State Estimation for Piecewise Affine State-Space Models

Rafael Rui, Tohid Ardeshiri, Henri Nurminen Student Member, IEEE, Alexandre Bazanella, Senior Member, IEEE, and Fredrik Gustafsson, Fellow, IEEE

Abstract—We propose a filter for piecewise affine state-space (PWASS) models. In each filtering recursion, the true filtering posterior distribution is a mixture of truncated normal distributions. The proposed filter approximates the mixture with a single normal distribution via moment matching. The proposed algorithm is compared with the extended Kalman filter (EKF) in a numerical simulation where the proposed method obtains, on average, better root mean square error (RMSE) than the EKF.

Index Terms—Piecewise affine, state-space models, nonlinear filtering, Kalman filtering.

I. INTRODUCTION

We consider a class of stochastic hybrid models in which the switch between submodels is not a jump Markov process, but it is state dependent. In hybrid models, the state domain can be divided into a number of regions, and within each region, the state dynamics are described by a set of differential equations. Here we will deal with piecewise affine state-space (PWASS) models. PWASS models are a particular case of stochastic hybrid models, which are used to approximate nonlinear dynamical systems and have been considered in several fields, such as automatic control [1], signal processing [2], system biology [3], and computer vision [4].

Most of studies in the literature on Bayesian filtering of stochastic hybrid systems are limited to jump Markov systems [5]–[10] or the so called semi-Markov jump linear systems [11], [11]–[13]. However, in practice, there are systems where the jump Markov model for transitions between submodels is an approximation of the reality. For example, in the JAS 39 Gripen aircraft, the dynamic of the pitch rate in the model for the flight dynamic in the longitudinal direction has a nonlinear dependence on the angle of attack [14]. Further, this nonlinear dependence is modeled by a piecewise affine function.

Fig. 1. A piecewise affine function is locally approximated by a single line in EKF, while the proposed filter computes the first two moments of the posterior over the entire support.

The exact Bayesian filtering solution for such systems is a mixture of truncated normal distributions, where the number of mixture components grows exponentially with time. When the extended Kalman filter (EKF) is used in PWASS models, the piecewise affine function is approximated by a single line, as showed in Fig. 1. This is problematic when the state uncertainty is large compared to the sizes of the regions. In this letter, we propose a Bayesian filtering algorithm for PWASS models that uses the exact time and measurement Kalman filter updates for each submodel avoiding linearization errors. In the proposed filter the cumulative distribution function (CDF) is used to compute the posterior distribution of the state as well as the probability of each region (shaded area in Fig. 1). The mixture explosion is avoided through approximating each posterior mixture of truncated normal distributions by a single normal distribution with matched moments.

II. PROBLEM FORMULATION

Consider the PWASS model [15]

\[
\begin{align*}
\mathbf{x}_{t+1} &= \mathbf{F}(\mathbf{x}_t) + B \mathbf{u}_t + \mathbf{\omega}_t, \quad (1a) \\
\mathbf{y}_t &= C \mathbf{x}_t + \mathbf{\nu}_t, \quad (1b)
\end{align*}
\]

where \(\mathbf{y}_t \in \mathbb{R}^{n_y}\) is the measurement; \(C \in \mathbb{R}^{n_y \times n_x}\) is the measurement matrix; \(\mathbf{u}_t \in \mathbb{R}^{n_u}\) is the deterministic input; \(B \in \mathbb{R}^{n_x \times n_u}\) is the input matrix; \(\mathbf{\omega}_t \in \mathbb{R}^{n_w}\) and \(\mathbf{\nu}_t \in \mathbb{R}^{n_v}\) are the process and measurement noise terms respectively; \(\mathbf{x}_t \in \mathbb{R}^{n_x}\) is the state vector partitioned by two scalar variables \(\eta_t\) and \(\zeta_t\) as well as a vector \(\mathbf{\chi}_t \in \mathbb{R}^{(n_x-2)}\) as in \(\mathbf{x}_t \triangleq [\eta_t, \zeta_t, \mathbf{\chi}_t^T]^T\).
The nonlinear function $F(\cdot)$ is the state transition function with the following structure

$$F(x_t) = \begin{bmatrix} \Phi^T x_t \\ F x_t \end{bmatrix},$$

where $z_t = \begin{bmatrix} \zeta_t \ T \end{bmatrix}^T,$ $\Phi \in \mathbb{R}^{(n_x-1)}$, $\Phi \in \mathbb{R}^{n_x}$, $F \in \mathbb{R}^{(n_x-2) \times n_x}$, and the piecewise affine function $f(\eta_t)$ is given by

$$f(\eta_t) = \begin{cases} f_1 = a_1 \eta_t + b_1 & \text{if } l_1 < \eta_t \leq l_2 \\ \vdots \\ f_{N_x} = a_{N_x} \eta_t + b_{N_x} & \text{if } l_{N_x} < \eta_t < l_{N_{x}+1}, \end{cases}$$

with $l_1 = -\infty$ and $l_{N_{x}+1} = +\infty$. For a given region $R_{x_t} \triangleq \{x_t: l_1 \leq \eta_t \leq l_{t+1}\}$ it is possible to rewrite (2) using (3) as

$$F(x_t) = \begin{bmatrix} \Phi^T x_t \\ \Phi^T \end{bmatrix} = \begin{bmatrix} \Phi^T x_t \\ a_1 \eta_t + b_1 \end{bmatrix},$$

$$= A x_t + b_i.$$

Hence, for a given region $R_{x_t}$, the model (1) can be written as the conditionally affine state-space model

$$x_{t+1} = A x_t + B u_t + b_i + \omega_t,$$

$$y_t = C x_t + \nu_t,$$

where $A_i$ and $b_i$ are defined in (5). The index $i$ is $\{1, \cdots, N_x\}$ determined in which piecewise affine dynamics the system is at time $t$, i.e., which submodel is active at time $t$. The initial state has a prior distribution with mean $\mu$ and covariance $\Sigma$, and the subscript "1\{1\}" is read "at time 1" using measurements up to time $t_0$. Also, we assume $\{\omega_t \in \mathbb{R}^{n_\omega} \mid 1 \leq t \leq T\}$ and $\{\nu_t \in \mathbb{R}^{n_\nu} \mid 1 \leq t \leq T\}$ are mutually independent white Gaussian noise sequences with covariance $Q$ and $R$ respectively. In this letter, we propose a filter to estimate $p(x_t|y_{1:t})$.

III. PROPOSED SOLUTION

Assume that at time $t$ the following filtering posterior distribution for $x_t$ is available

$$p(x_t|y_{1:t}) = \mathcal{N}(x_t; \tilde{x}_{t|t}, \Sigma_{t|t}).$$

This distribution can be rewritten using the indicator function as in

$$p(x_t|y_{1:t}) = \sum_{i=1}^{N_x} 1_{A_{t}}(x_t) \mathcal{N}(x_t; \tilde{x}_{t|t}, \Sigma_{t|t}),$$

where

$$1_A(x) = \begin{cases} 1 & \text{if } x \in A, \\ 0 & \text{if } x \notin A. \end{cases}$$

Using (7), the state transition density $p(x_{t+1}|x_t)$ and the likelihood function $p(y_{t+1}|x_{t+1})$ can be written as

$$p(x_{t+1}|x_t) = \mathcal{N}(x_{t+1}; A x_t + B u_t + b_i, Q),$$

$$p(y_{t+1}|x_{t+1}) = \mathcal{N}(y_{t+1}; C x_{t+1}, R).$$

Therefore, the joint posterior $p(x_t, x_{t+1}, y_{1:t})$ can be written as

$$p(x_t, x_{t+1}, y_{1:t}) = \sum_{i=1}^{N_x} 1_{A_t}(x_t) \mathcal{N}(x_t; \tilde{x}_{t|t}, \Sigma_{t|t}) \times \mathcal{N}(x_{t+1}; A x_t + B u_t + b_i, Q) \mathcal{N}(y_{t+1}; C x_{t+1}, R),$$

which can be rewritten in matrix form as

$$p(x_t, x_{t+1}, y_{1:t}) = \sum_{i=1}^{N_x} 1_{A_t}(x_t) \mathcal{N}(x_t^T, x_{t+1}^T, y_{1:t}^T; \mu_{t,i}, \Sigma_{t,i}),$$

where

$$\mu_{t,i} = \begin{bmatrix} \mu_{t,1} \\ \mu_{t,2i} \end{bmatrix} = \begin{bmatrix} A x_t + B u_t + b_i \\ C A x_t + C (B u_t + b_i) \end{bmatrix},$$

$$\Sigma_{t,i} = \begin{bmatrix} \Sigma_{t,11} & \Sigma_{t,12} \\ \Sigma_{t,21} & \Sigma_{t,22} \end{bmatrix} = \begin{bmatrix} P_t (x_t^T, x_{t+1}^T, y_{1:t}^T; \mu_{t,i}, \Sigma_{t,i}) \\ C (A x_t + C (B u_t + b_i) \end{bmatrix}.$$

The conditional distribution of $x_t$ and $x_{t+1}$ given $y_{1:t+1}$ is

$$p(x_t, x_{t+1}|y_{1:t+1}) = \frac{1}{Z_t} p(x_t, x_{t+1}; y_{1:t+1}|y_{1:t})$$

$$= \frac{1}{Z_t} \sum_{i=1}^{N_x} 1_{A_t}(x_t) \mathcal{N}(x_t^T, x_{t+1}^T, y_{1:t}^T; \mu_{t,i}, \Sigma_{t,i}),$$

where

$$\tilde{\mu}_i = \begin{bmatrix} \mu_{t,1} \\ \mu_{t,2i} \end{bmatrix} = \mu_{t,1} + \Sigma_{t,11}^{-1} \Sigma_{t,12} (y_{1:t} - \mu_{t,2i}),$$

$$\tilde{\Sigma}_i = \begin{bmatrix} \tilde{\Sigma}_{11} & \tilde{\Sigma}_{12} \\ \tilde{\Sigma}_{21} & \tilde{\Sigma}_{22} \end{bmatrix} = \Sigma_{t,11} - \Sigma_{t,12} \Sigma_{t,22}^{-1} \Sigma_{t,21},$$

and

$$Z_t$$ is a normalizing constant, and the partitions in (21) and (22) have equal dimensions. The quantities $Pr(x_t \in R_t|y_{1:t+1})$ for $i = 1, \cdots, N_x$ as well as the normalizing constant $Z_t$ can be computed via integration of $p(x_t, x_{t+1}|y_{1:t+1})$ as in

$$Pr(x_t \in R_t|y_{1:t+1}) = \frac{1}{Z_t} \mathcal{N}(y_{1:t+1}; \mu_{t,i}, \Sigma_{t,i}) \int_{R_t} \mathcal{N}(x_t; \tilde{\mu}_i, \tilde{\Sigma}_i) \, dx_t$$

$$= \frac{1}{Z_t} \mathcal{N}(y_{1:t+1}; \mu_{t,i}, \Sigma_{t,i}) \Gamma_t,$$
where
\[ 
\Gamma_i = \int_{l_i < \eta_i < l_{i+1}} N(\eta_i; [\mu_{11}], [\Sigma_{11}]) \, d\eta_i 
\]
\[ 
= \frac{1}{2} \text{erf} \left( \frac{l_i - [\mu_{11}]}{\sqrt{2[\Sigma_{11}]}} \right) - \frac{1}{2} \text{erf} \left( \frac{l_{i+1} - [\mu_{11}]}{\sqrt{2[\Sigma_{11}]}}, \right) 
\]
where the \( \text{erf}(\cdot) \) is the error function, \( [\Sigma_{(i,j)}] \) is the element in row \( i \) and column \( j \) of \( \Sigma \), and
\[ 
Z_i = \sum_{i=1}^{N_i} N(y_{t+1}; \mu_2, \Sigma_{22}) \, \Gamma_i . 
\]

The probability \( \text{Pr}(x_t | y_{1:t+1}) \) represents the probability that the state be in the region \( R_i \) at time \( t \) given all information up to time \( t + 1 \). The filtering posterior distribution \( p(x_{t+1} | y_{1:t+1}) \) can be computed via the integration
\[ 
p(x_{t+1} | y_{1:t+1}) = \frac{1}{Z_{t+1}} \int p(x_t, x_{t+1}, y_{t+1} | y_{1:t}) \, dx_t 
\]
\[ 
= \frac{1}{Z_{t+1}} \sum_{i=1}^{N_i} N(y_{t+1}; \mu_2, \Sigma_{22}) 
\times \int_{R_i} 1_{R_i}(x_t) N([x_t^T, x_{t+1}^T]^T; \mu_i, \Sigma_i) \, dx_t . 
\]

The joint posterior distribution on the right-hand side of (29) is a mixture of doubly truncated multivariate normal distributions (DTMDN) [16]. In order to have a recursive algorithm, the posterior will be approximated by a normal distribution. To this end, the mean and the covariance of the posterior distribution \( p(x_{t+1} | y_{1:t+1}) \) is needed. The mean and covariance of a mixture distribution can be computed using the mean and the covariance of the components of the mixture density via standard moment matching formulas [17]. Hence, the problem boils down to computing the mean and the covariance of the DTMDN which is presented in the Appendix A.

The proposed filter for PWASS models will be referred to by PAKF (Piecewise Affine Kalman Filter). The filtering recursion is given in TABLE I. The expressions for computing the mean and the covariance of a DTMDN for a given region \( R_i \) are given in the lines 18 and 19 of TABLE I. The probabilities \( \text{Pr}(x_t | y_{1:t+1}) \) as well as the normalizing constant \( Z_t \) are calculated in the lines 21 and 22 and are used within the moment matching whose formulas are given in the lines 23 and 24 of TABLE I.

### IV. Numerical Simulations

Numerical simulations are performed to evaluate the performance of PAKF. In these simulations, PAKF is compared to the extended Kalman filter (EKF) and the marginalized particle filter (MPF) [18, 19]. The EKF expressions for PWASS models are those in the lines 3-9 of TABLE I. In EKF, they are evaluated only for the region where \( \tilde{x}_{t|t} \) is located at time \( t \). The MPF is used to compute the optimal Bayesian solution. This optimal solution will be used as a reference in the evaluation of PAKF. All numerical computations are done using MATLAB.

Nonlinear vibrations caused by clearance can be modeled as a single-degree-of-freedom system (SDOFS) with piecewise affine spring characteristics [20]. Table II shows the physical model of SDOFS and Fig. 3 presents its piecewise affine spring characteristic. The discretized PWASS model for the SDOFS can be written as
\[ 
x_{t+1} \overset{\text{P}}{=} \eta_t + \zeta_t, 
\]
\[ 
y_t = \left[ \begin{array}{c} \eta_t \\ \zeta_t \end{array} \right], 
\]
where \( \eta_t \) and \( \zeta_t \) are the position in [mm] and the velocity in [mm/s] of the mass \( M \), respectively, \( \Delta t \) is the sampling time.
\( D \) is the damping coefficient, and \( a_i \) and \( b_i \) are the piecewise affine spring coefficients such that

\[
f(\eta_t) = \begin{cases} 
  f_1 = a_1 \eta_t + b_1 & \text{if } -\infty < \eta_t \leq l_1 \\
  f_2 = a_2 \eta_t + b_2 & \text{if } l_1 < \eta_t \leq l_2 \\
  f_3 = a_3 \eta_t + b_3 & \text{if } l_2 < \eta_t < +\infty
\end{cases}
\]  

(31)

with \( a_3 = a_1, b_1 = l_1(a_2 - a_1), b_2 = 0 \) and \( b_3 = l_2(a_2 - a_3) \). Monte Carlo (MC) simulations are performed, where the model (30) is simulated for \( T = 400 \) time steps. The parameters values are given in TABLE III. Further, \( x_t \) is sampled from standard bivariate normal distribution, \( \nu_t \sim N(0, 1) \), \( \omega_t \sim N([0\ 0]^T, \text{diag}[0.01\ 0.01]) \) and \( u_t \sim N(0, 5^2) \). For the MPF, we use 10,000 particles.

We compare the three filters in terms of the root mean square error (RMSE) between the true state and the predicted state

\[
\text{RMSE}(x_t) = \sqrt{\frac{1}{2T} \sum_{t=1}^{T} (\eta_t^{(j)} - \hat{\eta}_t^{(j)})^2 + (\zeta_t^{(j)} - \hat{\zeta}_t^{(j)})^2},
\]  

(32)

where \( \hat{\eta}_t^{(j)} = \begin{bmatrix} \hat{\eta}_{t_1}^{(j)} & \hat{\eta}_{t_2}^{(j)} \end{bmatrix}^T \) and \( x_t^{(j)} = \begin{bmatrix} \eta_t^{(j)} & \zeta_t^{(j)} \end{bmatrix}^T \) denote the estimated mean of the state \( x_t \) and its true value in the \( j \)th MC run, respectively. Columns two and three of Table III show the average over 5,000 MC simulations of RMSE (ARMSE) for each filter as well as the standard deviation of the RMSE (STD). We noticed that the ARMSE for PAKF is 5.35\% smaller than that of the EKF. The ARMSE for MPF is 0.12\% smaller than that of the PAKF. We also noticed that EKF has the highest STD of all the filters. The Fig. 4 presents the cumulative distribution of the RMSE for each filter. The minimum and maximum RMSE values for each filter are presented in the last two columns of TABLE III.

Fig. 3 shows the ARMSE between the simulated state and the estimated state as a function of time for the PAKF, MPF, and EKF. We noticed that the ARMSE for EKF is always above the ARMSE of PAKF and MPF. That is, PAKF and the MPF outperform EKF both for initial parts of the path and in the stabilized state. The MPF and PAKF have similar performance, but MPF is computationally expensive. For 10,000 particles, MPF takes six times more time to complete one MC run than PAKF.

**V. CONCLUSION**

The proposed filter (PAKF) obtains estimation error close to that of the optimal filter (MPF) for a particular class of PWASS models which are discussed in this letter. The filter’s performance is tested in an example where the measurement noise variance is greater than the process noise variances and the comparison filters are EKF and MPF. The filtering recursion of PAKF involves approximation of the posterior distribution.

APPENDIX A

MEAN AND COVARIANCE MATRIX OF DTMND

A doubly-truncated multivariate normal distribution (DTMND) is a multivariate normal distribution, where one component is truncated from both below and above. Without loss of generality, we assume that the double truncation is applied to the first component of the random vector. For numerical methods, evaluating the presented formulas requires evaluation of the Cholesky decomposition [21] Ch. 2.2.2] as well as the probability density function (PDF) and cumulative density function (CDF) of the univariate standard normal distribution.

A. Formulas for mean and covariance matrix

Let \( x \in \mathbb{R}^n \) be a random variable of the DTMND with the PDF

\[
p(x) \propto \mathcal{N}(x; \mu, \Sigma) \cdot 1_{[l_1,l_2]}(x),
\]

where \( \mu \in \mathbb{R}^n \) is the location parameter vector, \( \Sigma \in \mathbb{R}^{n \times n} \) is the positive definite square-scale matrix, and \( l_1, l_2 \in \mathbb{R} \) are the truncation limits. Further, let \( \Lambda \) be the lower triangular matrix for which \( \Sigma = \Lambda^T \) and whose diagonal entries are strictly positive. This type of square-root matrix can be obtained using the Cholesky decomposition [21] Ch. 2.2.2].

Then, the expectation value and covariance matrix of \( x \) are

\[
\begin{align*}
\mathbb{E}[x] &= \Lambda \left[ m^* \right] + \mu \\
\mathbb{V}[x] &= \Lambda \left[ s^* \right] \left[ \Lambda^T \right] \Lambda^{-1} \\
\end{align*}
\]

where

\[
\begin{align*}
m^* &= \frac{\phi(\lambda_1) - \phi(\lambda_2)}{Z}, \\
s^* &= 1 + \frac{\lambda_1 \phi(\lambda_1) - \lambda_2 \phi(\lambda_2)}{Z} - (m^*)^2,
\end{align*}
\]

with

\[
\lambda_1 = \frac{l_1 - \mu_1}{\lambda(1)}, \quad \lambda_2 = \frac{l_2 - \mu_1}{\lambda(1)}, \quad Z = \Phi(\lambda_2) - \Phi(\lambda_1).
\]

B. Derivation

Let \( y \in \mathbb{R}^n \) be a DTMND with the PDF

\[
p(y) \propto \mathcal{N}(y; 0, I_n) \cdot 1_{[l_1,l_2]}(y).
\]

The components of \( y \) are independent, so the moments of \( y \) are obtained using the formula for the doubly-truncated univariate normal random variable [22] Ch. 10.1]. The mean and the covariance matrix are thus

\[
\begin{align*}
\mathbb{E}[y] &= \left[ m^* \right] \\
\mathbb{V}[y] &= \left[ s^* \right] \left[ \Lambda^T \right] \Lambda^{-1}
\end{align*}
\]

where \( m^* \) and \( s^* \) are those in (36) and (37).

Let now \( z = \Lambda y + \mu \). The PDF of \( z \) is then

\[
p_z(z) = p_y(\Lambda^{-1}(z - \mu)) \cdot \det \left( \frac{\partial \Lambda}{\partial z} \right).
\]
As $\Lambda$ is a lower triangular matrix, $[\Lambda^{-1}]_{(1,1:n)} = \begin{bmatrix} \frac{1}{\lambda_{1,1}} & 0 \\ 0 & \ddots & \ddots \\ & & \frac{1}{\lambda_{n-1,n-1}} \end{bmatrix}$, so

$y_1 = ([z_1] - [\mu_1])/[\Lambda]_{(1,1)}$. Thus, (40) becomes

\[
p_z(z) \propto N(\Lambda^{-1}(z - \mu); 0, I) \cdot \det(\Lambda)^{-1} \\
\quad \cdot 1_{[\lambda_1, \lambda_2]} \left( \frac{[z_1] - [\mu_1]}{[\Lambda]_{(1,1)}} \right)
\]

(41)

because $\Lambda \Lambda^T = \Sigma$, $l_i = [\Lambda]_{(1,1)} \lambda_i + [\mu_1]$ for $i \in \{1, 2\}$ and $[\Lambda]_{(1,1)}$ is positive. That is, $z$ has the same distribution as $x$, so the expected value and covariance matrix of $x$ are

\[
E[x] = E[z] = \Lambda E[y] + \mu \\
V[x] = V[z] = \Lambda V[y] \Lambda^T.
\]

(42)

(43)

(44)

By substituting (38) and (39) to (43) and (44), respectively, we get the formulas (34) and (35).
