{\mu^2 + s^2} \right) = -\frac{m_r}{2\pi} (\mu + ik)$$

(41)

which has been shown by Mehen and Stewart\[40]\ to be equivalent to the power divergence subtraction (PDS) scheme proposed by Kaplan, Savage and Wise.\[38]\)

In any case, the would-be linear divergence is, of course, cancelled by introduction of a counterterm accounting for the omitted high energy component of the theory, which renormalizes $C_0$ to $C_0(\mu)$. That $C_0(\mu)$ should be a function of the cutoff is clear because by varying the cutoff energy we are varying the amount of higher energy physics which we are including in our effective description. The scattering amplitude then becomes

$$f(k) = \frac{m_r}{2\pi} \left( \frac{1}{\frac{1}{C_0(\mu)} - G_0(k)} \right) = \frac{1}{\frac{1}{m_r C_0(\mu)} - \frac{2\mu}{\pi} - ik}$$

(42)

Comparing with Eq. 10 we identify the scattering length as

$$-\frac{1}{a_0} = -\frac{2\pi}{m_r C_0(\mu)} - \frac{2\mu}{\pi}$$

(43)

Of course, since $a_0$ is a physical observable, it is cutoff independent, so that the $\mu$ dependence of $1/C_0(\mu)$ is cancelled by the cutoff dependence in the Green’s function.

### 3.4 Coulomb Effects in EFT

More interesting is the case where we restore the Coulomb interaction between the particles. The derivatives in Eq. 36 then become covariant and the bubble sum is evaluated with static photon exchanges between each of the lines—each bubble is replaced by one involving a sum of zero, one, two, etc. Coulomb interactions, as shown in Figure 2.

![Figure 3: The Coulomb corrected bubble.](image)

The net result in the case of same charge scattering is the replacement of the free propagator by its Coulomb analog

$$G_0(k) \rightarrow G^\pm_C(k) = \lim_{\mathbf{r}'\rightarrow 0} \int \frac{d^3s}{(2\pi)^3} \frac{S^+_{\mathbf{r}}(\mathbf{r}') S^+_{\mathbf{r}}(\mathbf{r})}{k^2 - \frac{\mathbf{s}^2}{2m_r} + i\epsilon}$$
\[
\psi^+(\vec{r}) = C(\eta_+ (s)) e^{i\sigma_0} e^{i\vec{s} \cdot \vec{r}} {}_1 F_1 (-i \eta_+ (s), 1, i s \vec{r} - i \vec{s} \cdot \vec{r})
\]

\[ \text{is the outgoing Coulomb wavefunction for repulsive Coulomb scattering.} \]

Also in the initial and final states the influence of static photon exchanges must be included to all orders, which produces the factor \( C^2(2\pi \eta_+ (k)) \exp(2i\sigma_0) \). Thus the repulsive Coulomb scattering amplitude becomes

\[
f^+_C(k) = -\frac{m_r}{2\pi} \frac{C_0 C^2(\eta_+ (k)) \exp 2i\sigma_0}{1 - C_0 G^+_C(k)}
\]

The momentum integration in Eq. 44 can be performed as before using cutoff regularization, yielding

\[
G^+_C(k) = -\frac{m_r}{2\pi} \left\{ \frac{2\mu}{\pi} + \frac{1}{a_B} \left[ H(i\eta_+(k)) - \ln \frac{\mu a_B}{\pi} - \zeta \right] \right\}
\]

where \( \zeta = \ln 2\pi - \gamma \). We have then

\[
f^+_C(k) = \frac{C^2(\eta_+(k)) e^{2i\sigma_0}}{-\frac{2\mu}{m_r C_0(\mu)} - \frac{2\mu}{\pi} - \frac{1}{a_B} \left[ H(i\eta_+(k)) - \ln \frac{\mu a_B}{\pi} - \zeta \right]}
\]

\[
= \frac{C^2(\eta_+(k)) e^{2i\sigma_0}}{-\frac{1}{a_0} - \frac{1}{a_B} \left[ H(i\eta_+(k)) - \ln \frac{\mu a_B}{\pi} - \zeta \right] - i k C^2(\eta_+(k))}
\]

Comparing with Eq. 34 we identify the Coulomb scattering length as

\[
-\frac{1}{a_C} = -\frac{1}{a_0} + \frac{1}{a_B} \left( \ln \frac{\mu a_B}{\pi} + \zeta \right)
\]

which matches nicely with Eq. 32 if a reasonable cutoff \( \mu \sim m_\pi \sim 1/R \) is employed. The scattering amplitude then has the simple form

\[
f^+_C(k) = \frac{C^2(\eta_+(k)) e^{2i\sigma_0}}{-\frac{1}{a_C} - \frac{1}{a_B} H(i\eta_+(k))}
\]

in agreement with Eq. 44.

Before moving to our ultimate goal, which is the parity violating sector, it is useful to spend some additional time focusing on the deuteron state, since this will be used in our forthcoming PV analysis and provides a useful calibration of the precision of our approach.

### 4 The Deuteron

Fermi was fond of asking the question “Where’s the hydrogen atom for this problem?” meaning what is the simple model that elucidates the basic physics
of a given system? In the case of nuclear structure, the answer is clearly the deuteron, and it is essential to have a good understanding of this simplest of nuclear systems at both the qualitative and quantitative levels. The basic static properties which we shall try to understand are indicated in Table 2. Thus, for example, from the feature that the deuteron carries unit spin with positive parity, angular momentum arguments demand that it be constructed from a combination of S- and D-wave components (a P-wave piece is forbidden from parity considerations—more about that later). Thus the wavefunction can be written in the form

$$\psi_d(\vec{r}) = \frac{1}{\sqrt{4\pi}} \left( u_d(r) + \frac{3}{\sqrt{8}} w_d(r) \mathcal{O}_{pn} \right) \chi_t$$

(51)

where $\chi_t$ is the spin-triplet wavefunction and

$$\mathcal{O}_{pn} = \vec{\sigma}_p \cdot \hat{r} \vec{\sigma}_n \cdot \hat{r} - \frac{1}{3} \vec{\sigma}_p \cdot \vec{\sigma}_n$$

is the tensor operator. Here $u_d(r)$, $w_d(r)$ represent the S-wave, D-wave components of the deuteron wavefunction, respectively. We note that

$$\mathcal{O}_{pn}|\uparrow\uparrow> = (\cos^2 \theta - \frac{1}{3}) |\uparrow\uparrow> + \sin^2 \theta e^{i2\phi} |\downarrow\downarrow>$$

$$+ \cos \theta \sin \theta e^{i\phi} (|\uparrow\downarrow> + |\downarrow\uparrow>)$$

(52)

Using

$$\int \frac{d\Omega}{4\pi} \hat{r}_i \hat{r}_j = \frac{1}{3} \delta_{ij}$$

(53)

we find the normalization condition

$$1 = \langle \psi_d | \psi_d > = \int_0^\infty dr \int d\Omega \left[ u_d^2(r) + \frac{9}{8} w_d^2(r) \left( (\cos^2 \theta - \frac{1}{3})^2 + 2 \cos^2 \theta \sin^2 \theta + \sin^4 \theta \right) \right]$$

$$= \int_0^\infty dr \left[ u_d^2(r) + \frac{9}{8} w_d^2(r) (1 - \frac{2}{9} + \frac{1}{9}) \right]$$

$$= \int_0^\infty dr (u_d^2(r) + w_d^2(r))$$

(54)

In lowest order we can neglect the D-wave component $w_d(r)$. Then, in the region outside the range $r_o$ of the NN interaction we must have

$$r > r_o \quad \left( -\frac{1}{M} \frac{d^2}{dr^2} + \frac{\gamma^2}{M} \right) u_d(r) = 0$$

(55)

where $\gamma = 45.3$ MeV is the deuteron binding momentum defined above. The solution to Eq. 55 is given by

$$r > r_0 \quad u_d(r) \sim e^{-\gamma r}$$

(56)
Table 2: Static properties of the deuteron.

| Property                        | Value               |
|---------------------------------|---------------------|
| Binding Energy $E_B$            | 2.223 MeV           |
| Spin-parity $J^P$               | $1^+$               |
| Isospin $T$                     | 0                   |
| Magnetic Dipole Moment $\mu_d$ | 0.856$\mu_N$        |
| Electric Quadrupole Moment $Q_d$| 0.286 efm$^2$       |
| Charge Radius $\sqrt{r_d^2}$   | $\sim$ 2 fm        |

However, since $1/\gamma \sim 4.3 \text{ fm} \gg r_0 \sim 1 \text{ fm}$, it is a reasonable lowest order assumption to assume that the deuteron wavefunction has the form Eq. (56) everywhere, so that we may take

$$\psi_d(r) \sim \sqrt{\gamma} \frac{1}{2\pi} e^{-\gamma r}$$  \hspace{1cm} (57)

Of course, we also must consider scattering states. In this case the asymptotic wavefunctions of the $^3S_1$ and $^1S_0$ states must be of the form

$$\psi^{(+)}(r) \xrightarrow{r \to \infty} e^{i\delta(k)} \frac{e^{ikr}}{kr} \sin(kr + \delta(k)) = \frac{\sin(kr)}{kr} + \frac{e^{ikr}}{r} t(k)$$  \hspace{1cm} (58)

with

$$t(k) = \frac{1}{k} e^{i\delta(k)} \sin \delta(k)$$

being the partial wave transition amplitude. At very low energy we may use the simple effective range approximation defined above

$$k \cot \delta(k) \simeq \frac{1}{a}$$  \hspace{1cm} (59)

to write

$$t(k) \simeq \frac{1}{\frac{1}{a} - ik}$$  \hspace{1cm} (60)

Then we have the representation

$$\psi^{(+)}(r) \xrightarrow{r \to \infty} e^{i\delta(k)} \frac{e^{ikr}}{kr} \sin(kr + \delta(k)) = \frac{\sin(kr)}{kr} + \frac{e^{ikr}}{r} \left( \frac{1}{\frac{1}{a} - ik} \right)$$  \hspace{1cm} (61)

and, comparing with a Green’s function solution to the Schrödinger equation

$$\psi^{(+)}(\vec{r}) = e^{i\vec{K} \cdot \vec{r}} - \frac{M}{4\pi} \int d^3r' \frac{e^{ik|\vec{r} - \vec{r}'|}}{|\vec{r} - \vec{r}'|} U(\vec{r}') \psi(\vec{r}')$$  \hspace{1cm} (62)

we see that the potential at low energy can be represented via the simple local potential

$$U(\vec{r}) \simeq \frac{4\pi}{M} a \delta^3(\vec{r})$$  \hspace{1cm} (63)
which is sometimes called the zero-range approximation (ZRA) and is equivalent to the contact potential used in the EFT approach.

The relation between the scattering and bound state descriptions can be obtained by using the feature that the deuteron wavefunction must be orthogonal to its $^3S_1$ counterpart. This condition reads

$$0 = \int d^3r \psi_d^\dagger(r) \psi_t(r) = \sqrt{8\pi\gamma} \int_0^\infty dr e^{-\gamma r} \left( \frac{1}{k} \sin kr + e^{ikr} t_t(k) \right)$$

$$= \sqrt{8\pi\gamma} \left( \frac{1}{\gamma^2 + k^2} + \frac{1}{\gamma - ik} t_t(k) \right) = \sqrt{8\pi\gamma} \left( \frac{1}{\gamma + ik} + \frac{1}{a_t - ik} \right)$$

which requires that $\gamma = 1/a_t$. This necessity is also clear from the already mentioned feature that the deuteron represents a pole in $t_t(k)$ in the limit as $k \to i\gamma$, i.e., $-1/a_t + \gamma = 0$. Since $1/\gamma \sim 4.3$ fm, this equality holds to within 20% or so and indicates the precision of our approximation. In spite of this roughness, there is much which can be learned from this simple analytic approach.

We begin with the charge radius, which is defined via

$$<r_d^2> = <r_p^2> + \int d^3r \frac{1}{4} r^2 |\psi_d(r)|^2$$

Note here that we have included the finite size of the proton, since it is comparable to the deuteron size and have scaled the wavefunction contribution by a factor of four since $\vec{r}_p = \frac{1}{2} \vec{r}$. Performing the integration, we have

$$\int d^3r \frac{1}{4} r^2 |\psi_d(r)|^2 = \pi \int_0^\infty dr r^2 u^2(r) = \frac{1}{8\gamma^2}$$

and, since $<r_p^2> \simeq 0.65$ fm$^2$ we find

$$\sqrt{<r_d^2>} = \sqrt{0.65 + \frac{1}{8\gamma^2}} \text{ fm} \simeq 1.8 \text{ fm}$$

which is about 10% too low and again indicates the roughness of our approximation.

Now consider the magnetic moment, for which the relevant operator is

$$\vec{M} = \frac{e}{2M} (\mu_p \vec{\sigma}_p + \mu_n \vec{\sigma}_n) + \frac{e}{2M} \vec{L}_p$$

$$= \frac{e}{4M} \left( \vec{J} + \mu_V (\vec{\sigma}_p - \vec{\sigma}_n) + (\mu_S - \frac{1}{2})(\vec{\sigma}_p + \vec{\sigma}_n) \right)$$

where $\vec{J} = \vec{L} + \frac{1}{2}(\vec{\sigma}_p + \vec{\sigma}_n)$ is the total angular momentum, $\mu_V = \mu_p - \mu_n = 4.70$, $\mu_S = \mu_p + \mu_n = 0.88$ are the isovector, isoscalar moments, and the "extra" factor of 1/2 associated with the orbital angular momentum comes from the obvious identity $\vec{L}_p = \vec{L}/2$. We find then

$$\frac{e}{2M} \mu_d = <\psi_d; 1,1|\vec{M}|\psi_d; 1,1> = \frac{e}{4M} [1 + (2\mu_S - 1) <\psi_d; 1,1|\vec{S}|\psi_d; 1,1>$$
\[
= \frac{e}{4M} \left[ 1 + (2\mu S - 1) \int d^3r (u_d^2(r) + \frac{9}{8} w^2(r) \left( \cos^2 \theta - \frac{1}{3} \right)^2 - \sin^4 \theta \right]
= \frac{e}{2M} \left[ \mu S - \frac{3}{2} (\mu S - \frac{1}{2}) \int_0^\infty dr w_d^2(r) \right]
\]

(69)

In the lowest order approximation—neglecting the D-wave component of the deuteron—we find

\[
<1, 1| M_3 | 1, 1> \approx \mu_S e^{2M} \left( \mu S - \frac{3}{2} \right) \left( \mu S - \frac{1}{2} \right) \int_0^\infty dr w_d^2(r)
\]

(70)

and this prediction—\(\mu_d = \mu_S = 0.88\mu_N\)—is in good agreement with the experimental value \(\mu_d^{exp} = 0.856\mu_N\).

### 4.1 D-Wave Effects

A second static observable is the quadrupole moment \(Q_d\), which is a measure of deuteron oblateness. In this case a pure S-wave picture predicts a spherical shape so that \(Q_d = 0\). Thus, in order to generate a quadrupole moment, we must introduce a D-wave piece of the wavefunction. Now, just as we related the \(\ell = 0\) wavefunction to the np scattering in the spin triplet state, we can relate the D-wave component to the scattering amplitude provided we include spin. Thus, if we write the general scattering matrix consistent with time reversal and parity-conservation as

\[
\mathcal{M}(\vec{k}', \vec{k}) = \alpha + \beta \vec{\sigma}_p \cdot \hat{n} \vec{\sigma}_n \cdot \hat{n} + \rho (\vec{\sigma}_p + \vec{\sigma}_n) \cdot \hat{n} + (\kappa + \lambda) \vec{\sigma}_p \cdot \hat{n} \vec{\sigma}_n \cdot \hat{n} + (\kappa - \lambda) \vec{\sigma}_p \cdot \hat{n} \vec{\sigma}_n \cdot \hat{n}
\]

(71)

where

\[
\hat{n}_\pm = \frac{\vec{k} \pm \vec{k}'}{|\vec{k} \pm \vec{k}'|}, \quad \hat{n} = \frac{\vec{k} \times \vec{k}'}{|\vec{k} \times \vec{k}'|},
\]

we can represent the asymptotic scattering wavefunction via

\[
\psi(r) \xrightarrow{r \to \infty} e^{ikr} + \mathcal{M}(-i\vec{\nabla}, \vec{k}) \frac{e^{ikr}}{r}
\]

(72)

A useful alternative form for \(\mathcal{M}\) can be found via the identity

\[
\vec{\sigma}_p \cdot \hat{n} \vec{\sigma}_n \cdot \hat{n} = \vec{\sigma}_p \cdot \vec{\sigma}_n - \vec{\sigma}_p \cdot \hat{n} \vec{\sigma}_n \cdot \hat{n} - \vec{\sigma}_p \cdot \hat{n} \vec{\sigma}_n \cdot \hat{n}
\]

(73)

and, using the deuteron spin vector \(\vec{S} = \frac{1}{2} (\vec{\sigma}_p + \vec{\sigma}_n)\), it is easy to see that

\[
\mathcal{M}(\vec{k}', \vec{k}) = -a_t + \frac{1}{M^2} \left[ c' \vec{S} \cdot \vec{k} \times \vec{k}' + g_1 (\vec{S} \cdot (\vec{k} + \vec{k}'))^2 + g_2 (\vec{S} \cdot (\vec{k} - \vec{k}'))^2 \right]
\]

(74)

where

\[
c' = \frac{2\rho M^2}{k^2 \sin \theta}, \quad g_1 = \frac{(\kappa - \beta + \lambda)M^2}{2k^2 \cos^2 \frac{\theta}{2}}, \quad g_2 = \frac{(\kappa - \beta - \lambda)M^2}{2k^2 \sin^2 \frac{\theta}{2}}
\]
Then, since in the ZRA
\[ \vec{k}' \rightarrow -i\nabla \delta^3(\vec{r}), \quad \vec{k} \rightarrow \delta^3(\vec{r}) \cdot -i\nabla \]
we find the effective local potential
\[
U(\vec{r}) = \frac{4\pi}{M} \left[ a_t \delta^3(\vec{r}) + \frac{\vec{e}'}{M^2} \epsilon_{ijk} S_i \nabla_j \delta^3(\vec{r}) \nabla_k \right. \\
+ \left. \frac{1}{2M^2} S_{ij} \left( (g_1 + g_2) \{ \nabla_i, \nabla_j, \delta^3(\vec{r}) \} + (g_1 - g_2) (\nabla_i \delta^3(\vec{r}) \nabla_j + \nabla_j \delta^3(\vec{r}) \nabla_i) \right) \right]
\]
(76)
where
\[ S_{ij} = S_i S_j + S_j S_i - \frac{4}{3} \delta_{ij} \]  
(77)
Using the Green’s function representation—Eq. 72, the asymptotic form of the triplet scattering wavefunction becomes
\[
\psi(r) \xrightarrow{r \to \infty} e^{i\vec{k} \cdot \vec{r}} - \left( a_t + \frac{g_1 + g_2}{2M^2} S_{ij} \nabla_i \nabla_j \right) \frac{e^{ikr}}{r} \chi_t
\]  
(78)
and, by continuing to the value \( k \rightarrow i\gamma \), we can represent the deuteron wavefunction as
\[
\psi_d(r) \sim \sqrt{\frac{\gamma}{2\pi}} \left( 1 + \frac{g_1 + g_2}{2M^2 a_t} S_{ij} \nabla_i \nabla_j \right) \frac{1}{r} e^{-\gamma r} \chi_t
\]  
(79)
A little work shows that this can be written in the equivalent form
\[
\psi_d(r) \sim \sqrt{\frac{\gamma}{2\pi}} \left[ 1 + \frac{g_1 + g_2}{2M^2 a_t} O_{pn} \left( \frac{d^2}{dr^2} - \frac{1}{r} \frac{d}{dr} \right) \right] \frac{1}{r} e^{-\gamma r} \chi_t
\]
\[ = \sqrt{\frac{\gamma}{2\pi}} \left[ 1 + \frac{g_1 + g_2}{2M^2 a_t} O_{pn} \left( \frac{3}{r^2} + \frac{3\gamma}{r} + \gamma^2 \right) \right] \frac{1}{r} e^{-\gamma r} \chi_t
\]  
(80)
Here the asymptotic ratio of S- and D-wave amplitudes is an observable and is denoted by
\[ \eta = \frac{A_D}{A_S} = \frac{\sqrt{2}(g_1 + g_2)}{3M^2 a_t^2} \]  
(81)
This quantity has been determined experimentally from elastic dp scattering and from neutron stripping reactions to be\(^{11}\)
\[ \eta = 0.0271 \pm 0.0004, \quad i.e., \quad g_1 + g_2 = 105 \text{ fm} \]
Defining the quadrupole operator\(^1\)
\[ Q_{ij} \equiv \frac{e}{4} (3r_i r_j - \delta_{ij} r^2) \]
\(^1\)Note that the factor of \( \frac{1}{4} \) arises from the identity \( r^2 = \frac{1}{2} r^2 \)
and using
\[ \int \frac{d\Omega}{4\pi} \hat{r}_i \hat{r}_j \hat{r}_k \hat{r}_\ell = \frac{1}{15} (\delta_{ij} \delta_{k\ell} + \delta_{i\ell} \delta_{jk} + \delta_{ik} \delta_{j\ell}) \] (82)
we note
\[ \int d^3r \psi^*_d(r) Q_{ij} \psi_d(r) \simeq 2e \int d^3r \chi^\dagger \left( \frac{3}{r^3} + \frac{3\gamma}{r^2} + \frac{\gamma^2}{r} \right) u(r) \chi \]
\[ = \frac{3e}{2} \frac{1}{15} \frac{g_1 + g_2}{2M^2} \chi^\dagger \left( \sigma_{pi} \sigma_{nj} + \sigma_{pj} \sigma_{ni} - \frac{2}{3} \delta_{ij} \vec{\sigma}_p \cdot \vec{\sigma}_n \right) \chi \]
\[ \times 4\pi \int_0^\infty dr e^{-2\gamma r} \left( 3 + 3\gamma r + \gamma^2 r^2 \right) \]
\[ = \frac{1}{5} \frac{e(g_1 + g_2)\gamma^2}{2M^2} \chi^\dagger \left( \sigma_{pi} \sigma_{nj} + \sigma_{pj} \sigma_{ni} - \frac{2}{3} \delta_{ij} \vec{\sigma}_p \cdot \vec{\sigma}_n \right) \chi \left( \frac{3}{2\gamma} + \frac{3\gamma}{(2\gamma)^2} + \frac{2\gamma^2}{(2\gamma)^3} \right) \]
\[ = \frac{e(g_1 + g_2)\gamma}{4M^2} \chi^\dagger \left( \sigma_{pi} \sigma_{nj} + \sigma_{pj} \sigma_{ni} - \frac{2}{3} \delta_{ij} \vec{\sigma}_p \cdot \vec{\sigma}_n \right) \chi \] (83)

Then the quadrupole moment is found to be
\[ Q_d^{th} = \langle \psi_d; 1, 1 | Q_{zz} | \psi_d; 1, 1 \rangle = \frac{e(g_1 + g_2)}{3\mu_1 M^2} \simeq 0.28 e \text{ fm}^2, \] (84)
in good agreement with the experimental value
\[ Q_d^{exp} = 0.286 e \text{ fm}^2 \]

From its definition, we observe that the quadrupole moment would vanish for a spherical (purely S-wave) deuteron and that a positive value indicates a slight elongation along the spin axis.

Note that in interpreting the meaning of the D-wave piece of the deuteron wavefunction one often sees things described in terms of the D-state probability

\[ P_D = \int_0^\infty dr w^2(r) \]

However, since
\[ \int d^3r \left( \frac{3}{r^2} + \frac{3\gamma}{r} + \gamma^2 \right)^2 \exp(-2\gamma r) \] (85)
diverges while in reality the D-wave function \( w_d(r) \) must vanish as \( r \to 0 \), it is clear that the connection between the asymptotic amplitude \( \eta \) and the D-state probability \( P_D \) must be model dependent. Nevertheless, the D-state piece is a small but important component of the deuteron wavefunction. As one indication of this, let’s return to the magnetic moment calculation and insert the D-wave contribution. We find then
\[ \mu_d = \mu_S - \frac{3}{2} (\mu_S - \frac{1}{2}) P_D \] (86)
If we insert the experimental value \( \mu_d = 0.857 \) we find \( P_D \approx 0.04 \) which can now be used in other venues. However, it should be kept in mind that this analysis is only approximate, since we have neglected relativistic corrections, meson exchange currents, etc.

Of course, static properties represent only one type of probe of deuteron structure. Another is provided by the use of electromagnetic interactions, for which a well-studied case is photodisintegration—\( \gamma d \to np \)—or radiative capture—\( np \to d\gamma \)—which are related by time reversal invariance.

5 Parity Conserving Electromagnetic Interaction: 
\( np \leftrightarrow d\gamma \)

An important low energy probe of deuteron structure can be found within the electromagnetic transition \( np \leftrightarrow d\gamma \). Here the np scattering states include both spin-singlet and -triplet components and we must include a bound state—the deuteron. For simplicity, we represent the latter by purely the dominant S-wave component, which has the form

\[
\psi_d(r) = \sqrt{\frac{1}{2\pi r}} e^{-\gamma r}, \quad \text{or} \quad \psi_d(q) = \sqrt{\frac{8\pi\gamma}{\gamma^2 + q^2}} \tag{87}
\]

Since we are considering an electromagnetic transition at very low energy we can be content to include only the lowest—E1, M1, and E2—multipoles, which are described by the Hamiltonian\[42\]

\[
H = e\sigma_0 \hat{e}_\gamma \cdot \left[ \pm \frac{\mathbf{r}}{2} - \frac{1}{4M} \hat{s}_\gamma \times \left( \mu_V (\hat{s}_p - \hat{s}_n) + \mu_S - \frac{1}{2} (\hat{s}_p + \hat{s}_n) \right) - \frac{i}{8} \mathbf{r} \cdot \mathbf{k} \right] \tag{88}
\]

Here \( \hat{s}_\gamma \) is the photon momentum, \( \mu_V, \mu_S = \mu_p \pm \mu_n \) are the isoscalar, isovector magnetic moments, and we have used Siegert’s theorem to convert the conventional \( \hat{p} \cdot \hat{A}/M \) interaction into the E1 form given above.\[2\] The \( \pm \) in front of the E1 operator depends upon whether the \( np \to d\gamma \) or \( \gamma d \to np \) reaction is under consideration. The electromagnetic transition amplitude then can be written in the form

\[
\text{Amp} = \chi_i \left[ \hat{e}_\gamma \times \hat{s}_\gamma \cdot (G_{M1V}(\hat{s}_p - \hat{s}_n) + G_{M1S}(\hat{s}_p + \hat{s}_n)) + G_{E1}(\hat{e}_\gamma \cdot \hat{k} + G_{E2}(\hat{s}_p \cdot \hat{e}_\gamma \hat{s}_n + \hat{s}_n \cdot \hat{e}_\gamma \hat{s}_p) \right] \chi_i \tag{89}
\]

The leading parity-conserving transition at near-threshold energy is then the isovector M1 amplitude—\( G_{M1V} \)—which connects the \( ^3S_1 \) deuteron to the \( ^1S_0 \) scattering state of the np system. From Eq. \[SS\] we identify

\[
G_{M1V} = \frac{e\sigma_0 \mu_V}{4M} \int d^3 r \psi_{^3S_1}(kr) \psi_d(r) \tag{90}
\]

\[2\] Note that the factor of two (eight) in the E1 (E2) component arises from the obvious identity \( r_p \to \frac{1}{2} r_p \).
Using the asymptotic form
\[
\psi_{1S_0}^{(-)}(kr) = \frac{e^{-i\delta_s}}{kr} (\sin kr \cos \delta_s + \cos kr \sin \delta_s)
\] (91)
the radial integral becomes
\[
\int d^3r \psi_{1S_0}^{(-)*}(kr) \psi_d(r) = \frac{4\pi e^{i\delta_s}}{k} \int_0^\infty (\sin kr \cos \delta_s + \cos kr \sin \delta_s) e^{-\gamma r} \, dr
\]
\[
= \frac{4\pi e^{i\delta_s}}{k(k^2 + \gamma^2)} (k \cos \delta_s + \gamma \sin \delta_s)
\] (92)
Since by energy conservation
\[
s_0 = \frac{k^2 + \gamma^2}{M}
\]
we can use the lowest order effective range values for the scattering phase shift to this result in the form
\[
G_{M1V} = \frac{e\mu V \sqrt{8\pi\gamma} e^{-it\tan^{-1}k a_s}(1 - \gamma a_s)}{4M \sqrt{1 + k^2 a_s^2}}
\] (93)
Note here that the phase of the amplitude is required by the Fermi-Watson theorem, which follows from unitarity.

The M1 cross section is then found by squaring and multiplying by phase space. In the case of radiative capture this is found to be
\[
\Gamma_{np \to d\gamma} = \frac{1}{|\vec{v}_{rel}|} \int \frac{d^3s}{(2\pi)^3 2s_0} 2\pi \delta(s_0 - \frac{\gamma^2}{M} - \frac{k^2}{M}) \sum_{\lambda, \gamma} \frac{1}{4} \text{Tr} P_{1T} T^\dagger
\] (94)
Here
\[
\sum_{\lambda, \gamma} \frac{1}{4} \text{Tr} P_{1T} T^\dagger = \frac{|G_{M1V}|^2}{4} \text{Tr} \left( 3 + \hat{\sigma}_1 \cdot \hat{\sigma}_2 \right) \hat{\epsilon}_\gamma \times \hat{s}_\gamma \cdot (\hat{\sigma}_p - \hat{\sigma}_n) \hat{\epsilon}_\gamma \times \hat{s}_\gamma \cdot (\hat{\sigma}_p - \hat{\sigma}_n)
\]
\[
= \sum_{\lambda, \gamma} |G_{M1V}|^2 \hat{\epsilon}_\gamma \times \hat{s}_\gamma \cdot \hat{\epsilon}_\gamma \times \hat{s}_\gamma = 2|G_{M1V}|^2
\] (95)
yielding
\[
\sigma_{M1}(np \to d\gamma) = \frac{s_0}{2\pi|\vec{v}_{rel}|} 2|G_{M1V}|^2 = \frac{2\pi\alpha\mu V^2 \gamma(1 - \gamma a_s)(k^2 + \gamma^2)}{M^5(1 + k^2 a_s^2)}
\] (96)
Putting in numbers we find that for an incident thermal neutrons with relative velocity $|\vec{v}_{rel}| = 2200$ m/sec. the predicted cross section is about 300 mb which is about 10% smaller than the experimental value
\[
\sigma_{exp} = 334 \pm 0.1 \text{ mb}
\]
Figure 4: EFT diagrams used in order to calculate the radiative capture reaction $np \rightarrow d\gamma$.

The discrepancy is due to our omission of two-body effects (meson exchange currents) as shown by Riska and Brown\textsuperscript{[45]}.

In a corresponding EFT description of this process, we must calculate the diagrams shown in Figure 1. There is a subtlety here which should be noted. Strictly speaking, as shown by Kaplan, Savage, and Wise\textsuperscript{[46]} the symbol $\otimes$ in these diagrams should be interpreted as creation or annihilation of the deuteron with wavefunction renormalization

$$\sqrt{Z} = \left( \frac{d\Sigma(E)}{dE} \right)^{-\frac{1}{2}}_{E=-B}$$

followed by propagation via

$$\frac{1}{k^2 + M^2 + \gamma^2}$$

However, since in lowest order we have

$$\left( \frac{d\Sigma(E)}{dE} \right)^{-\frac{1}{2}}_{E=-B} = \frac{\sqrt{8\pi\gamma}}{M}$$

we find for the product

$$\sqrt{Z} \cdot \frac{1}{k^2 + \frac{M^2}{M^2}} = \frac{\sqrt{8\pi\gamma}}{k^2 + \gamma^2}$$

which is the deuteron wavefunction in momentum space. Thus in our discussion below we shall use this substitution rather than writing the wavefunction
normalization times propagator product. From Figure 4a then we find

\[ G_{M1V}^a = \frac{e\sigma_0 \mu V}{4M} \int \frac{d^3q}{(2\pi)^3} \psi_{k}^{(0)*}(\vec{q})\psi_d(\vec{q}) \]  \hspace{1cm} (100)

Since \( \psi_{k}^{(0)*}(\vec{q}) = (2\pi)^3 \delta^3(\vec{k} - \vec{q}) \) we have

\[ G_{M1V}^a = \frac{e\sigma_0 \mu V}{4M} \frac{\sqrt{8\pi\gamma}}{\gamma^2 + k^2} \]  \hspace{1cm} (101)

On the other hand from Figures 4b+c we find

\[ G_{M1V}^{b+c} = \frac{e\sigma_0 \mu V}{4M} \left( \frac{C_{0s}}{1 - C_{0s}G_0(k)} \right)^* \int \frac{d^3q}{(2\pi)^3} G_0(\vec{r} = 0, \vec{q})\psi_d(\vec{q}) \]  \hspace{1cm} (102)

Since

\[ G_0(\vec{r} = 0, \vec{q}) = \frac{1}{\frac{\vec{k}}{M} - \frac{\vec{q}}{M} + i\epsilon} \]  \hspace{1cm} (103)

this becomes

\[ G_{M1V}^{b+c} = \frac{e\sigma_0 \mu V}{4M} \left( \frac{C_{0s}}{1 - C_{0s}G_0(k)} \right)^* \int \frac{d^3q}{(2\pi)^3} \frac{\sqrt{8\pi\gamma}}{\gamma^2 + k^2} (G_0(k) - G_0(i\gamma)) \]

\[ = \frac{e\sigma_0 \mu V}{4M} \left( \frac{C_{0s}}{1 - C_{0s}G_0(k)} \right)^* \frac{\sqrt{8\pi\gamma}}{\gamma^2 + k^2} M \frac{-ik - \gamma}{\sqrt{8\pi\gamma}} (104) \]

Adding the two contributions we have

\[ G_{M1V} = \frac{e\sigma_0 \mu V}{4M} \frac{\sqrt{8\pi\gamma}}{\gamma^2 + k^2} \left[ 1 - \left( \frac{-\gamma - ik}{a_s} \right) \right] \]

\[ = \frac{e\sigma_0 \mu V}{4M} \frac{\sqrt{8\pi\gamma}}{\gamma^2 + k^2} \left( \frac{1 - \gamma a_s}{1 + ika_s} \right) \]  \hspace{1cm} (105)

which agrees completely with Eq. 93 obtained via conventional coordinate space procedures. Of course, we still have a \( \sim 10\% \) discrepancy with the experimental cross section, which is handled by inclusion of a four-nucleon M1 counterterm connecting \( ^3S_1 \) and \( ^1S_0 \) states—

\[ L_{2}^{EM} = eL_1^{M1V}(N^T \vec{P} \cdot \vec{B} N)^\dagger(N^{T} P_3 N) \]  \hspace{1cm} (106)

where here the \( P_i \) represent relevant projection operators.[17]

As the energy increases above threshold, it is necessary to include the corresponding P-conserving E1 multipole—

\[ \text{Amp} = G_{E1} \bar{\epsilon} \cdot \vec{k} \chi^\dagger \chi_t \]  \hspace{1cm} (107)
In this case the matrix element involves the np \(^3\text{P}\)-wave final state and, neglecting final state interactions in this channel, the matrix element is given by

\[
G_{E1\vec{k}} = \frac{e s_0}{2} \int d^3 r \psi_k^{(0)*}(r) \bar{\psi}_d(r)
\]  

(108)

The radial integral can be found via

\[
- ik \cdot \int d^3 r e^{-i\vec{k} \cdot \vec{r}} \tilde{\psi}_d(r) = \frac{d}{d\lambda_{\lambda=1}} \frac{2 \gamma}{2\pi} \int d^3 r e^{-i\vec{k} \cdot \vec{r}} \frac{1}{r} r^{-\gamma} = \frac{d}{d\lambda_{\lambda=1}} \frac{\sqrt{8\pi\gamma}}{\gamma^2 + k^2 \lambda^2} = -\frac{2k^2 \sqrt{8\pi\gamma}}{(k^2 + \gamma^2)^2}
\]

(109)

Equivalently using EFT methods we have

\[
\int \frac{d^3 q}{(2\pi)^3} \psi_k^{(0)*}(\vec{q}) \vec{\nabla} \tilde{\psi}_d(q) = -2i \sqrt{8\pi\gamma} \frac{k}{(k^2 + \gamma^2)^2}
\]

(110)

In either case

\[
G_{E1} = -\frac{ie s_0 \sqrt{8\pi\gamma}}{(k^2 + \gamma^2)^2}
\]

(111)

and the corresponding cross section is

\[
\sigma_{E1}(np \rightarrow d\gamma) = \frac{1}{4\pi |\vec{v}_{rel}|} \int d^3 k \frac{3s_0}{4\pi} (\vec{k} \cdot \hat{k} - (\vec{k} \cdot \hat{s})^2) \frac{e^2 8\pi\gamma s_0^2}{(k^2 + \gamma^2)^4}
\]

\[
= \frac{8\pi\alpha k^2 \gamma}{|\vec{v}_{rel}| M^3 (k^2 + \gamma^2)}
\]

(112)

It is important to note that we can easily find the corresponding photodisintegration cross sections by multiplying by the appropriate phase space. For unpolarized photons we have

\[
\sigma(\gamma d \rightarrow np) = \frac{1}{3 \cdot 2 \cdot 2} \frac{1}{2s_0} \int \frac{d^3 k}{(2\pi)^3} \sum_{\lambda, \gamma} 2\pi \delta(s_0 - \gamma^2 - \frac{k^2}{M}) |\text{Amp}|^2
\]

\[
= \frac{M k}{24\pi s_0} \sum_{\lambda, \gamma} \int \frac{d\Omega_{\vec{k}}}{4\pi} |\text{Amp}|^2
\]

(113)

Using the results obtained above for radiative capture—

\[
\sum_{\lambda, \gamma} |\text{Amp}|^2 = 8|M_{M1V}|^2 + 3(\vec{k} \cdot \hat{k} - (\vec{k} \cdot \hat{s})^2) |G_{E1}|^2
\]

(114)

we find the photodisintegration cross sections to be

\[
\sigma_{M1}(\gamma d \rightarrow np) = \frac{2\pi \alpha}{3M^2} \frac{(1 - a_s \gamma)^2 \mu_1^2 k \gamma}{(k^2 + \gamma^2)(1 + k^2 a_0^2)}, \quad \sigma_{E1}(\gamma d \rightarrow np) = \frac{8\pi\alpha \gamma k^3}{3(k^2 + \gamma^2)^3}
\]

(115)
Although the leading electromagnetic physics is controlled, as we have seen, by the isovector M1 and E1 amplitudes, there exist small but measurable isoscalar M1 and E2 transitions\[48],[49],[50]. In the former case the transition is between the S-wave (D-wave) deuteron ground state and into the $^3S_1(^3D)$ scattering state. The amplitude $G_{M1S}$ is small because of the smallness of $\mu_S - \frac{1}{2}$ and because of the orthogonality restriction. In the case of $G_{E2}$, the result is suppressed by the requirement for transfer of two units of angular momentum, so that the transition must be between S- and D-wave components of the wavefunction.

We first evaluate the isoscalar M1 amplitude, which from Eq. 88 is given by (cf. Eq. 69)

$$G_{M1S} = \frac{e}{2M}(\mu_S - \frac{1}{2})<\psi_d;1,1|S_3|\psi_d,1,1>$$

$$= \frac{e}{2M}(\mu_S - \frac{1}{2})\int_0^\infty dr(u_d(r)u_t(r) - \frac{1}{2}w_d(r)w_t(r))$$

$$= -\frac{e}{2M}(\mu_S - \frac{1}{2})\frac{3}{2}\int_0^\infty drw_t(r)w_d(r)$$

(116)

where the last form was found using the orthogonality condition. In order to estimate the latter, we follow Danilov in assuming that, since the radial integral is short-distance dominated, the D-wave deuteron and scattering pieces are related by a simple constant\[51], which, using orthogonality, must be given by

$$w_t(r) \simeq -a_t\sqrt{\frac{2\pi}{\gamma}}w_d(r)$$

(117)

The matrix element then becomes

$$G_{M1S} \simeq \frac{e}{2M}(\mu_S - \frac{1}{2})\frac{3}{2}P_Da_t$$

(118)

Likewise, using Eq. 82 we note that

$$\int d^3r \left( \frac{1}{r}u_t(r) + \frac{3}{\sqrt{8}}O_{pn}w_t(r) \right) \vec{r} \cdot \hat{\epsilon}_\gamma \vec{r} \cdot \hat{s}_\gamma |\psi_d(r)\rangle$$

$$= \frac{3}{\sqrt{8}15}\int_0^\infty drr^2(u_t(r)w_d(r) + w_t(r)u_d(r)) [\vec{\sigma}_p \cdot \hat{\epsilon}_\gamma \vec{\sigma}_n \cdot \hat{s}_\gamma + \vec{\sigma}_n \cdot \hat{\epsilon}_\gamma \vec{\sigma}_p \cdot \hat{s}_\gamma]$$

(119)

so that the corresponding E2 coupling is found to be

$$G_{E2} = \frac{e\sigma}{80\sqrt{2}}\int_0^\infty drr^2(u_t(r)w_d(r) + w_t(r)u_d(r)) = -\frac{e\sigma}{80\sqrt{2}}\frac{g_1 + g_2}{2M^2}$$

(120)

In order to detect these small components we can use the circular polarization induced in the final state photon by an initially polarized neutron, which is found to be

$$P_\gamma = -2 \left( \frac{G_{M1S} - G_{E2}}{G_{M1V}} \right)$$

(121)
Putting in numbers we find
\[
P_\gamma = P_\gamma(M1) + P_\gamma(E2) \\
= \frac{-\gamma a_t}{\mu_V(1 - \gamma a_s)} \left( \mu_S - \mu_d + \frac{2 \gamma^2 (g_1 + g_2)}{15 a_s M^2} \right) \\
\approx -1.17 \times 10^{-3} - 0.24 \times 10^{-3} \\
= -1.41 \times 10^{-3}
\]
which is in reasonable agreement with the experimental value\[52\]
\[
P_\gamma^{exp} = (-1.5 \pm 0.3) \times 10^{-3}
\]

Having familiarized ourselves with the analytic techniques which are needed, we now move to our main subject, which is hadronic parity violation in the NN system.

6 Parity-Violating NN Scattering

For simplicity we begin again with a system of two nucleons. Then the NN scattering-matrix can be written at low energies in the phenomenological form\[51\]
\[
M(\vec{k}', \vec{k}) = m_t(k) P_1 + m_s(k) P_0
\]
where
\[
P_1 = \frac{1}{4} (3 + \vec{\sigma}_1 \cdot \vec{\sigma}_2), \quad P_0 = \frac{1}{4} (1 - \vec{\sigma}_1 \cdot \vec{\sigma}_2)
\]
are spin-triplet, -singlet spin projection operators and
\[
m_t(k) = \frac{-a_t}{1 + ika_t}, \quad m_s(k) = \frac{-a_s}{1 + ika_s}
\]
are the S-wave partial wave amplitudes in the lowest order effective range approximation, keeping only the scattering lengths $a_t, a_s$. Here the scattering cross section is found via
\[
\frac{d\sigma}{d\Omega} = \text{Tr} M^\dagger M
\]
so that at the lowest energy we have the familiar form
\[
\frac{d\sigma_{s,t}}{d\Omega} = \frac{|a_{s,t}|^2}{1 + k^2 a_{s,t}^2}
\]
The corresponding scattering wavefunctions are then given by
\[
\psi_k^{(+)}(\vec{r}) = \left[ e^{i\vec{k} \cdot \vec{r}} - \frac{M}{4\pi} \int d^3r' \frac{e^{i|\vec{k} - \vec{r}'|}}{|\vec{r} - \vec{r}'|} U(\vec{r}') \psi_k^{(+)}(\vec{r}') \right] \chi \\
\rightarrow_{\vec{r} \to \infty} \left[ e^{i\vec{k} \cdot \vec{r}} + \mathcal{M}(-i\vec{\nabla}, \vec{k}) \frac{e^{i|\vec{k}r|}}{r} \right] \chi
\]
where $\chi$ is the spin function. In Born approximation we can represent the wavefunction in terms of an effective delta function potential

$$U_{t,s}(\mathbf{r}) = \frac{4\pi}{\mathcal{M}}(a_t P_1 + a_s P_0)\delta^3(\mathbf{r})$$

as can be confirmed by substitution into Eq. (128).

### 6.1 Including the PV Interaction

Following Danilov,[51] we can introduce parity mixing into this simple representation by generalizing the scattering amplitude to include P-violating structures. Up to laboratory energies of 50 MeV or so, we can omit all but S- and P-wave mixing, in which case there exist only five independent such amplitudes:

i) $d_t(k)$ representing $^3S_1 - ^1P_1$ mixing;

ii) $d_0^{0,1,2}(k)$ representing $^1S_0 - ^3P_0$ mixing with $\Delta I = 0, 1, 2$ respectively;

iii) $c_t(k)$ representing $^3S_1 - ^3P_1$ mixing.

After a little thought, it becomes clear then that the low energy scattering-matrix in the presence of parity violation can be written as

$$\mathcal{M}(\mathbf{k}', \mathbf{k}) = \left[ m_s(k) P_0 + c_t(k) (\vec{\sigma}_1 + \vec{\sigma}_2) \cdot (\vec{k}' + \vec{k}) \frac{1}{2} (\tau_1 - \tau_2)_z 
+ (\vec{\sigma}_1 - \vec{\sigma}_2) \cdot (\vec{k}' + \vec{k}) \left( P_0 d_0^0(k) + \frac{1}{2} (\tau_1 + \tau_2)_z d_1^3(k) + \frac{3 \tau_1 z \tau_2 - \tau_1 \cdot \tau_2}{28} d^2_s(k) \right) \right] P_1$$

Note that since under spatial inversion—$\vec{\sigma} \rightarrow -\vec{\sigma}, \vec{k}, \vec{k}' \rightarrow -\vec{k}, -\vec{k}'$—each of the new pieces is P-odd, and since under time reversal—$\vec{\sigma} \rightarrow -\vec{\sigma}, \vec{k}, \vec{k}' \rightarrow -\vec{k}', -\vec{k}$—the terms are each T-even. At very low energies the coefficients in the T-matrix become real and we define

$$\lim_{k \rightarrow 0} m_{s,t}(k) = a_{s,t}, \quad \lim_{k \rightarrow 0} c_t(k), d_s(k), d_t(k) = \rho_t a_t, \lambda_s^t a_s, \lambda_t a_t$$

(The reason for factoring out the S-wave scattering length will be described presently.) The five real numbers $\rho_t, \lambda_s^t, \lambda_t$ then completely characterize the low energy parity-violating interaction and can in principle be determined experimentally, as we shall discuss below.\(^3\) Alternatively, we can write things in terms of the equivalent notation

$$\lambda_s^{pp} = \lambda_s^0 + \lambda_s^1 + \frac{1}{\sqrt{6}} \lambda_s^2$$

\(^3\)Note that there exists no singlet analog to the spin-triplet constant $c_t$ since the combination $\vec{\sigma}_1 + \vec{\sigma}_2$ is proportional to the total spin operator and vanishes when operating on a spin singlet state.
\[
\begin{align*}
\lambda_s^{np} &= \lambda_s^0 - \frac{2}{\sqrt{6}}\lambda_s^2 \\
\lambda_s^{nn} &= \lambda_s^0 - \lambda_s^1 + \frac{1}{\sqrt{6}}\lambda_s^2
\end{align*}
\] (132)

We can also represent this interaction in terms of a simple effective NN potential. Integrating by parts, we have

\[
\int d^3r e^{ik|\vec{r} - \vec{r}'|} \{ -i\vec{\nabla}, \delta^3(\vec{r'}) \} e^{i\vec{k} \cdot \vec{r}} = (-i\vec{\nabla} + \vec{k}) e^{i\vec{k} \cdot \vec{r}}
\] (133)

which represents the parity-violating admixture to the scattering wavefunction in terms of an S-wave admixture to the scattering P-wave state—\( \sim \vec{\sigma} \cdot \vec{r} e^{i\vec{k} \cdot \vec{r}} \) plus a P-wave admixture the scattering S-state—\( \sim -i\vec{\sigma} \cdot \vec{\nabla} e^{i\vec{k} \cdot \vec{r}} \). We see then that the scattering wave function can be described via

\[
U(\vec{r}) = \frac{4\pi}{M} \left[ \left( a_t \delta^3(\vec{r}) + \lambda_0 a_t(\vec{\sigma}_1 - \vec{\sigma}_2) \cdot \{ -i\vec{\nabla}, \delta^3(\vec{r}) \} \right) P_1 \\
+ a_s \delta^3(\vec{r}) P_0 + \rho_t a_t(\vec{\sigma}_1 + \vec{\sigma}_2) \cdot \{ -i\vec{\nabla}, \delta^3(\vec{r}) \} \frac{1}{2} (\tau_1 - \tau_2)_z \\
+ (\vec{\sigma}_1 - \vec{\sigma}_2) \cdot \{ -i\vec{\nabla}, \delta^3(\vec{r}) \} a_s \left( P_0 \lambda_s^0 + \frac{1}{2} (\tau_1 + \tau_2)_z \lambda_s^1 + \frac{3\tau_1 \tau_2 - \vec{r}_1 \cdot \vec{r}_2}{2\sqrt{6}} \lambda_s^2 \right) \right]
\] (134)

However, before application of this effective potential we must worry about the stricture of unitarity, which requires that

\[
2\text{Im}T = T^\dagger T
\] (135)

In the case of the S-wave partial wave amplitude \( m_t(k) \) this condition reads

\[
\text{Im} m_t(k) = k |m_t(k)|^2
\] (136)

and requires the form

\[
m_t(k) = \frac{1}{k} e^{i\phi_t(k)} \sin \delta_t(k)
\] (137)

Since at zero energy we have

\[
\lim_{k \to 0} m_t(k) = -a_t
\] (138)

It is clear that unitarity can be enforced by modifying this lowest order result via

\[
m_t(k) = \frac{-a_t}{1 + ika_t}
\] (139)

which is the lowest order effective range result. Equivalently, this can easily be derived in an effective field theory (EFT) formalism. In this case the lowest order contact interaction

\[
T_{0t} = C_{0t}(\mu)
\] (140)
becomes, when summed to all orders in the scattering series,
\[ T_t(k) = \frac{C_{0t}(\mu)}{1 - C_{0t}(\mu)G_0(k)} = -\frac{M}{4\pi} \frac{1}{\text{MC}_{0t}(\mu) - \mu - ik} \] (141)

Identifying the scattering length via
\[ -\frac{1}{a_t} = -\frac{4\pi M}{C_{0t}(\mu)} - \mu \] (142)
and noting the relation \( m_t(k) = -\frac{M}{4\pi} T_t(k) \) connecting the scattering and transition matrices, we see that Eqs. 139 and 141 are identical.

So far, so good. However, things become more interesting in the case of the parity-violating transitions. In this case the requirement of unitarity reads, e.g., for the case of scattering in the \( ^3S_1 \) channel
\[ \text{Im} \ d_t(k) = k(m_t^*(k)d_t(k) + d_t^*(k)m_p(k)) \] (143)
where \( m_p(k) \) is the \( ^1P_1 \) analog of the \( m_t(k) \). Eq. (143) is satisfied by the solution
\[ d_t(k) = |d_t(k)|e^{i(\delta_{S_1}(k) + \delta_{P_1}(k))} \] (144)
i.e., the phase of the amplitude should be the sum of the strong interaction phases in the incoming and outgoing channels. At very low energy we can neglect P-wave scattering, and can write
\[ c_t(k) \simeq \rho_t m_t(k), \quad d_t^*(k) \simeq \lambda_t^* m_s(k), \quad d_t(k) \simeq \lambda_t m_t(k) \] (145)
This result is also easily seen in the language of EFT, wherein the full transition matrix must include the weak amplitude to lowest order accompanied by rescattering in both incoming and outgoing channels to all orders in the strong interaction. If we represent the lowest order weak contact interaction as
\[ T_{0t\mu}(k) = D_{0t\mu}(\mu)(\vec{\sigma} - \vec{\sigma}_2) \cdot (\vec{k} + \vec{k}') \] (146)
then the full amplitude is given by
\[ T_{t\mu}(k) = \frac{D_{0t\mu}(\mu)}{(1 - C_{0t}(\mu)G_0(k))(1 - C_{0\mu}(\mu)G_1(k))}(\vec{\sigma} - \vec{\sigma}_2) \cdot (\vec{k} + \vec{k}') \] (147)
where we have introduced a lowest order contact term \( C_{0\mu} \) which describes the \( ^1P_1 \)-wave nn interaction. Since the phase of the combination \( 1 - C_{0t}(\mu)G_0(k) \) is simply the negative of the strong interaction phase the unitarity stricture is clear, and we can define the physical transition amplitude \( A_{t\mu} \) via
\[ \frac{D_{0t\mu}(\mu)}{(1 - C_{0t}(\mu)G_0(k))(1 - C_{0\mu}(\mu)G_1(k))} \equiv \frac{A_{t\mu}}{(1 + ik\alpha_t)(1 + ik^3\alpha_p)} \] (148)
Making the identification \( \lambda_t = -\frac{M}{4\pi} A_{t\mu} \) and noting that
\[ \frac{1}{1 + ik\alpha_t} = \cos \delta_t(k)e^{i\delta_t(k)} \]
then $\lambda$ is seen to be identical to the R-matrix element defined by Miller and Driscoll [63].

Now that we have developed a fully unitary transition amplitude we can calculate observables. For simplicity we begin with $nn$ scattering. In this case the Pauli principle demands that the initial state must be purely $^{1}S_0$ at low energy. One can imagine longitudinally polarizing one of the neutrons and measuring the total scattering cross section on an unpolarized target. Since $\vec{\sigma} \cdot \vec{k}$ is odd under parity, the cross section can depend on the helicity only if parity is violated. Using trace techniques the helicity correlated cross section can easily be found. Since the initial state must be in a spin singlet we have

$$\sigma_\pm = \int d\Omega \frac{1}{2} \text{Tr} M(\vec{k}', \vec{k}) \frac{1}{2} (1 + \vec{\sigma}_2 \cdot \vec{k}) \frac{1}{4} (1 - \vec{\sigma}_1 \cdot \vec{k}) M^\dagger(\vec{k}', \vec{k})$$

$$= |m_s(k)|^2 \pm 4k \text{Re} m_s^*(k) d_{nn}^{m_0}(k) + O(d_s^2)$$ (149)

Defining the asymmetry via the sum and difference of such helicity cross sections and neglecting the tiny P-wave scattering, we have then

$$A = \frac{\sigma_+ - \sigma_-}{\sigma_+ + \sigma_-} = \frac{8k \text{Re} m_s^*(k) d_{nn}^{m_0}(k)}{2|m_s(k)|^2} = 4k \lambda_{nn}$$ (150)

Thus the helicity correlated $nn$-scattering asymmetry provides a direct measure of the parity-violating parameter $\lambda_{nn}$. Note that in the theoretical evaluation of the asymmetry, since the total cross section is involved some investigators opt to utilize the optical theorem via [64, 65]

$$A = \frac{4k \text{Im} d_{nn}^{m_0}(k)}{\text{Im} m_s(k)}$$ (151)

which, using our unitarized forms, is completely equivalent to Eq. (150).

Of course, $nn$-scattering is purely a gedanken experiment and we have discussed it only as a warmup to the real problem—$pp$ scattering, which introduces the complications associated with the Coulomb interaction. In spite of this complication, the calculation proceeds quite in parallel to the discussion above with obvious modifications. Specifically, as shown in [66] the unitarized the scattering amplitude now has the form

$$m_s(k) = -\frac{M}{4\pi} \frac{C_0 C_0^2(\eta_+(k)) \exp 2i\sigma_0}{1 - C_0 G_{CC}(k)}$$ (152)

where $\eta_+(k) = M \alpha/2k$ and

$$C^2(x) = \frac{2\pi x}{e^{2\pi x} - 1}$$ (153)

is the usual Sommerfeld factor and $\sigma_0 = \text{arg} \Gamma(\ell + 1 + i\eta(k))$ is the Coulomb phase shift. Of course, the free Green’s function $G_0(k)$ has also been replaced by its Coulomb analog

$$G_{CC}(k) = \int \frac{d^3s}{(2\pi)^3} \frac{C^2(\eta_+(k))}{\frac{k^2}{M} - \frac{s^2}{M} + i\epsilon}$$ (154)
Remarkably this integral can be performed analytically and the result is

\[ G_C(k) = -\frac{M}{4\pi} \left[ \mu + M\alpha \left( H(i\eta_+(k)) - \log \frac{\mu}{\pi M\alpha} - \zeta \right) \right] \]  

(155)

Here \( \zeta \) is defined in terms of the Euler constant \( \gamma_E \) via \( \zeta = \frac{2\pi}{\gamma_E} - \gamma_E \) and

\[ H(x) = \psi(x) + \frac{1}{2x} - \log x \]  

(156)

The resultant scattering amplitude has the form

\[ m_s(k) = \frac{C_\eta^2(\eta_+(k))e^{2i\sigma_0}}{\frac{4\pi}{M\alpha} - \mu - M\alpha \left[ H(i\eta_+(k)) - \log \frac{\mu}{\pi M\alpha} - \zeta \right]} \]  

\[ = \frac{C_\eta^2(\eta_+(k))e^{2i\sigma_0}}{-\frac{1}{a_{0s}} - M\alpha \left[ h(\eta_+(k)) - \log \frac{\mu}{\pi M\alpha} - \zeta \right] - ikC_\eta^2(\eta_+(k))} \]  

(157)

where we have defined

\[ -\frac{1}{a_{0s}} = -\frac{4\pi}{M\alpha} - \mu, \quad \text{and} \quad h(\eta_+(k)) = \text{Re}H(i\eta_+(k)) \]  

(158)

The experimental scattering length \( a_{Cs} \) in the presence of the Coulomb interaction is defined via

\[ -\frac{1}{a_{Cs}} = -\frac{1}{a_{0s}} + M\alpha \left( \log \frac{\mu}{\pi M\alpha} - \zeta \right) \]  

(159)

in which case the scattering amplitude takes its traditional form

\[ m_s(k) = \frac{C_\eta^2(\eta_+(k))e^{2i\sigma_0}}{-\frac{1}{a_{Cs}} - M\alpha H(i\eta_+(k))} \]  

(160)

Of course, this means that the Coulomb-corrected scattering length is different from its non-Coulomb analog, and comparison of the experimental pp scattering length—\( a_{pp} = -7.82 \) fm—with its nn analog—\( a_{nn} = -18.8 \) fm—is roughly consistent with Eq. (159) if a reasonable cutoff, say \( \mu \sim 1\text{GeV} \) is chosen. Having unitarized the strong scattering amplitude, we can proceed similarly for its parity-violating analog. Again summing the rescattering bubbles and neglecting the small p-wave scattering, we find for the unitarized weak amplitude

\[ T_{0SP} = \frac{D_{0sp}(\mu)C_\eta^2(\eta_+(k))e^{i(\sigma_0+\sigma_1)}}{1 - C_{0s}(\mu)G_C(k)} = \frac{A_{Csp}C_\eta^2(\eta_+(k))e^{i(\sigma_0+\sigma_1)}}{-\frac{1}{a_{Cs}} - M\alpha H(i\eta_+(k))} \]  

(161)

Here again, the Driscoll-Miller procedure identifies \( A_{Csp} = \lambda_s^{pp} \) via the R-matrix. Having obtained fully unitarized forms, we can then proceed to evaluate the helicity correlated cross sections, finding as before

\[ A_h = \frac{\sigma_+ - \sigma_-}{\sigma_+ + \sigma_-} = \frac{8k\text{Re}m_s^*(k)d_{pp}^{pp}(k)}{2|m_s(k)|^2} \simeq 4k\lambda_s^{pp} \]  

(162)
Note here that the superscript \( pp \) has been added, in order account for the feature that in the presence of Coulomb interactions the parity mixing parameter \( \lambda_s \) which is appropriate for neutral scattering is modified, in much the same way as the scattering length in the \( pp \) channel is modified (cf. Eq. (159)). On the experimental side such asymmetries have been measured both at low energy (13.6 and 45 MeV) as well as at higher energy (221 and 800 MeV) but it is only the low energy results\(^4\)

\[
A_h(13.6 \text{ MeV}) = -(0.93 \pm 0.20 \pm 0.05) \times 10^{-7} \quad \text{[67]}
\]
\[
A_h(45 \text{ MeV}) = -(1.57 \pm 0.23) \times 10^{-7} \quad \text{[68]} \quad (164)
\]

which are appropriate for our analysis. Note that one consistency check on these results is that if the simple discussion given above is correct the two numbers should be approximately related by the kinematic factor\(^5\)

\[
A_h(45 \text{ MeV})/A_h(13.6 \text{ MeV}) \simeq k_1/k_2 = 1.8 \quad (165)
\]

and the quoted numbers are quite consistent with this requirement. We can then extract the experimental number for the singlet mixing parameter as

\[
\lambda_{spp} = \frac{A_h}{4k} = -(4.0 \pm 0.8) \times 10^{-8} \text{ fm} \quad (166)
\]

In principle one could extract the triplet parameters by a careful nd scattering measurement. However, extraction of the needed np amplitude involves a detailed theoretical analysis which has yet not been performed. Thus instead we discuss the case of electromagnetic interactions and consider \( np \leftrightarrow d\gamma \).

### 7 Parity Violating Electromagnetic Interaction: \( np \leftrightarrow d\gamma \)

A second important low energy probe of hadronic parity violation can be found within the electromagnetic transition \( np \leftrightarrow d\gamma \). Here the np scattering states include both spin-singlet and -triplet components and we must include a bound state—the deuteron. Analysis of the corresponding parity-conserving situation has been given previously, so we concentrate here on the parity violating situation. In this case, the mixing of the scattering states has already been given in Eq. (160) while for the deuteron the result can be found from demanding orthogonality with the \( ^3S_1 \) scattering state—

\[
\psi_d(r) = \left(1 + \rho(t)\hat{\sigma}_p + \vec{\sigma}_n \right) \cdot -i\vec{\nabla} + \lambda_t(\hat{\sigma}_p - \hat{\sigma}_n) \cdot -i\vec{\nabla} \right) \frac{\gamma-\frac{1}{2\pi r} e^{-\gamma r}}{r} \quad (167)
\]

\(^4\)Note that the 13.6 MeV Bonn measurement is fully consistent with the earlier but less precise number

\[
A_h = -(1.7 \pm 0.8) \times 10^{-7} \quad \text{[69]} \quad (163)
\]

determined at LANL.

\(^5\)There is an additional \( k \)-dependence arising from \( \lambda_t \) but this is small.
Having found λₕ via the pp scattering asymmetry, we now need to focus on the determination of the parity-violating triplet parameters ρₜ, λₜ. In order to do so, we must evaluate new matrix elements. There are in general two types of PV E1 matrix elements, which we can write as

\[ \text{Amp} = \left( H_{E1}^{1P} \vec{\sigma}_p - \vec{\sigma}_n \right) \chi_t + S_{E1}^{1P} \left( \vec{\sigma}_p + \vec{\sigma}_n \right) \chi_t \right) \cdot e_γ \]  

(168)

and there exist two separate contributions to each of these amplitudes, depending upon whether the parity mixing occurs in the initial or final state. We begin with the matrix element which connects the \(^1P_1\) admixture of the deuteron to the \(^1S_0\) scattering state.

\[
H_{E1}^{1P} = \frac{e_{S0} \lambda_1}{2} \frac{1}{3} \int d^3 r \psi_S^{1−}(r)^* \vec{\nabla} \psi_d(r)
\]

\[
= \frac{e_{S0} 4\pi \lambda_1}{6} e^{i\delta_t} \int_0^\infty dr r \frac{1}{kr} (\sin kr \cos \delta_s + \cos kr \sin \delta_s) \vec{\nabla} \sqrt{\frac{\gamma_1}{2\pi r}} e^{-\gamma r}
\]

\[
= \frac{e_{S0} \sqrt{8\pi \gamma \lambda_2} e^{i\delta_t}}{6} \int_0^\infty dr (\sin kr \cos \delta_s + \cos kr \sin \delta_s) e^{-\gamma r}
\]

\[
\times (1 - \frac{\gamma d}{d\gamma}) \int_0^\infty dr (\sin kr \cos \delta_s + \cos kr \sin \delta_s) e^{-\gamma r}
\]

\[
= \frac{e_{S0} \lambda_t \sqrt{8\pi \gamma \lambda_2} e^{-i\delta_s}}{6} \int_0^\infty dr \frac{1}{k^2 + q^2 a^2} \left[ \frac{k^2 + 3\gamma^2}{(k^2 + \gamma^2)^2} \right]
\]

(169)

Equivalently we can use EFT methods using the diagrams of Figure 4. We have from Figure 4a

\[
H_{E1}^{a} \left( 1P - 1S \right) = \frac{e_{S0} \lambda_1}{2} \frac{1}{3} \int \frac{d^3 q}{(2\pi)^3} \psi_S^{(0)}(q)^* \vec{\nabla} \vec{q} \cdot (\vec{q} \psi_d(q))
\]

\[
= \frac{e_{S0} \lambda_1 \sqrt{8\pi \gamma \lambda_2}}{6} \int \frac{d^3 q}{(2\pi)^3} \psi_S^{(0)}(q)^* \vec{\nabla} \vec{q} \cdot (\vec{q} \psi_d(q))
\]

(170)

while from the bubble sum in Figure 4b+c we find

\[
H_{E1}^{b+c} \left( 1P - 1S \right) = \frac{e_{S0} \lambda_1}{2} \frac{1}{3} \left( \frac{C_{0s}}{1 - C_{0s} G_0(k)} \right) \int \frac{d^3 q}{(2\pi)^3} G_0(i\vec{q}) \vec{\nabla} \vec{q} \cdot (\vec{q} \psi_d(q))
\]

\[
= \frac{e_{S0} M \sqrt{8\pi \gamma \lambda_2}}{6} \left( \frac{C_{0s}}{1 - C_{0s} G_0(k)} \right) \times \int \frac{d^3 q}{(2\pi)^3} \frac{q^2 + 3\gamma^2}{(q^2 + \gamma^2)^2 (\frac{k^2}{M^2} - \frac{q^2}{M^2} + i\epsilon)}
\]

(171)

Here the integral may be evaluated via

\[
\int \frac{d^3 q}{(2\pi)^3} \frac{q^2 + 3\gamma^2}{(q^2 + \gamma^2)^2 (\frac{k^2}{M^2} - \frac{q^2}{M^2} + i\epsilon)} = \left( 1 - 2\gamma^2 \frac{d}{d\gamma^2} \right) \left( \frac{1}{(k^2 + \gamma^2)^2} (G_0(k) - G_0(i\gamma)) \right)
\]
Green's function representation of the scattering amplitude as wavefunction mixed into the $1^1$ and leads to an $E1$ amplitude connecting the deuteron wavefunction with the $3^3$ as found using coordinate space methods.

Summing the two results we find

$$H_{E1}(^1P - ^1S) = \frac{e\omega\sqrt{8\pi\gamma}\lambda_t}{2} \frac{1}{3(k^2 + \gamma^2)^2} \left( k^2 + 3\gamma^2 - a_s \frac{(2\gamma - ik)(\gamma + ik)^2}{1 + ika_s} \right)$$

and leads to an $E1$ amplitude

$$H_{E1}(^3P - ^3S) = \frac{e\omega\lambda^{np}m_s^*(k)}{2} \int d^3r \psi_d(r)\vec{r} \cdot \frac{e^{-ikr}}{r} \psi^*_0(kr)$$

The matrix element $H_{E1}$ also receives contributions from the $E1$ amplitude connecting the deuteron wavefunction with the $^3P$ mixture of the final state wavefunction mixed into the $^1S_0$. This admixture can be read off from the Green's function representation of the scattering amplitude as

$$\delta_{3P}\psi_{3S} = -im_s(k)(\vec{\sigma}_p - \vec{\sigma}_n) \cdot \frac{e^{-ikr}}{r}$$

and leads to an $E1$ amplitude

$$H_{E1}(^3P - ^3S) = \frac{e\omega\lambda^{np}m_s^*(k)}{2} \left( C_{0s} \right) \left( 1 - \frac{C_{0s}G_0(k)}{C_{0s}G_0(k)} \right)$$

Equivalently we can use EFT techniques. In this case there is no analog of Figure 4a. For the remaining diagrams, however, we find

$$H_{E1}^{\lambda_{c}P}(^3P - ^3S) = \frac{e\omega\lambda^{np}}{6} \left( \frac{C_{0s}}{G_0(k)} \right) \left( 1 + \frac{C_{0s}G_0(k)}{G_0(k)} \right)$$

i.e.,

$$H_{E1}(^3P - ^3S) = \frac{e\omega\lambda^{np}\sqrt{8\pi\gamma} e^{-it\lambda^{-1}ka_s}}{6(k^2 + \gamma^2)^2 \sqrt{1 + k^2a_s^2}} a_s [\gamma^2 + 3k^2] \gamma - 2ik^3]$$
as found in coordinate space.

The full matrix element is then found by combining the singlet and triplet mixing contributions—

\[ H_{E1} = H_{E1}(3P - 3S) + H_{E1}(1P - 1S) \]

\[ = \frac{e s_0 \sqrt{8 \pi \gamma e^{-i \delta_s}}}{6 \sqrt{1 + k^2 a_s^2(\gamma^2 + \gamma^2)^2}} \times [\lambda_t(\gamma^2 + 3\gamma^2 - 2a_s\gamma^3) + \lambda_{np}^p \gamma a_s((\gamma^2 + 3k^2)\gamma - 2ik^3)] \] (178)

In the case of the PV E1 matrix element \( S_{E1} \) the calculation appears to be nearly identical, except for the feature that now the spin triplet final state is involved, so that the calculation already performed in the case of \( H_{E1} \) can be taken over directly provided that we make the substitutions \( \lambda_{np}^p, \lambda_t \rightarrow \rho_t, a_s \rightarrow a_t \). The result is found then to be

\[ S_{E1} = \frac{e s_0 \sqrt{8 \pi \gamma e^{-i \tan^{-1} ka}} \rho_t}{6 \sqrt{1 + k^2 a_t^2(\gamma^2 + \gamma^2)^2}} \times [(\gamma^2 + 3\gamma^2 - 2a_t\gamma^3) + a_t(\gamma(\gamma^2 + 3k^2) - 2ik^3)] \] (179)

At the level of approximation we are working we can identify \( a_t \) with \( 1/\gamma \) so that Eq. (179) becomes

\[ S_{E1} = \frac{e s_0 \sqrt{8 \pi \gamma e^{-i \tan^{-1} \frac{k}{\gamma}} \rho_t}}{3 \sqrt{1 + k^2(\gamma^2 + \gamma^2)^2}} \] (180)

Now consider how to detect these PV amplitudes. The parity violating electric dipole amplitude \( H_{E1} \) can be measured by looking at the circular polarization which results from unpolarized radiative capture at threshold or by the asymmetry resulting from the scattering of polarized photons in photodisintegration. At threshold, we have for photons of positive/negative helicity

\[ \text{Amp}_\pm = (\pm G_{M1V} + H_{E1}) \epsilon_\gamma \cdot \chi_\gamma^s(\vec{\sigma}_p - \vec{\sigma}_n)\chi_t + S_{E1} \epsilon_\gamma \cdot \chi_0^t(\vec{\sigma}_p + \vec{\sigma}_n)\chi_t \] (181)

and the corresponding cross sections are found to be

\[ \sigma_\pm(np \rightarrow d\gamma) = \frac{s_0}{2\pi |\vec{e}_{rel}|} |\mp G_{M1V} + H_{E1}|^2 + O(S_{E1}^2) \] (182)

Thus the spin-conserving E1 amplitude \( S_{E1} \) does not interfere with the leading M1 and the circular polarization is given by

\[ P_\gamma = \frac{\sigma_+ - \sigma_-}{\sigma_+ + \sigma_-} = \frac{2H_{E1}}{G_{M1V}} = -\frac{4M}{3\mu V(1 - \gamma a_s)(\gamma^2 + \gamma^2)} \left[ \lambda_t(\gamma^2 + 3\gamma^2 - 2a_s\gamma^3) + \lambda_{np}^p \gamma a_s(\gamma^2 + 3k^2) \right] \] (183)

A bit of thought makes it clear that this is also the asymmetry parameter between right- and left-handed circularly polarized cross sections in the photodisintegration reaction \( \gamma d \rightarrow np \), and so we have the usual identity between polarization and asymmetry which is guaranteed by time reversal invariance

\[ P_\gamma(np \rightarrow d\gamma) = A_\gamma(\vec{\gamma}d \rightarrow np) \]
In order to gain sensitivity to the matrix element $S_{E1}$ one must use polarized neutrons. In this case the appropriate trace is found to be

$$\text{Tr} \frac{1}{4} (3 + \vec{\sigma}_1 \cdot \vec{\sigma}_2) \text{Tr} \frac{1}{2} (1 + \sigma_n \cdot \hat{n}) = 4|G_{M1V}|^2 + 8 \text{Re} G^*_{M1V} S_{E1} \hat{n} \cdot \hat{s}_\gamma$$  \hspace{0.3cm} (184)

In this case $H_{E1}$ does not interfere with $G_{M1V}$ and the corresponding front-back photon asymmetry is

$$A_\gamma = \frac{2 \text{Re} G^*_{M1V} S_{E1}}{|G_{M1V}|^2} = -\frac{8 M \rho_t}{3 \mu_V (1 - \gamma a_s)} \left( \frac{\gamma^2 + 2 k^2}{\gamma^2 + k^2} \right)$$  \hspace{0.3cm} (185)

In principle then precise experiments measuring the circular polarization and photon asymmetry in thermal neutron capture on protons can produce the remaining two low energy parity violating parameters $\lambda_{np}$ and $\rho_t$ which we seek. At the present time only upper limits exist, however. In the case of the circular polarization we have the number from a Gatchina measurement

$$P_\gamma = (1.8 \pm 1.8) \times 10^{-7}$$  \hspace{0.3cm} (186)

while in the case of the asymmetry we have

$$A_\gamma = (-1.5 \pm 4.7) \times 10^{-8}$$  \hspace{0.3cm} (187)

from a Grenoble experiment. This situation should soon change, as a new high precision asymmetry measurement at LANL is being run which seeks to improve the previous precision by an order of magnitude.

Appendix

Of course, as we move above threshold we must also include the parity-violating M1 matrix elements, which interfere with the leading E1 amplitude and are of two types. The first is the M1 amplitude which connects the $^1P_1$ admixture of the deuteron with the $^3P$ np scattering state as well as the M1 amplitude connecting the $^1S_0$ admixture of the final $^3P$ scattering state with the deuteron ground state. For the former we have

$$\text{Amp} = J^a_{M1} \psi_t^\dagger (\vec{\sigma}_1 - \vec{\sigma}_2) \cdot \hat{e}_\gamma \times \hat{s}_\gamma (\vec{\sigma}_1 - \vec{\sigma}_2) \cdot \vec{k} \chi_t$$  \hspace{0.3cm} (188)

where

$$J^a_{M1} = \frac{e s_0 \mu_V \lambda_t}{4 M} \frac{\lambda_t}{k^2} \int d^3 r e^{-i \vec{k} \cdot \vec{r}} \nabla \psi_d(r) = \frac{e s_0 \mu_V \sqrt{8 \pi \gamma}}{4 M} \frac{\lambda_t}{(k^2 + \gamma^2)}$$  \hspace{0.3cm} (189)

while for the latter we find

$$\text{Amp} = J^b_{M1} \psi_t^\dagger (\vec{\sigma}_1 - \vec{\sigma}_2) \cdot \hat{e}_\gamma \times \hat{s}_\gamma \chi_t$$  \hspace{0.3cm} (190)

For simplicity here we include only the dominant isovector M1 amplitude. A complete discussion should also include the corresponding isoscalar M1 transition.
where

\[
J_{M1}^b = \frac{e_s \mu \nu}{4M} \lambda_s^a m_s^a(k) \int d^3r \frac{1}{r} e^{-i k r} \psi_d(r) = -\frac{e_s \mu \nu}{4M} \frac{\lambda_s^a a_s \sqrt{8 \pi} \gamma}{(1 - i k a_t)(\gamma + i k)} \tag{191}
\]

A second category of PV M1 amplitudes involves that which connects the \(3P_1\) piece of the deuteron wavefunction with the \(1P_1\) or \(3P_1\) np scattering states as well as the M1 amplitude connecting the \(3S_1\) or \(1S_0\) admixture of the final \(3P\) scattering state with the deuteron ground state. For the former we have

\[
K_{M1}^a \chi_1^1[(\bar{\sigma}_1 - \bar{\sigma}_2) \cdot \hat{\epsilon}_\gamma \times \hat{s}_\gamma (\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \bar{k} \chi_t \tag{192}
\]

\[
L_{M1}^a \chi_1^1[(\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \hat{\epsilon}_\gamma \times \hat{s}_\gamma (\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \bar{k} \chi_t \tag{193}
\]

while for the latter we have

\[
Amp = K_{M1}^b \chi_1^1[(\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \bar{k}(\bar{\sigma}_1 - \bar{\sigma}_2) \cdot \hat{\epsilon}_\gamma \times \hat{s}_\gamma \chi_t \tag{196}
\]

\[
Amp = L_{M1}^b \chi_1^1[(\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \bar{k}(\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \hat{\epsilon}_\gamma \times \hat{s}_\gamma \chi_t \tag{197}
\]

where

\[
K_{M1}^b = \frac{e_s \mu \nu}{4M} \rho_t m_t^a(k) \int d^3r \frac{1}{r} e^{-i k r} \psi_d(r) = -\frac{e_s \mu \nu}{4M} \frac{\rho_t a_t \sqrt{8 \pi} \gamma}{(1 - i k a_t)(\gamma + i k)} \tag{198}
\]

\[
L_{M1}^b = \frac{e_s \mu \nu}{4M} \rho_t m_t^a(k) \int d^3r \frac{1}{r} e^{-i k r} \psi_d(r) = -\frac{e_s \mu \nu}{4M} \frac{\rho_t a_t \sqrt{8 \pi} \gamma}{(1 - i k a_t)(\gamma + i k)} \tag{199}
\]

To this order we can use \(a_t \approx 1/\gamma\), so that

\[
K_{M1}^b = -\frac{e_s \mu \nu}{4M} \frac{\rho_t \sqrt{8 \pi} \gamma}{k^2 + \gamma^2} \tag{200}
\]

\[
L_{M1}^b = -\frac{e_s \mu \nu}{4M} \frac{\rho_t \sqrt{8 \pi} \gamma}{k^2 + \gamma^2} \tag{201}
\]

We see then that this piece of the M1 amplitude has the form

\[
Amp = 2i (\hat{\epsilon}_\gamma \times \hat{s}_\gamma) \times \bar{k} \cdot \chi_1^1[K_{M1}^a(\bar{\sigma}_1 - \bar{\sigma}_2) + L_{M1}^a(\bar{\sigma}_1 + \bar{\sigma}_2)] \chi_t \tag{202}
\]

The relevant traces here are

\[
\text{Tr}_{\frac{1}{4}}[(3 + \bar{\sigma}_1 \cdot \bar{\sigma}_2)(J_{M1}^b(\bar{\sigma}_1 - \bar{\sigma}_2) \cdot \hat{\epsilon}_\gamma \times \hat{s}_\gamma (\bar{\sigma}_1 - \bar{\sigma}_2) \cdot \bar{k} = -J_{M1}^b(\bar{\sigma}_1 - \bar{\sigma}_2) \cdot \bar{k}(\bar{\sigma}_1 - \bar{\sigma}_2) \cdot \hat{\epsilon}_\gamma \times \hat{s}_\gamma ] \frac{1}{2}(1 + \bar{\sigma}_2 \cdot \hat{\alpha}) \tag{203}
\]

\[
= 2(J_{M1}^a + J_{M1}^b) \hat{\epsilon}_\gamma \times \hat{s}_\gamma \cdot \bar{k} + 2i(J_{M1}^a - J_{M1}^b) \hat{\alpha} \cdot (\hat{\epsilon}_\gamma \times \hat{s}_\gamma) \times \bar{k} \tag{204}
\]
having sensitivity to the couplings
understand the basic physics of this transformation and by which to make
in form. However, it is very useful to have an analytic form by which to un-
even after this connection has been completed, the results will be numerical
the work is underway, but it will be some time until this process is completed.
and should involve the latest and best NN wavefunctions such as Argonne V18.
Having a form of the weak parity-violating potential

\[ \frac{1}{4} \left( 3 + \bar{\sigma}_1 \cdot \bar{\sigma}_2 \right) \left( K_{M1}^a (\bar{\sigma}_1 - \bar{\sigma}_2) \cdot \hat{\epsilon}_\gamma \times \hat{s}_\gamma (\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \hat{k} \right. \\
+ \left. K_{M1}^b (\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \hat{k} (\bar{\sigma}_1 - \bar{\sigma}_2) \cdot \hat{\epsilon}_\gamma \times \hat{s}_\gamma \right) \frac{1}{2} (1 + \bar{\sigma}_2 \cdot \hat{n}) \\
= 2 (L_{M1}^a + \bar{L}_{M1}^b) \epsilon_\gamma \times \hat{s}_\gamma \cdot \hat{k} + 2i (L_{M1}^a - \bar{L}_{M1}^b) \hat{n} \cdot (\hat{\epsilon}_\gamma \times \hat{s}_\gamma) \times \hat{k} \\
= 4i L_{M1}^a \hat{n} \cdot (\hat{\epsilon}_\gamma \times \hat{s}_\gamma) \times \hat{k} \]  

\[ \frac{1}{4} \left( 3 + \bar{\sigma}_1 \cdot \bar{\sigma}_2 \right) \left( L_{M1}^a (\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \hat{\epsilon}_\gamma \times \hat{s}_\gamma (\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \hat{k} \right. \\
+ \left. L_{M1}^b (\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \hat{k} (\bar{\sigma}_1 + \bar{\sigma}_2) \cdot \hat{\epsilon}_\gamma \times \hat{s}_\gamma \right) \frac{1}{2} (1 + \bar{\sigma}_2 \cdot \hat{n}) \\
= 2 (L_{M1}^a + \bar{L}_{M1}^b) \epsilon_\gamma \times \hat{s}_\gamma \cdot \hat{k} + 2i (L_{M1}^a - \bar{L}_{M1}^b) \hat{n} \cdot (\hat{\epsilon}_\gamma \times \hat{s}_\gamma) \times \hat{k} \\
= 4i L_{M1}^a \hat{n} \cdot (\hat{\epsilon}_\gamma \times \hat{s}_\gamma) \times \hat{k} \]  

and the corresponding contribution to the cross section for photodisintegration
by photons of differing helicity is

\[ \sigma_\pm = \frac{M^2 k^3}{12 \pi (\gamma^2 + k^2)} \left| G_{E1} \right|^2 \pm \frac{8}{3} \text{Re} G_{E1}^* \left( J_{M1}^a + j_{M1}^b \right) \right] \\
= \frac{8 \pi \gamma k^3 \alpha}{3(k^2 + \gamma^2)^3} \left[ 16 \pi \gamma k^3 \alpha \mu \nu \frac{1}{(k^2 + \gamma^2)} \left( \lambda_t - \lambda_{\mu p} \alpha_s \gamma + k^2 a_s \right) \right] \]  

Note that there is only sensitivity to the couplings \( J_{M1} \) here. In order to
have sensitivity to the couplings \( K_{M1}, L_{M1} \) we must look at the E1 contribution
to the cross section for the radiative capture of polarized neutrons—

\[ \frac{d\sigma}{d\Omega_{\hat{s}_\gamma}} = \frac{\gamma^2 + k^2}{32 \pi^2 |V_{\text{re}}|^4 M} \left( 3 \left| G_{E1} \right|^2 (k^2 - (\hat{k} \cdot \hat{s}_\gamma)^2) + 8 \text{Re} G_{E1}^* (K_{M1}^a + L_{M1}^a) \hat{s}_\gamma \cdot \hat{k} \hat{s}_\gamma \times \hat{k} \cdot \hat{n} \right) \right] \\
= \frac{3 \alpha \gamma - k^2 - (\hat{k} \cdot \hat{s}_\gamma)^2}{M^4 |V_{\text{re}}|^4} + \frac{2 \alpha \gamma (\mu \nu + \mu \tilde{\nu}) \rho_{\tilde{\nu}}}{M^4 |V_{\text{re}}|^4} \hat{s}_\gamma \cdot \hat{k} \hat{s}_\gamma \times \hat{k} \cdot \hat{n} \]  

Careful analysis of above threshold experiments should include these NLO
corrections to the analysis.

8 Connecting with Theory

Having a form of the weak parity-violating potential \( V^{PNC} \) it is, of course,
essential to complete the process by connecting with the S-matrix—i.e., expressing the phenomenological parameters \( \lambda_t, \rho_t \) defined in Eq. [13] in terms of the
fundamental ones—\( C_t, \tilde{C}_t \) defined in Eq. [14]. This is a major undertaking
and should involve the latest and best NN wavefunctions such as Argonne V18.
The work is underway, but it will be some time until this process is completed.
Even after this connection has been completed, the results will be numerical
in form. However, it is very useful to have an analytic form by which to under-
stand the basic physics of this transformation and by which to make simple

38
numerical estimates. For this purpose we shall employ simple phenomenological NN wavefunctions, as described below.

Examination of the scattering matrix Eq. 130 reveals that the parameters $\lambda_{s,t}$ are associated with the (short-distance) component while $\rho_t$ contains contributions from the both (long-distance) pion exchange as well as short distance effects. In the former case, since the interaction is short ranged we can use this feature in order to simplify the analysis. Thus, we can determine the shift in the deuteron wavefunction associated with parity violation by demanding orthogonality with the $^3S_1$ scattering state, which yields, using the simple asymptotic form of the bound state wavefunction $[42]$, $[43]$

$$\psi_d(r) = \left[1 + \rho_t(\vec{\sigma}_p + \vec{\sigma}_n) \cdot -i\vec{\nabla} + \lambda_t(\vec{\sigma}_p - \vec{\sigma}_n) \cdot -i\vec{\nabla}\right] \sqrt{\frac{\gamma}{2\pi}} e^{-\gamma r} \tag{208}$$

where $\gamma/2M = 2.23$ MeV is the deuteron binding energy. Now the shift generated by $V^{PV}(r)$ is found to be $[42]$, $[43]$

$$\delta \psi_d(r) \simeq \int d^3r' G(\vec{r}, \vec{r}') V^{PV}(\vec{r}') \psi_d(r')$$

$$= \frac{M}{4\pi} \int d^3r' \frac{e^{-\gamma|\vec{r}' - \vec{r}|}}{|\vec{r}' - \vec{r}|} V^{PV}(\vec{r}') \psi_d(r')$$

$$\simeq \frac{M}{4\pi} \hat{\nabla} \left(\frac{e^{-\gamma r}}{r}\right) \cdot \int d^3r' V^{PV}(\vec{r}') \psi_d(r') \tag{209}$$

where the last step is permitted by the short range of $V^{PV}(\vec{r}')$. Comparing Eqs. 209 and 208 yields then the identification

$$\sqrt{\frac{\gamma}{2\pi}} \chi_t = i \frac{M}{16\pi} \xi_0 \int d^3r' (\vec{\sigma}_1 - \vec{\sigma}_2) \cdot \vec{r}' V^{PV}(\vec{r}') \psi_d(r') \chi_t \xi_0 \tag{210}$$

where we have included the normalized isospin wavefunction $\xi_0$ since the potential involves $\vec{\sigma}_1, \vec{\sigma}_2$. When operating on such an isosinglet np state the PV potential can be written as

$$V^{PV}(\vec{r}') = \frac{2}{\Lambda^2} \left[(C_1 - 3C_3)(\vec{\sigma}_1 - \vec{\sigma}_2) \cdot (-i\vec{\nabla} f_m(r) + 2f_m(r) \cdot -i\vec{\nabla}) + (\tilde{C}_1 - 3\tilde{C}_3)(\vec{\sigma}_1 \times \vec{\sigma}_2) \cdot \vec{\nabla} f_m(r)\right] \tag{211}$$

where $f_m(r)$ is the Yukawa form

$$f_m(r) = \frac{m^2 e^{-mr}}{4\pi r}$$

defined in Eq. 6. Using the identity

$$(\vec{\sigma}_1 \times \vec{\sigma}_2) \frac{1}{2} (1 + \vec{\sigma}_1 \cdot \vec{\sigma}_2) = i(\vec{\sigma}_1 - \vec{\sigma}_2) \tag{212}$$
Eq. 210 becomes
\[
\sqrt{\frac{\gamma}{2\pi}} \lambda_1 \chi_i \simeq \frac{2M}{16\pi A^3_\chi} \frac{4\pi}{3} (\bar{\sigma}_1 - \bar{\sigma}_2)^2 \chi_i \int_0^\infty drr^3 \times \left[ -2(3C_3 - C_1)f_m(r) \frac{d\psi_d(r)}{dr} + (3\tilde{C}_3 - 3C_3 - \tilde{C}_1 + C_1) \frac{df_m(r)}{dr} \psi_d(r) \right] = \sqrt{\frac{\gamma}{2\pi}} \cdot 4\chi \cdot \frac{1}{12} \frac{2Mm^2}{4\pi A^3_\chi} \left( \frac{2m(6C_3 - 3\tilde{C}_3 - 2C_1 + \tilde{C}_1) + \gamma(15C_3 - 3\tilde{C}_3 - 5C_1 + \tilde{C}_1)}{\gamma + m} \right)
\]

or
\[
\lambda_1 \simeq \frac{Mm^2}{6\pi A^3_\chi} \left( \frac{2m(6C_3 - 3\tilde{C}_3 - 2C_1 + \tilde{C}_1) + \gamma(15C_3 - 3\tilde{C}_3 - 5C_1 + \tilde{C}_1)}{\gamma + m} \right)
\]

In order to determine the singlet parameter \(\lambda^{np}_s\), we must use the \(1S_0\) np-scattering wavefunction instead of the deuteron, but the procedure is similar, yielding \[42,43\]
\[
d^{np}(k)\chi_s = \frac{M}{48\pi} \xi^1 \int d^3r' (\bar{\sigma}_1 - \bar{\sigma}_2) \cdot \bar{r}' V^{PV}(\bar{r}') \psi_{s_0}(r') \chi_s \xi_1
\]

and we can proceed similarly. In this case the potential becomes
\[
V^{PV}(\bar{r}') = \frac{2}{A_\chi} \left[ (C_1 + C_3 + \frac{1}{6} C_5)(\bar{\sigma}_1 - \bar{\sigma}_2) \cdot (-i\vec{\nabla} f_m(r) + 2f_m(r) \cdot -i\vec{\nabla}) + (\tilde{C}_1 + \tilde{C}_3 + \frac{1}{6} \tilde{C}_5)(\bar{\sigma}_1 \times \bar{\sigma}_2) \cdot \vec{\nabla} f_m(r) \right]
\]

and Eq. 215 is found to have the form
\[
d^{np}(k)\chi_s = \frac{2M}{48\pi} \frac{4\pi}{3} (\bar{\sigma}_1 - \bar{\sigma}_2)^2 \chi_s \int_0^\infty drr^3 \left[ 2(C_1 + C_3 + 4C_5)f_m(r) \frac{d\psi_{s_0}(r)}{dr} + (C_1 + \tilde{C}_1 + C_3 + \tilde{C}_3 + 4(C_5 + \tilde{C}_5)) \frac{df_m(r)}{dr} \psi_{s_0}(r) \right] = -12\chi_s \frac{1}{36} \frac{2Mm^2}{4\pi A^3_\chi} e^{i\delta_s} \left[ \frac{1}{(k^2 + m^2)^2} \times \left( \cos \delta_s (4k^2(C_1 + C_3 + 4C_5) + (C_1 + \tilde{C}_1 + C_3 + \tilde{C}_3 + 4(C_5 + \tilde{C}_5))(k^2 + 3m^2)) + \frac{2m}{k} \sin \delta_s ((C_1 + C_3 + 4C_5)(m^2 + 3k^2) + (C_1 + \tilde{C}_1 + C_3 + \tilde{C}_3 + 4(C_5 + \tilde{C}_5)m^2) \right) \right]
\]
which, in the limit as \( k \to 0 \), yields the predicted value for \( \lambda_s^{np} \):

\[
\lambda_s^{np} = - \frac{1}{a_s^{np}} \lim_{k \to 0} d_s^{np}(k) = \frac{M}{6\pi a_s^{np} \Lambda^3} \left[ 3(C_1 + \tilde{C}_1 + C_3 + \tilde{C}_3 + 4(C_5 + \tilde{C}_5)) \right]
\]

Similarly, we may identify \( \rho \)

\[
\rho_{np}(2C_1 + \tilde{C}_1 + 2C_3 + \tilde{C}_3 + 4(2C_5 + \tilde{C}_5)))
\]

In order to evaluate the spin-conserving amplitude \( \rho_t \), we shall assume dominance of the long range pion component. The shift in the deuteron wavefunction is given by

\[
\delta \psi_d(r') = i \int d^3r' G_0(r', r') V_\pi^{PV}(r') \psi_d(r')
\]

\[
= -\frac{M}{4\pi} \xi_0^1 \int d^3r' e^{-\gamma |r' - r|} |r' - r| V_\pi^{PV}(r') \psi_d(r') \chi_t \xi_0
\]

but now with\(^7\)

\[
V_\pi^{PV}(r') = \frac{h_\pi g_{\pi NN}}{\sqrt{2Mm_\pi^2}} \frac{1}{2} (\tau_1 - \tau_2) \cdot (\bar{\sigma}_1 + \bar{\sigma}_2) \cdot -i \nabla f_\pi(r)
\]

Of course, the meson which is exchanged is the pion so the short range assumption which permitted the replacement in Eq. 209 is not valid and we must perform the integration exactly. This process is straightforward but tedious.\(^27\)

Nevertheless, we can get a rough estimate by making a “heavy pion” approximation, whereby we can identify the constant \( \rho_t \) via

\[
\sqrt{\frac{\gamma}{2\pi}} \rho_t \chi_t \approx -i \frac{M}{32\pi} \int d^3r' (\bar{\sigma}_1 + \bar{\sigma}_2) \cdot r' V_\pi^{PV}(r') \psi_d(r') \chi_t \xi_0
\]

which leads to\(^7\)

\[
\sqrt{\frac{\gamma}{2\pi}} \rho_t \chi_t \approx \frac{1}{32\pi} \frac{4\pi}{3} (\bar{\sigma}_1 + \bar{\sigma}_2)^2 \chi_t \left[ \frac{h_\pi g_{\pi NN}}{\sqrt{2}} \right] \int_0^\infty dr r^2 \frac{df_\pi(r)}{dr} \psi_d(r)
\]

\(^7\)Here we have used the identity

\[
\langle \bar{\sigma}_1 \times \bar{\sigma}_2 \rangle = -i (\bar{\sigma}_1 - \bar{\sigma}_2)^2 \left[ 1 + \bar{\sigma}_1 \cdot \bar{\sigma}_2 \right]
\]
We find then the prediction

\[ \rho_t = g_{\pi NN} \left( \gamma + 2m_\pi \right) \frac{h_\pi}{12\sqrt{2}\pi (\gamma + m_\pi)^2} \]  

(225)

At this point it is useful to obtain rough numerical estimates. This can be done by use of the numerical estimates given in Table 2. To make things tractable, we shall use the best values given therein. Since we are after only rough estimates and since the best values assume the DDH relationship—Eq. 8 between the tilde- and non-tilde- quantities, we shall express our results in terms of only the non-tilde numbers. Of course, a future complete evaluation should include the full dependence. Of course, these predictions are only within a model, but they has the advantage of allowing connection with previous theoretical estimates. In this way, we find the predictions

\[
\begin{align*}
\lambda_t &= \left[ -0.092C_3 - 0.014C_1 \right] m_\pi^{-1} \\
\lambda_{snp} &= \left[ -0.087(C_3 + 4C_5) - 0.037C_1 \right] m_\pi^{-1} \\
\lambda_{spp} &= \left[ -0.087(C_3 + C_4 - 2C_5) - 0.037(C_1 + C_2) \right] m_\pi^{-1} \\
\lambda_{ssn} &= \left[ -0.087(C_3 - C_4 - 2C_5) - 0.037(C_1 - C_2) \right] m_\pi^{-1} \\
\rho_t &= 0.346 h_\pi m_\pi^{-1} 
\end{align*}
\]  

(226)

so that, using the relations Eq. 9 and the best values from Table 1 we estimate

\[
\begin{align*}
\lambda_t &= -2.39 \times 10^{-7} m_\pi^{-1} = -3.41 \times 10^{-7} \text{ fm} \\
\lambda_{snp} &= -1.12 \times 10^{-7} m_\pi^{-1} = -1.60 \times 10^{-7} \text{ fm} \\
\lambda_{spp} &= -3.58 \times 10^{-7} m_\pi^{-1} = -5.22 \times 10^{-7} \text{ fm} \\
\lambda_{ssn} &= -2.97 \times 10^{-7} m_\pi^{-1} = -4.33 \times 10^{-7} \text{ fm} \\
\rho_t &= 1.50 \times 10^{-7} m_\pi^{-1} = 2.14 \times 10^{-7} \text{ fm} 
\end{align*}
\]  

(227)

At this point we note, however, that \( \lambda_{spp} \) is an order of magnitude larger than the experimentally determined number, Eq. 166 The problem here is not with the couplings but with an important piece of physics which has thus far been neglected—short distance effects. There are two issues here. One is that the deuteron and NN wavefunctions should be modified at short distances from the simple asymptotic form used up until this point in order to account for finite size effects. The second is the well-known feature of the Jastrow correlations that suppress the nucleon-nucleon wavefunction at short distance.

In order to deal approximately with the short distance properties of the deuteron wavefunction, we modify the exponential form to become constant inside the deuteron radius \( R \) \[ \sqrt{\frac{\gamma}{2\pi}} e^{-\gamma r} \rightarrow N \left\{ \begin{array}{ll} \frac{1}{\sqrt{\pi} e^{-\gamma R}} & r \leq R \\ \frac{1}{\sqrt{\pi} e^{-\gamma R}} & r > R \end{array} \right. \]  

(229)
where

\[ N = \sqrt{\frac{\gamma}{2\pi}} \sqrt{\frac{\exp \gamma R}{\exp(\gamma R)}} \]

is the modified normalization factor and we use \( R = 1.6 \text{ fm} \). For the NN wavefunction we use

\[
\psi_{S_0}(r) = \begin{cases} 
A \frac{\sin \sqrt{p^2 + p_0^2} r}{\sin \frac{p r}{p_0} - \frac{1}{n_s + ip} \frac{e^{ipr}}{r}} & r \leq r_s \\
A \frac{\sin \sqrt{p^2 + p_0^2} r}{\sin \frac{p r}{p_0} - \frac{1}{n_s + ip} \frac{e^{ipr}}{r}} & r > r_s
\end{cases}
\]

(230)

where we choose \( r_s = 2.73 \text{ fm} \) and \( p_0 r_s = 1.5 \). The normalization constant \( A(p) \) is found by requiring continuity of the wavefunction and its first derivative at \( r = r_s \)

\[
A(p) = \frac{\sqrt{p^2 + p_0^2} r_s}{\sin \frac{p r_s}{p_0} - \frac{1}{n_s + ip} \frac{e^{ipr_s}}{r_s}} \sin pr_s - pa_s \cos pr_s
\]

(231)

As to the Jastrow correlations we multiply the wavefunction by the simple phenomenological form \[15\]

\[
\phi(r) = 1 - ce^{-dr^2}, \quad \text{with} \quad c = 0.6, \quad d = 3 \text{ fm}^{-2}
\]

(232)

With these modifications we find the much more reasonable values for the constants \( \lambda_{pp,nn}^{\rho,sp} \) and \( \lambda_t \)

\[
\lambda_{pp}^s = [-0.011(C_3 + C_4 - 2C_5) - 0.004(C_1 + C_2)] m^{-1}_\pi
\]
\[
\lambda_{nn}^s = [-0.011(C_3 - C_4 + 2C_5) - 0.004(C_1 - C_2)] m^{-1}_\pi
\]
\[
\lambda_{sp}^s = [-0.011(C_3 + 4C_5) - 0.004C_1] m^{-1}_\pi
\]
\[
\lambda_t = [-0.019C_3 - 0.0003C_1] m^{-1}_\pi
\]

(233)

Using the best values from Table 2 we find then the benchmark values

\[
\lambda_{pp}^s = -4.2 \times 10^{-8} m^{-1}_\pi = -6.1 \times 10^{-8} \text{ fm}
\]
\[
\lambda_{nn}^s = -3.6 \times 10^{-8} m^{-1}_\pi = -5.3 \times 10^{-8} \text{ fm}
\]
\[
\lambda_{sp}^s = -1.3 \times 10^{-8} m^{-1}_\pi = -1.9 \times 10^{-8} \text{ fm}
\]
\[
\lambda_t = -4.7 \times 10^{-8} m^{-1}_\pi = -6.7 \times 10^{-8} \text{ fm}
\]

(234)

Since \( \rho_t \) is a long distance effect, we use the same value as calculated previously as our benchmark number

\[
\rho_t = 1.50 \times 10^{-7} m^{-1}_\pi = 2.14 \times 10^{-7} \text{ fm}
\]

(235)

Obviously the value of \( \lambda_{pp}^s \) is now in much better agreement with the experimental value Eq. 166. Of course, our rough estimate is no substitute for a reliable state of the art wavefunction evaluation. This has been done recently by Carlson et al. and yields, using the Argonne V18 wavefunctions [75]

\[
\lambda_{pp}^s = [-0.008(C_3 + C_4 - 2C_5) - 0.003(C_1 + C_2)] m^{-1}_\pi
\]

(236)
in reasonable agreement with the value calculated in Eq. 233. Similar efforts should be directed toward evaluation of the remaining parameters using the best modern wavefunctions.

We end our brief discussion here, but clearly this was merely a simplistic model calculation. It is important to complete this process by using the best contemporary nucleon-nucleon wavefunctions with the most general EFT potential developed above, in order to allow the best possible restrictions to be placed on the unknown counterterms.

9 Summary

For nearly fifty years both theorists and experimentalists have been struggling to obtain an understanding of the parity-violating nucleon-nucleon interaction and its manifestations in hadronic parity violation. Despite a great deal of effort on both fronts, at the present time there still exists a great deal of confusion both as to whether the DDH picture is able to explain the data which exists and even if this is the case as to the size of the basic weak couplings. For this reason it has recently been advocated to employ and effective field theory approach to the low energy data, which must be describable in terms of five elementary S-matrix elements. Above we have discussed both connection between these S-matrix elements and observables in the NN system via simple analytic methods based both on a conventional wavefunction approach as well as on effective field theory methods. While the results are only approximate, they are in reasonable agreement with those obtained via precision state of the art nonrelativistic potential calculations and serve we hope to aid in the understanding of the basic physics of the parity-violating NN sector. In this way it is hoped that the round of experiments which is currently underway can be used to produce a reliable set of weak couplings, which can in turn be used both in order to connect with more fundamental theory such as QCD as well as to provide a solid basis for calculations wherein such hadronic parity violation is acting.

[35] Note that we are using here the standard convention in nuclear physics wherein the scattering length associated with a weak attractive potential is negative. It is common in particle physics to define the scattering length as the negative of that given here so that a weak attractive potential is associated with a positive scattering length.
