Xanthogranulomatous inflammation is a form of chronic inflammation characterized by aggregation of lipid-laden foamy histiocytes that occurs most commonly in the kidney and gallbladder. Xanthogranulomatous endometritis (XGE) is rare—less than 30 cases have been reported worldwide [1-10], and none were in Korea. We report here two cases of XGE in Korea along with its cytologic findings, which have not been described previously.

**CASE REPORT**

**Case 1**

A 78-year-old woman presented with a chief complaint of yellow pus-like vaginal discharge for 15 days. She had a history of hypertension for 10 years and was on medication for heart failure. On ultrasonography, her uterus was found to be enlarged, and fluid collection was observed in the endometrial cavity. Cytologic examination of the endometrial fluid was negative for malignancy but revealed many neutrophils with scattered foamy histiocytes (Fig. 1A). Chronic active endometritis with xanthomatous inflammation was diagnosed on examination of the endometrial curettage specimen. Antibiotics were prescribed with a follow-up appointment.

Two months later, the patient presented with abdominal pain, chills, and vaginal bleeding. The patient showed signs of systemic inflammation and septic shock, with a blood neutrophil count of 25,020/mm³ (95.7%) and blood pressure of 60/40 mm Hg. Culture of an endometrial curettage specimen showed no bacterial growth, but blood culture produced *Escherichia coli* growth. Antibiotics were administered, and after the patient’s neutrophil count and vital signs normalized, hysterectomy with right salpingo-oophorectomy was performed.

On gross examination, the endometrial cavity was filled with blood clots and most of the endometrium was bright yellow (Fig. 1B). Microscopic examination of the endometrium showed a massive aggregation of foamy histiocytes admixed with lymphocytes, neutrophils, and plasma cells (Fig. 1C). No complications related to XGE have been noted in the 4 years since surgery.

**Case 2**

A high-grade squamous intraepithelial lesion was detected on the cervicovaginal smear of a 72-year-old woman. Ultrasound scanning revealed intrauterine fluid accumulation, and pyometra was suspected. Cytologic examination of the endometrial washing specimen revealed many neutrophils with scattered foamy histiocytes, and a few atypical cells, probably from the uterine cervix (Fig. 2A). Blood neutrophil count was 9,840/mm³ (81.8%). Endometrial fluid culture produced *Pseudomonas aeruginosa* growth. Hysterectomy with bilateral salpingo-oophorectomy was performed.

On gross examination, the endometrium was thickened and yellow in many areas (Fig. 2B). There was a 5.2-cm-sized fibroma in the right ovary. Microscopic examination showed massive aggregation of foamy histiocytes and lymphocytes in the endometrium (Fig. 2C). Early invasive squamous carcinoma was noted in the uterine cervix. The patient has been healthy for the 23 months since surgery.
DISCUSSION

XGE occurs mostly in postmenopausal women and is frequently associated with hematometra or pyometra. It can also occur after radiotherapy-induced endometrial or cervical tumor necrosis [1]. Cervical stenosis is presumed to contribute to the retention of hemorrhage or necrotic tissue [2].

The characteristic histological finding of XGE is the replacement of the endometrium by thick sheets of lipid-laden foamy histiocytes, although other inflammatory cells can also be present. In both of our cases, cytologic evaluation revealed many neutrophils with scattered foamy histiocytes, as seen on the microscopic findings of curettage and surgical specimens. Bacteria may or may not be isolated, but when related to bacterial infection, the

(C) Microscopic examination of the endometrium shows aggregation of foamy histiocytes admixed with lymphocytes, neutrophils, and plasma cells.
involved organisms include *Escherichia coli*, *Proteus vulgaris*, *Pectyostreptococcus magnus*, or *Enterococcus* spp. [3,4].

While cases of XGE might resolve spontaneously or with antibiotic treatment, progression to peritonitis or sepsis can lead to a poor prognosis. Systemic inflammation originating from endometritis resulted in septic shock in our 78-year-old patient. Noack et al. [4] reported a case of XGE that led to a fatal outcome because of transmural extension of inflammation.

Differential diagnoses of XGE include malakoplakia, also a rare entity of the female reproductive tract. The absence of pathognomonic Michaelis-Gutmann bodies can exclude a diagnosis of malakoplakia [5]. On radiologic imaging, XGE can mimic malignant neoplasia of the endometrium, with findings such as endometrial thickening or mass formation [6]. However, the pres-

ence of XGE does not exclude the possibility of co-existing malignancies [7]; therefore, extensive sectioning and thorough microscopic examination of the whole endometrium is recommended.

In conclusion, XGE is a rare but clinically important entity because of its capacity to mimic endometrial malignancy. Cytological evaluation can be useful in cases with unclear clinical presentations. XGE can be diagnosed in the absence of cells that are definite or suspicious for malignancy and in the presence of lipid-laden histiocytes and inflammatory cells such as neutrophils.
