We report improved measurements of branching fraction and decay constant $f_{D^+}$ in $D^+ \rightarrow \mu^+ \nu$ using 281 pb$^{-1}$ of data taken on the $\psi(3770)$ resonance with the CLEO-c detector. We extract a relatively precise value for the decay constant of the $D^+$ meson by measuring $\beta(D^+ \rightarrow \mu^+ \nu) = (4.40 \pm 0.66^{+0.09}_{-0.12}) \times 10^{-4}$ and find $f_{D^+} = (222.6 \pm 16.7^{+2.8}_{-3.4})$ MeV. We also set a 90% confidence upper limit on $\beta(D^+ \rightarrow e^+ \nu) < 2.4 \times 10^{-5}$ which limits contributions from non-standard model physics.

International Europhysics Conference on High Energy Physics
July 21st - 27th 2005
Lisboa, Portugal

*Speaker.
1. Introduction

The last 3 decades have witnessed amazing progress in Heavy Flavor physics. To test the SM and search for new physics, the precise measurements of CKM matrix elements have been one of the focus of current HEP efforts. However, our discovery potential is limited by our ability to relate the world of hadrons to the world of quarks, that is, the systematic errors due to non-pertubative QCD.

The CLEO-c program at \( \psi(3770) \) is an important part of the global efforts in heavy flavor physics. The precise measurements of decay constants \( f_{D^+} \) and \( f_{D_s} \) will test the Lattice QCD calculation and gain confidence in the theoretical prediction of \( f_B \). The decay \( D^+ \to \ell^+ \nu \) proceeds by the \( c \) and \( \bar{d} \) quarks annihilating into a virtual \( W^+ \), with a decay width \[ 1 \]

\[
\Gamma(D^+ \to \ell^+ \nu) = \frac{G_F^2}{8\pi} f_{D^+}^2 m_{D^+}^2 \left( \frac{1 - m_\ell^2}{M_{D^+}^2} \right)^2 |V_{cd}|^2 ,
\]

where \( M_{D^+} \) is the \( D^+ \) mass, \( m_\ell \) is the mass of the final state lepton, \( |V_{cd}| \) is a CKM matrix element that we assume to be equal to \( |V_{us}| \), and \( G_F \) is the Fermi coupling constant.

2. Data Sample and Event Selection

In this study \[ 2 \] we use 281 pb\(^{-1} \) of data produced in \( e^+e^- \) collisions using the Cornell Electron Storage Ring (CESR) and recorded at the \( \psi' \) resonance (3.770 GeV). Our analysis strategy is to fully reconstruct the \( D^- \) meson in one of six decay modes listed in Table \[ 1 \] and search for a \( D^+ \to \mu^+ \nu \) decay in the rest of the event. Track selection, particle identification (PID), \( \pi^0, K_S \), and muon selection cuts are identical to those used in Ref. \[ 3 \].

Table \[ 1 \] gives the numbers of signal and background events for each mode within the signal region, defined as \( m_D^2 - 2.5 \sigma_{m_{BC}} < m_{BC} < m_D^2 + 2.0 \sigma_{m_{BC}} \), where \( \sigma_{m_{BC}} \) is the r.m.s. width of the lower side of the distribution.

| Mode       | Signal | Background |
|------------|--------|------------|
| \( K^+ \pi^- \pi^- \) | 77387 ± 281 | 1868 |
| \( K^+ \pi^- \pi^- \pi^0 \) | 24850 ± 214 | 12825 |
| \( K_S \pi^- \) | 11162 ± 136 | 514 |
| \( K_S \pi^- \pi^- \pi^- \) | 18176 ± 255 | 8976 |
| \( K_S \pi^- \pi^0 \) | 20244 ± 170 | 5223 |
| \( K^+ K^- \pi^- \) | 6535 ± 95 | 1271 |
| Sum       | 158354 ± 496 | 30677 |

Table 1: Tagging modes and numbers of signal and background events.

Using our sample of \( D^- \) candidates we search for events with a single additional charged track presumed to be a \( \mu^+ \). The track must make an angle >35.9° with respect to the beam-line, deposit less than 300 MeV of energy in the calorimeter, characteristic of a minimum ionizing particle, and
1. Not be identified as a kaon. Then we infer the existence of the neutrino by requiring a measured value near zero (the \( \nu \) mass squared) of the missing mass squared defined as

\[
MM^2 = (E_{beam} - E_{\mu^+})^2 - (-p_{D^-} - p_{\mu^+})^2, \tag{2.1}
\]

where \( p_{D^-} \) is the three-momentum of the fully reconstructed \( D^- \).

In order to restrict the sample to candidate \( \mu^+ \nu \) events, we select events with only one charged track in addition to the tagging \( D^- \). Events with extra tracks originating within 0.5 m (radially) of the event vertex are rejected, as are events having a maximum neutral energy cluster of more than 250 MeV. These cuts are highly effective in reducing backgrounds especially from \( D^+ \to \pi^+ \pi^0 \) decays, but they introduce an inefficiency because the decay products of the tagging \( D^- \) can interact in the detector material leaving spurious tracks or clusters.

3. Results

The \( MM^2 \) distribution is shown in Fig. 1. We see a peak near zero containing 50 events within the interval \(-0.050 \text{ GeV}^2\) to \(+0.050 \text{ GeV}^2\), approximately \( \pm 2\sigma \) wide. The peak is mostly due to \( D^+ \to \mu^+ \nu \) signal. The large peak centered near 0.25 GeV\(^2\) is from the decay \( D^+ \to \bar{K}^0 \pi^+ \) that is far from our signal region and is expected, since many \( K_L \) escape our detector.

There are several potential background sources; these include other \( D^+ \) modes, misidentified \( D^0 \bar{D}^0 \) events, and continuum including \( e^+ e^- \to \gamma \psi' \). Hadronic sources need to be considered because the requirement of the muon depositing less than 300 MeV in the calorimeter, while about 99% efficient on muons, rejects only about 40% of pions or kaons as determined from a pure sample of \( D^0 \to K^- \pi^+ \) decays.
There are a few specific $D^+$ decay modes that contribute unwanted events in the signal region. Residual $\pi^+\pi^0$ background is determined from a simulation that uses a branching fraction of $(0.13\pm0.02)\%$ and yields $1.40\pm0.18\pm0.22$ events; the first error is due to Monte Carlo statistics, and the second is systematic, due mostly to the branching ratio uncertainty. We find background from $D^+\to\tau^+\nu$ only when $\tau^+\to\pi^+\nu$. Since the $\tau^+\nu$ branching ratio is known to be 2.65 times the $\mu^+\nu$ rate from Eq. 1.1, our simulation gives $1.08\pm0.15\pm0.16$ events, where the systematic error arises from our final uncertainty on the $\mu^+\nu$ decay rate. The $K^0\pi^+$ mode (branching ratio of $(2.77\pm0.18)\%$) gives a large peak in the $M^2$ spectrum near 0.25 GeV$^2$. While far from our signal region, the tail of the distribution can contribute. Our total background is $2.81\pm0.30\pm0.27$ events. We have $47.2\pm7.1^{+0.3}_{-0.3} \mu^+\nu$ signal events after subtracting background. The detection efficiency for the single muon of 69.4% includes the selection on $M^2$ within $\pm2\sigma$ limits, the tracking, the particle identification, probability of the crystal energy being less than 300 MeV, and corrections for final state radiation. It does not include the 96.1% efficiency of not having another unmatched cluster in the event with energy greater than 250 MeV. We also need to account for the fact that it is easier to find tags in $\mu^+\nu$ events than in generic decays by a small amount, $(1.5\pm0.4\pm0.5)\%$, as determined by Monte Carlo simulation.

Our result for the branching fraction, using the tag sum in Table 1, is

$$B(D^+\to\mu^+\nu) = (4.40\pm0.66^{+0.09}_{-0.12})\times10^{-4}.$$ (3.1)

The decay constant $f_{D^+}$ is then obtained from Eq. (1.1) using $1.040\pm0.007$ ps as the $D^+$ lifetime and $|V_{cd}|=0.2238\pm0.0029$ (3). (We add these two small additional sources of uncertainty into the systematic error.) Our final result is

$$f_{D^+} = (222.6\pm16.7^{+2.8}_{-3.4})\text{ MeV}.$$ (3.2)

We use the same tag sample to search for $D^+\to e^+\nu_e$. We identify the electron using a match between the momentum measurement in the tracking system and the energy deposited in the CsI calorimeter as well as insuring that the shape of the energy distribution among the crystals is consistent with that expected for an electromagnetic shower. Other cuts remain the same. We do not find any candidates, yielding a 90% C.L. limit of $B(D^+\to e^+\nu_e) < 2.4\times10^{-5}$.
