(Dated: November 4, 2014)

The frequency spectra of the entropy and kinetic energy along with the power spectrum of the thermal flux are computed from direct numerical simulations for turbulent Rayleigh-Bénard convection with uniform rotation about a vertical axis in low-Prandtl-number fluids (Pr < 0.6). Simulations are done for convective Rossby numbers Ro ≥ 0.2. The temporal fluctuations of these global quantities show two scaling regimes: (i) ω−2 at higher frequencies for all values of Ro and (ii) ω−γ1 at intermediate frequencies with γ1 ≈ 4 for Ro > 1, while 4 < γ1 < 6.6 for 0.2 ≤ Ro < 1.

PACS numbers: 47.27.te, 47.27.ek, 47.27.er

In the Kolmogorov picture (K41) of homogeneous isotropic turbulence, kinetic energy is dissipated at short length scales (large wave numbers k) by viscosity. For a statistically steady state to be obtained, the kinetic energy is injected at large length scales at a constant rate which is also the dissipation rate. Far away from either end is the inertial range through which the nonlinear terms of the Navier-Stokes equation transfer the energy from one scale to another at a constant rate εK = dK/dt, where K = ∫ E(k)dω = ∫ dkdω Ck(k, ω) is the kinetic energy per unit mass and Ck(k, ω) is the wave number k and frequency ω dependent velocity correlation function. The object εK is thus the kinetic energy flux. In the inertial range, E(k) is dependent only on wave number k and εK. A dimensional analysis leads to E(k) ~ k−5/3 (K41). In general, E(k) = 4πk−5/3 ∫ Ck(k, ω)dω ∝ k−6. Scaling implies Ck(k, ω) = k−2−α−γf(ω/kγ), where kγ is a characteristic frequency. A dimensional argument yields the exponent ζ = 2/3 in K41.

In convective turbulence 2,3, one expects that there will be a regime where temperature fluctuations δT, rather than velocity fluctuations v, will control the spectrum. It was shown by L’vov 4 that for small temperature fluctuations, the expansion of the mean convective entropy Φ ∝ ∫ (δT)2dω, where r is the space variable. The entropy will be conserved in the absence of thermal diffusion and forcing. In the so called Bolgiano-Obukhov picture (BO) in the corresponding inertial range, E(k) is determined by k and the rate of dissipation of the entropy εΦ = dΦ/dt which is equal to the flux of the convective entropy through different scales. Here E(k) is determined by k, εΦ and α0g, where α0 is the thermal expansion coefficient. One gets E(k) ~ k−11/5, which gives α = 11/5 in this case. The corresponding ζ is known to be 2/5. There will be a convective entropy spectrum EΦ(k) as well defined by Φ = ∫ EΦ(k)dω. Dimensional analysis establishes that the entropy spectrum EΦ(k) ~ k−7/5.

In any realistic situation K41 [E(k) ~ k−5/3] and BO [E(k) ~ k−11/5] will both be present with K41 holding at high wave numbers and BO at smaller ones. The two exponents are quite close to each other and attempts to go to small enough k to get into the BO regime has been thwarted by the system size. Consequently, we decided to explore the spectra in frequency space instead.

The frequency spectra E(ω) for the kinetic energy and EΦ(ω) for the convective entropy are defined as: K = ∫ E(ω)dω and Φ = ∫ EΦ(ω)dω. In terms of correlation functions E(ω) = 4π ∫ k2Cκ(k, ω)dω and EΦ(ω) = 4π ∫ k2CΦ(k, ω)dω. Insertion of the scaling form for Ck for K shows E(ω) ~ ω−2 for K41 and ω−4 for BO. On the other hand the scaling form for CΦ shows EΦ(ω) ~ ω−2 for BO and ω−4 for K41. In reality E(ω) and EΦ(ω) get contributions from both K41 and BO, and to the lowest order we find that the two contributions add. The relative contributions of K41 and BO for E(ω) and EΦ(ω) are of a similar form, with BO a weaker contribution. We write E(ω) ~ ω−2 + c0ωγ4ω−4, where c0 < 1 for a weak BO contribution, while ωγ depends on system parameters. For the convective entropy, EΦ(ω) ~ c0ωγ4ω−4 + ω2ω−4. For E(ω), the crossover frequency is ωk = ωc0√c0 and for EΦ(ω) it is ωk = ωc0/√c0. Since c0 < 1, the crossover should occur earlier for EΦ(ω). The dependence of c0 on the rotation rate cannot be predicted.

We present the results of direct numerical simulations (DNS) on the frequency spectra of the convective entropy EΦ(ω) and the kinetic energy E(ω) along with the power spectrum of the heat flux PJPr(ω) for low-Prandtl-number Rayleigh-Bénard convection (Pr < 0.6) with uniform rotation about the vertical axis. Simulations are done for a wide range of the convective Rossby number RO = √Rα/(TaPr) (0.2 ≤ RO < ∞). The power spectra of all the three quantities show two scaling regimes: The spectra scale with frequency ω as ω−γ1 at intermediate frequencies and as ω−2 at higher frequencies. The scaling exponent γ1 depends on RO, Ra and Pr. It is found that 3.0 < γ1 < 4.4 for RO > 1 and 4.0 < γ1 < 6.6 for 0.2 ≤ RO < 1. There is no scaling behavior observed at lower frequencies.

We consider thermal convection in a thin horizontal layer of fluid of thickness d, kinematic viscosity ν, thermal diffusivity κ, and rotating uniformly about a ver-

The spectra show two scaling regimes: (i) $f$-frequencies for the power spectra of three global quantities: the entropy, the kinetic energy, and the Nusselt number. The upper and lower black straight lines show the scaling behavior as $f^\gamma$ with the exponent $\gamma$. The inset shows the variation of the exponent $\gamma$ at intermediate frequencies and $\gamma_2$ at higher frequencies for the power spectra of three global quantities: the entropy, the kinetic energy, and the Nusselt number.

### Table I: List of the convective Rossby number $Ro = \sqrt{Ra/(TaPr)}$

| Ro  | Pr  | $r$ | $Ra$          | $\gamma_1^\Phi$ | $\gamma_2^\Phi$ | $\gamma_1$ | $\gamma_2$ | $\gamma_{Nu}^1$ | $\gamma_{Nu}^2$ |
|-----|-----|----|---------------|------------------|------------------|-------------|-------------|-----------------|-----------------|

**FIG. 1:** (Color online) Frequency spectra $E_\Phi(\omega)$ of the spatially averaged convective entropy computed from DNS for different values of $Ro$ (curves of different colors). The spectra show two scaling regimes: (i) $E_\Phi(\omega)$ scales as $\sim \omega^{-\gamma_1}$ at the moderate frequencies, with the exponent $\gamma_1^\Phi$ showing a weak dependence on $Ro$ for $Ro > 1$ ($3.37 \leq \gamma_1 \leq 4.30$), and a strong dependence on $Ro$ for $Ro < 1$ ($3.93 \leq \gamma_1 \leq 6.59$). (ii) $E_\Phi(\omega)$ scales with $\omega$ as $\sim \omega^{-\gamma_2}$ with $\gamma_2^\Phi \sim 2$ at higher frequencies for all values of $Ta$, $Pr$, and $Ro$ considered here. The upper and lower black straight lines show the scaling behavior as $\omega^{-2}$ and $\omega^{-2}$, respectively. The inset shows the variation of the exponent $\gamma_1^\Phi$ with $Ro$.

Rayleigh number $Ra = \alpha_0 \Delta T g d^3/(\nu \kappa)$, the Taylor number $Ta = 4 \Omega^2 d^4/\nu^2$, and the Prandtl number $Pr = \nu/\kappa$. We consider thermally conducting and stress-free conditions on the top and bottom boundaries. This leads to...
the boundary conditions: \( \partial_z v_1 = \partial_z v_2 = v_3 = \theta = 0 \) at \( z = 0 \) and \( z = d \). The boundary conditions in the horizontal direction are considered to be periodic. We then numerically integrate the dimensionless hydrodynamic system using pseudo spectral method (see for details [6]). We use long signals for more than 150 dimensionless time units with grid resolutions of 256\(^3\) for this purpose. The data points from the computed signals are recorded at equal time steps of 0.001 to determine frequency spectra. A time-dependent convection appears at onset as \( Ra \) is raised above a critical value \( Ra_c(Ta, Pr) \) for the values of \( Ta \) and \( Pr \) considered here. The flow becomes unsteady even at smaller values of the reduced Rayleigh number \( r = Ra/Ra_c(Ta, Pr) > 5 \) for \( Pr < 0.6 \).

Figure 4 displays the frequency spectrum of the entropy of the turbulent flow \( E_s(\omega) \), which scales with \( \omega \) approximately as \( \omega^{-\gamma_1} \) with \( 3.4 \leq \gamma_1 \leq 6.6 \) at intermediate values of the dimensionless frequencies (0.07 < \( \omega/(2\pi) \) < 0.70). The scaling exponent \( \gamma_1 \) shows a relatively weak dependence on \( Ro, Pr, Ta \) and \( r \) at intermediate frequencies for \( Ro > 1 \). The value of \( \gamma_1 \) obtained here is in good agreement with the scaling exponent observed in an experiment without rotation by Cioni et al. [7] for turbulent convection in a very low-Prandtl-number fluid. The exponent \( \gamma_1 \) increases sharply as \( Ro \) decreases (see the inset in Fig. 4) for \( Ro < 1 \). The exponent \( \gamma_1 \) varies between 4 and 6.6 for 0.2 \( \leq Ro < 1 \). The unsteady convection at smaller values of \( Ro \) (typically, \( r < 50 \)) is unlikely to be in a statistical steady state. This makes the exponent \( \gamma_1 \) non-universal for flows at \( Ro < 1 \). The spectrum shows a different scaling at higher frequencies (0.7 \( \leq \omega/(2\pi) \) \( \leq 200 \)). \( E_s(\omega) \) clearly scales with \( \omega \) as \( \omega^{-\gamma_1} \) with \( 1.96 \leq \gamma_1 \leq 1.98 \). The power spectra of the temperature fluctuations showing \( \omega^{-2} \) behavior was clearly observed in experiments by Boubnov and Golitsyn [8]. The scaling extends for almost two decades, and it is independent of \( Ro, Pr, Ta \) and \( r \) at higher frequencies. Zhou and Xia [9] [see Fig. 1 (b) therein] observed \( E_\theta(\omega) \sim \omega^{-2} \) at higher values of \( Ra \) in the absence of rotation. The exponents \( \gamma_1 \) and \( \gamma_2 \) extracted by fitting the data for entropy spectra obtained from DNS are listed in Table II for several values of \( Ro, Pr, \) and \( r \).

Figure 2 displays the frequency spectrum of the energy \( E(\omega) \) for different values of \( Ro \). The \( E(\omega) \) also shows two scaling regimes. It scales with \( \omega \) as \( \omega^{-\gamma_1} \) with 3.06 \( \leq \gamma_1 \leq 6.54 \) at intermediate frequencies. The scaling exponent \( \gamma_1 \) shows a weak dependence on \( Ro, Pr, Ta \) and \( r \) for \( Ro > 1 \). Like \( \gamma_1, \gamma_1 \) increases sharply with a decrease in \( Ro \) for \( Ro < 1 \) (Fig. 2 inset). The energy power spectrum shows very clear scaling at higher frequencies. \( E(\omega) \) scales with \( \omega \) as \( \omega^{-\gamma_2} \) with \( \gamma_2 \sim 2 \). The scaling exponent \( \gamma_2 \), which is independent of \( Ro, Pr, Ta \), and \( r \), extends for more than two decades in \( \omega \). The results of the best fit for \( \gamma_1 \) and \( \gamma_2 \) are listed in the seventh
at intermediate frequencies and flux (Nu) across the fluid layer. The power spectrum
of different values of Ro. The power spectrum $P_{\text{Nu}}(\omega)$ shows two scaling regimes: $P_{\text{Nu}}(\omega)$ scales as $\omega^{-\gamma_1^{\text{Nu}}}$ with $3.57 \leq \gamma_1^{\text{Nu}} \leq 6.35$ at intermediate frequencies and $\omega^{-\gamma_2^{\text{Nu}}}$ with $\gamma_2^{\text{Nu}} \sim 2$ at higher frequencies. The inset shows the variation of $\gamma_1^{\text{Nu}}$ with Ro.

$P_{\text{Nu}}(\omega)$ also shows two scaling regimes (Fig. 3). It scales with $\omega$ as $\omega^{-\gamma_1^{\text{Nu}}}$ with $3.57 < \gamma_1^{\text{Nu}} < 6.35$ at intermediate frequencies, and it scales as $\omega^{-\gamma_2^{\text{Nu}}}$ with $\gamma_2^{\text{Nu}} \sim 2$ at high frequencies. The experiments by Aumaître and Fauve [10] showed that the power spectra of the temporal fluctuations of the heat flux scaled as $\sim \omega^{-2}$ in the central part of the Rayleigh-Bénard cell and as $\sim \omega^{-4}$ near the boundaries in the absence of rotation. The results of the best fit are listed in the ninth and the tenth columns of Table I. The exponent $\gamma_1^{\text{Nu}}$ increases as Ro decreases for Ro $< 1$ (Fig. 3 inset), as in the case of frequency spectra of the entropy and energy. The flow is far away from fully developed turbulence. We do not have an answer based on dimensional analysis for scaling exponents of the power spectrum of Nu.

Variations of the time averaged energy $\bar{K}$ and Nu with Ta are shown in Fig. 4 for different values of Pr and $r$. The time averaged energy $\bar{K}$ varies with $\text{Ta} \sim \text{Ta}^{-0.2}$ for fixed values of Pr and $r$. It is consistent with the scaling used for the simulations. The dimensionless energy $\bar{K} = K d^2 / (\nu \kappa \text{Ra}) = K d^2 / [\nu \kappa \text{Ra}_c(Ta)]$ decreases with $\text{Ta}$ as $\text{Ra}_c(Ta)$ increases with $\text{Ta}$ for a fixed values of $r$. The Nusselt number, on the other hand, varies with $\text{Ta}$ as $\text{Ta}^{0.13}$ for fixed values of $r$ and Pr. This is also consistent, as $\text{Ra}$ has to be increased with increasing $\text{Ta}$ at a fixed value of $r$. This leads to an increase in Nu with $\text{Ta}$.

We have also computed the power spectrum of the heat flux (Nu) across the fluid layer. The power spectrum

and eighth columns of Table I. A comparison of crossover frequencies shows that $\omega_c < \omega_\Phi$, as had been anticipated for $\text{Ro} \rightarrow \infty$. There is a weak dependence of $c_0$ on $\text{Ro}$.

We have also computed the power spectrum of the heat flux (Nu) across the fluid layer. The power spectrum

Fig. 3: (Color online) Power spectra of temporal fluctuations of the heat flux (Nusselt number Nu), as computed from DNS, for different values of Ro. The power spectrum $P_{\text{Nu}}(\omega)$ shows two scaling regimes: $P_{\text{Nu}}(\omega)$ scales as $\omega^{-\gamma_1^{\text{Nu}}}$ with $3.57 \leq \gamma_1^{\text{Nu}} \leq 6.35$ at intermediate frequencies and $\omega^{-\gamma_2^{\text{Nu}}}$ with $\gamma_2^{\text{Nu}} \sim 2$ at higher frequencies. The inset shows the variation of $\gamma_1^{\text{Nu}}$ with Ro.

Fig. 4: (Color online) (a) Mean energy $\bar{K}$ and (b) Nusselt number Nu scale with Taylor number Ta as $\text{Ta}^{-0.19}$ and $\text{Ta}^{0.13}$, respectively.
frequency spectra of convective entropy and kinetic energy along with the power spectrum of the heat flux for the turbulent flow in low-Prandtl-number Rayleigh-Bénard convection with uniform rotation. The spectra show two very different scaling regimes: $\omega^{-\gamma_1}$ at moderate frequencies and $\omega^{-\gamma_2}$ at relatively higher frequencies. The scaling exponent $\gamma_1$ at moderate frequencies shows a weak dependence on $Ro$ for $Ro > 1$ with $\gamma_1 \sim 4$, but shows a strong dependence on $Ro$ for $Ro < 1$. The scaling exponent $\gamma_2 \approx 2$ at higher frequencies is independent of $Ro$. The frequency spectra of global quantities rather than local ones appear to make both the Kolmogorov and Bolgiano-like regimes more accessible.

We thank S. Fauve (ENS, Paris) for fruitful discussions.
