We succeeded in viewing the image of pancreatic duct on a TV monitor as a sequential electronic endoscope image by connecting a converter with a charge-coupled device to an ultra-thin pancreatoscope. Spacial image processing by adaptive enhancement, using an electronic endoscope, was studied in the pancreatoscope images of 18 cases (10 with pancreatic cancer and 8 with chronic pancreatitis). As a result, it became clear that the images obtained in Peak 2 of adaptive enhancement are much better than the original images. There was an excellent effect of clearly detecting the characteristic mucosal patterns in pancreatic cancer and chronic pancreatitis. We are convinced that this method would be very useful in improving the diagnostic ability of pancreatic cancer using an ultra-thin pancreatoscope.

Keywords: Pancreatoscope, pancreatic cancer, spacial image processing

INTRODUCTION

We clinically tried endoscopy of the main pancreatic duct in various pancreatic diseases by inserting an ultra-thin pancreatoscope through a cannula into the normal papilla of Vater[1]. There have been few sufficient diagnostic values for an ultra-thin pancreatoscope containing only 3000 optical image fibers and the small-sized images when compared with the conventional fiberscope used for the digestive system. We first succeeded in viewing the image of the pancreatic duct on a TV monitor as a sequential electronic endoscope image by connecting a converter with a high-grade charge-coupled device to an eyepiece of an ultra-thin pancreatoscope[2,3]. We then studied spacial image processing by adaptive enhancement, using an electronic endoscope, in the pancreatoscope images of cases with pancreatic cancer and chronic pancreatitis.

MATERIALS AND METHODS

An ultra-thin pancreatoscope with a 0.8mm external diameter, a sequential electronic endoscope (Olympus Co., Ltd., EVIS 200 system), special video converter (OVC 200), U-matic VTR (Sony Co., Ltd.), and image input processing system (Olympus IP system) were employed (Fig. 1A, 1B and 2). On the IP system, analog signals from the electronic endoscope are converted to digital signals, and then processed by personal computer (Fig. 3). The adaptive enhancement processing system (according to the statistical method) makes it possible to obtain a clearer image of the fine structure pattern of the mucosa[4]. Three peak frequencies were amplified to a maximum of twice,
3 times and 5 times respectively (Peak 2: twice, Peak 3: 3 times, Peak 5: 5 times).

A duodenal fiberoscope (JF 200, Olympus Co., Ltd.) was introduced into the second portion of the duodenum, and conventional pancreatography through a cannula (5F, 1.7mm) was performed. The cannula was further advanced under fluoroscopy into the tail of the pancreas. The ultra-thin pancreatoscope was then inserted into the cannula. When several millimeters of the tip of this scope emerged from the cannula, the lumen of the pancreatic duct was observed while saline was infused into the duct through the cannula (Fig. 4).

The pancreatic duct in pancreatic cancer and chronic pancreatitis was displayed, due to each of the 3 grades of enhancement processing, on the 14-inch TV monitor. The sharpness of the construction of the lesions, peripheral color and image quality were analyzed to compare with original images by three endoscopists.

PATIENTS

Eighteen cases (10 with pancreatic cancer and 8 with chronic pancreatitis) which undertook endoscopic examination by the ultra-thin pancreatoscope and the previous image processing from September 1992 to February 1995 were studied. Seven of the 10 patients with pancreatic cancer had carcinoma of the head of the pancreas, and the other 3 had carcinoma of the body or the tail of the pancreas. All patients agreed to participate in our study and signed an informed consent.
RESULTS

Images of irregular elevated lesions and friable mucosa with erosion were displayed in 8 of the 10 cases with pancreatic cancer. Extravascular compression with stenosis was disclosed in the other 2 patients. The former 8 cases, because of Peak 2 enhancement, demonstrated clearly uneven mucosa by malignant cell infiltration and peripheral color of the lesions (Fig. 5A, 5B and 5C, Fig. 6A, 6B and 6C).

A scar formation with smooth mucosa at stenotic areas was observed in 6 of the 8 cases with chronic pancreatitis. These 6 cases showed a marked enhancement effect of the fine structure of the duct (Fig. 7A, 7B and 7C). Additionally, protein plugs were displayed in 3 of the 8 cases with chronic pancreatitis. Half of all cases showed a favorable enhancement effect due to Peak 3 enhancement. Generally, image quality tended to be lower with a higher enhancement. This was the worst in Peak 5 (Table I).

DISCUSSION

We have been advancing a new endoscopic diagnosis for the pancreatic duct system since we reported the clinical application using an ultra-thin pancreatoscope
FIGURE 7A Diagnosis of chronic pancreatitis by ERCP. Stenosis with scar is endoscopically observed inside the lumen of the main pancreatic duct.

FIGURE 7B The enhanced image obtained in Peak 2 adaptive enhancement. Fine structure of the pancreatic mucosal pattern is well enhanced.

TABLE I Studies on the mucosal patterns of pancreatic cancer and chronic pancreatitis, using image processing

|                          | Peak2  | Peak3  | Peak5  |
|--------------------------|--------|--------|--------|
| Clarification of Sharpness of construction of lesions (n=14) | 14(100%) | 8(57%) | 0(0%) |
| Image color (n=10)       | 8(80%) | 5(50%) | 0(0%) |
| Poor image quality (n=14) | 0(0%)  | 9(64%) | 14(100%) |

in 1989[1,2]. Our fibroscope, with a 0.8mm external diameter, has been used routinely following endoscopic retrograde cholangiopancreatography (ERCP) at an outpatient clinic. This is because it is easy to insert into the normal papilla of Vater without endoscopic sphincterotomy.

This procedure makes it easier to clinicohistologically detect small lesions of the duct in malignant and chronic pancreatitis. We have stressed that it is very useful for the differentiation between local stenosis or elevated lesions of the main pancreatic duct in pancreatic cancer and chronic pancreatitis.

We devised to improve the image quality and visual potential of the ultra-thin pancreatoscope using a sequential video converter with a high-grade charge-coupled device[2]. This could make it easy to obtain a favorable image condition due to the sequential electronic scope system with excellent color reproducibility, and process images by a computer.

Using the IP system, we evaluated the sharpness of the construction of the lesions, peripheral color and
image quality in pancreatic cancer and chronic pancreatitis. We specifically used a 14-inch TV monitor, because it is hard to clearly detect images on a 35-mm slide[5]. Additionally, we studied real-time image processing on a TV monitor. The most favorable images were obtained in Peak 2 of adaptive enhancement, having an excellent effect to clearly detect the characteristic mucosal patterns in pancreatic cancer and chronic pancreatitis.

A new electronic endoscope containing real-time adaptive enhancement has been developed. We are convinced that this method would be very useful in improving the diagnostic ability of pancreatic cancer.
