Highlights
• This paper considers some of the properties of sequences \{v_{m,n}\}.
• The relationship between a generalized continued fraction and arbitrary sequence explored.
• This paper considers partial recurrence relation related to the third order recurrence relation.

Abstract
This paper explores a connection between third order recursive sequences and generalized continued fractions by analogy with second order recursive sequences and ordinary two-dimensional continued fractions. It does this with a partial recurrence relation which is related to the original third order recurrence relation, and raises a related conjecture.

Keywords
Fibonacci numbers
Tribonacci numbers
Partial quotients
Euclidean algorithm

1. INTRODUCTION
We define 3 basic 3rd order linear recursive sequences \{t_{m,n}\} m = 0,1,2 by initial values for \(n = 0,1,2\) and the 3rd order linear homogeneous recurrence relation
\[
t_{m,n} = P_1t_{m,n-1} + P_2t_{m,n-2} + P_3t_{m,n-3}, n \geq 3,
\] (1)
in which the \(P_i\) are arbitrary integers so that (1) is essentially analogous to Horadam’s generalized sequence for his 2nd order \{w_n\} [1]. For later convenience, we shall take the initial values as \(t_{m,0} = t_{m,1} = t_{m,2} = 1\) when \(P_1 = 0, P_2 = P_3 = 1\), a Padovan sequence [2] – sequence A00031 in Sloane [3].

We also define related arrays of sequences \{v_{m,n}\} for any integer \(m\) by a partial recurrence relation
\[
v_{m,n} = v_{m-1,n-1} + P_3v_{m-1,2}, 0 < m < 3, n > 0,
\] (2)
with boundary conditions
\[
v_{m,0} = P_3t_n \quad \text{and} \quad v_{0,n} = P_3^{-n}.
\] (3)
The purpose of this paper is to explore some of the properties of this array.

2. PARTIAL RECURRENCE RELATION

We first show that the characteristic equation associated with (1) is related to the partial recurrence relation by

\[ x^3 = \sum_{n=0}^{2} p_{3-n} x^n \rightarrow x^{m+3} = \sum_{n=0}^{2} v_{m,n} x^n \]

the proof of which follows by induction on \( m \).

When \( m = 0 \),

\[ \sum_{n=0}^{2} v_{0,n} x^n = \sum_{n=0}^{2} p_{3-n} x^n \]
\[ = x^3. \]

When \( m = 1 \),

\[ \sum_{n=0}^{2} v_{1,n} x^n = \sum_{n=0}^{2} (v_{0,n-1} + p_{3-n} v_{0,2}) x^n \]
\[ = x \sum_{n=0}^{2} v_{0,n-1} x^{n-1} + v_{0,2} \sum_{n=0}^{2} p_{3-n} x^n \]
\[ = x \sum_{n=0}^{2} v_{0,n} x^n + v_{0,2} x^3 \]
\[ = x \sum_{n=0}^{2} v_{0,n} x^n \]
\[ = x \sum_{n=0}^{2} p_{3-n} x^n \]
\[ = x^4. \]

Assume the result is true for \( m = 2, 3, \ldots, s \). Then

\[ x^{s+4} = \sum_{n=0}^{2} v_{s,n} x^{n+1} \]
\[ = v_{s,2} x^3 + \sum_{n=0}^{1} v_{s,n} x^{n+1} \]
\[ = v_{s,2} x^3 + \sum_{n=0}^{1} v_{s,n-1} x^n \]
\[ = v_{s,2} x^3 + \sum_{n=0}^{1} (v_{s+1,n} - p_{3-n} v_{s,2}) x^n \]
\[ v_{s,2} x^2 - v_{s,2} \sum_{n=0}^{2} P_{3-n} x^n + \sum_{n=0}^{2} v_{s+1,n} x^n \]

\[ = v_{s,2} (x^2 - P_3 - P_2 x - P_1 x^2) + \sum_{n=0}^{2} v_{s+1,n} x^n \]

\[ = \sum_{n=0}^{2} v_{s+1,n} x^n. \]

3. APPLICATION

We now apply this to the case where \( P_1 = 0, P_2 = P_3 = 1 \), which Hildebrand [4] used as an example in old-fashioned numerical analysis; that is, for

\[ x^6 = \sum_{n=0}^{2} v_{3,n} x^n = 1 + 2x + x^2. \]  

(5)

We also have from (4) that

\[ f(3) = x^3 \]

\[ = x + 1 \]

which is, in effect, the auxiliary equation for the corresponding third order Padovan sequence, some properties of which have been developed in [5-9]. If we apply the result (4), we see initially that

\[ f(3) = x + 1 \]

\[ f(4) = x^2 - x \]

\[ f(5) = x^3 - 2x + 1 \]

and so on by using (4) until

\[ f(48) = 170625 x^2 + 226030 x + 128801 \]

and

\[ f(49) = 226030 x^2 + 299426 x + 170625 \]

which conforms with Gnanadoss [10], to find that if we use \( x = 1.3 \) as an approximation of the dominant root of \( x^2 - x - 1 = 0 \), then a better approximation with the Bernoulli iteration can be given by

\[ \frac{f(49)}{f(48)} = 1.324717973..., \]

which agrees with Hildebrand.

4. GENERALIZED CONTINUED FRACTIONS

Fibonacci numbers have many connections with ordinary continued fractions both pure (complex analysis and number theory) [11,12], and applied (linguistics and numerical analysis) [13]. Here we consider a plausible case for how a generalized continued fraction can be related to arbitrary order sequences. Previous work (for example [14,15]) has tended to focus on going from the continued fraction algorithm to the recurrence relation or difference equation, whereas we are attempting to go in the opposite direction.

From (2) we can write, both formally and more generally, that for \( j = 0, 1, 2 \), \((j = 1 \text{ is the case in (2)})\):

\[ f(3) = x^3 \]

\[ = x + 1 \]
\[ v_{3-j,n} = v_{2-j,n-1} + P_j v_{m-1,2}, \quad n > 0, \]

and

\[ v_{2,n} = v_{1,n-1} + P_1 v_{2,2} \]

so that if we put

\[ a_j^{(n)} = \frac{v_{j-1,n}}{v_{2,n}} \]

then

\[ \frac{v_{2-j,n-1}/v_{2,n}}{v_{2,n+1}/v_{2,n}} = \left( \frac{v_{j,n}/v_{2,n}}{v_{1,n}/v_{2,n}} \right)^{-P_j} \]

and if

\[ b_j^{(n)} = (-1)^j P_j, \]

then

\[ a_{j-1}^{(n+1)} = \frac{a_j^{(n)} - b_j^{(n)}}{a_1^{(n)} - b_1^{(n)}} \]

if we set \( a_0^{(n)} = 1, \forall n. \)

An ordinary periodic continued fraction is an irrational root of a quadratic equation with irrational roots; in particular, the convergents satisfy second order linear recurrence relations with suitable initial conditions with the \( n^{\text{th}} \) convergent

\[ \frac{p}{q} = \frac{x_{n+2}^{-1} - x_{n+1}^{-1}}{x_n^{-1} - x_{n+1}^{-1}} \]

where

\[ p_{n+1} = u_n p_n + p_{n-1}, \]

and

\[ q_{n+1} = a_n q_n + q_{n-1}, \]

For \( k \) a non-negative integer and \( a_{j}^{(k)} \in R, i = 1, 2, \ldots, n-1, \) let [16]

\[ a^{(k)} = [a_1^{(k)}, a_2^{(k)}, \ldots, a_{n-1}^{(k)}] = a^{(k)} \in E_{n-1} \]

and let

\[ f(a^{(k)}) = [b_1^{(k)}, b_2^{(k)}, \ldots, b_{n-1}^{(k)}] = b^{(k)} \in E_{n-1} \]

with \( a_1^{(k)} \neq b_1^{(k)} \), so that for \( T : E_{n-1} \rightarrow E_{n-1} \)

\[ a^{(k)}T = (a_1^{(k)} - b_1^{(k)})^{-1}(a_2^{(k)} - b_2^{(k)}, a_3^{(k)} - b_3^{(k)}, \ldots, a_{n}^{(k)} - b_{n}^{(k)}) = a^{(k+1)} \]

which is a Jacobi-Perron Algorithm (JPA) of the vector \( a^{(0)} \) as a sequence \( \{ a^{(k)} \} \) of vectors in \( E_{n-1} \) and Bernstein has demonstrated how this is a generalization of the continued fraction algorithm [16].
5. CONCLUDING SUGGESTIONS

This raises the related question that given the connection between the ordinary continued fraction and the Euclidean Algorithm, can the latter also be generalized along the following lines.

Instead of relating two integers, suppose we connect two pairs of integers \((a,b)\) and \((c,d)\) in steps analogous to the ordinary Euclidean Algorithm.

Suppose \(c > a > b > d\), so that
\[
\begin{align*}
(c, d) &= x_1 (a, b) + (c - x_1 a, -x_1 b + d) \\
(a, b) &= x_2 (c - x_1 a, -x_1 b + d) + (a - x_2 (c - x_1 a), b - x_2 (-x_1 b + d)) \\
& \quad \vdots \\
& = x_n (u, v) + (-b, -a).
\end{align*}
\]

For example, consider the vector pair \((17,1)\) and \((65,0)\):
\[
\begin{align*}
(65,0) &= 3(17,1) + (14,-3) \\
(17,1) &= 1(14,-3) + (3,4) \\
(14,-3) &= 4(3,4) + (2,-19) \\
(3,4) &= 1(2,-19) + (1,23) \\
(2,-19) &= 2(1,23) + (0,-65)
\end{align*}
\]

in which from (6), the partial quotients are
\[x_1 = 3, x_2 = 1, x_3 = 4, x_4 = 1, x_5 = 2.\]

In a sense (7) contains two Euclidean Algorithms, namely
\[
\begin{align*}
65 &= 3 \times 17 + 14 \\
17 &= 1 \times 14 + 3 \\
14 &= 4 \times 3 + 2 \\
3 &= 1 \times 2 + 1 \\
2 &= 2 \times 1 + 0
\end{align*}
\]
and
\[
\begin{align*}
65 &= 2 \times 23 + 19 \\
23 &= 1 \times 19 + 4 \\
19 &= 4 \times 4 + 3 \\
4 &= 1 \times 3 + 1 \\
3 &= 3 \times 1 + 0
\end{align*}
\]

The partial quotients in (8) are the same as those in (9) but in reverse order.

Conjecture: Consider the following equation
\[
t_{m,n}(l) = lp_1 t_{m,n-1} - p_2 t_{m,n-2} - lp_3 t_{m,n-3}, n \geq 3
\]
and consider the initial values as the same. Then it should be possible to obtain new results using complex numbers among the equations in this paper.
