A B S T R A C T

A 78-year-old woman presented to the Emergency Department with a tree branch through the orbit. Her condition was rated 15/15 on the Glasgow coma scale. Computed tomography showed that the distal extremity of the branch was located between the intracavernous segment of the internal carotid artery and the temporal lobe. The foreign body pushed aside without penetrating the medial rectus, the optic nerve, the internal carotid artery, and the temporal lobe. No intracranial bleeding or pneumenccephaly was observed. The chirurgical option was confirmed and the patient transferred for extraction of the foreign body by traction in the axis.

Introduction

The management of a transorbital penetrating trauma can appear to be challenging. We present the case of a woman with a tree branch through the orbit into the skull. This type of trauma is rarely lethal and the prognosis mainly functional.

Case report

A 78-year-old woman accidentally slipped while going down the exterior stairs and fell head first into a hedge. She was admitted to the Emergency Department with a tree branch entering through the orbit (Fig. 1). She presented with left eye ophthalmoplegia, nausea, and average pain. Her condition was

rated 15/15 on the Glasgow coma scale. The ocular globe had preserved tonicity.

Computed tomography (Fig. 2) showed a $7 \times 0.8$ cm foreign body located in the medial part of the orbit passing through the superior orbital fissure. The distal extremity of the branch was located between the intracavernous segment of the internal carotid artery and the temporal lobe. Due to the close contact between the carotid artery and the foreign body, angiography was performed after discussion with the neurosurgeon in order more precisely identify the suspected contact between the carotid artery and the foreign body.

The foreign body seemed to be wrapped up in the intracavernous part of the internal carotid artery. Moreover, the foreign body had close contact with but pushed aside without damaging a number of important structures: the medial rectus, the optic nerve, and the temporal lobe. No intracranial bleeding, pneumencephaly, or bone damage was observed.

The patient received tetanus vaccination, intravenous antibiotics, analgesics, and antiemetics. After discussion between the neurosurgical team and the ophthalmologists, careful extraction was decided on because of the close contact with the carotid artery. No immediate complications or bleeding were observed immediately. However, the patient has vision loss, total ptosis, loss of corneal sensitivity, and total ophthalmoplegia of the left eye.

**Discussion**

When caused by a low velocity trauma, such as in this case, the prognosis of a transorbital penetrating trauma is rarely lethal [1] and most often functional [2]. Prognosis mainly depends on the possible infectious complications and existing vascular lesions during the penetrating trauma and/or extraction [3]. The most frequent site of foreign body penetration of the orbit is through the orbital roof. Transorbital penetrating trauma caused by a fall from a person’s own height occurs predominantly in the male and pediatric populations [1]. A wide

range of treatment options are possible, from simple extraction to a neurochirurgical approach, but depend on the lesions observed and always require antibiotic treatment [4,5].

Patient Consent

The patient provided consent to the publication of all the material referenced here.
