EXPLICIT COLEMAN INTEGRATION FOR CURVES

JENNIFER S. BALAKRISHNAN AND JAN TUITMAN

Abstract. The Coleman integral is a $p$-adic line integral that plays a key role in computing several important invariants in arithmetic geometry. We give an algorithm for explicit Coleman integration on curves, using the algorithms of the second author \cite{Tui16, Tui17} to compute the action of Frobenius on $p$-adic cohomology. We present a collection of examples computed with our implementation.

1. Introduction

In a series of papers in the 1980s, Coleman formulated a $p$-adic theory of line integration on curves and higher-dimensional varieties with good reduction at $p$ and gave numerous applications in arithmetic geometry. This includes the computation of $p$-adic polylogarithms \cite{Col82}, torsion points on Jacobians of curves \cite{Col85b}, rational points on certain curves with small Mordell-Weil rank \cite{Col85a}, $p$-adic heights on curves (joint with Gross) \cite{CG89}, and $p$-adic regulators in $K$-theory (joint with de Shalit) \cite{CaSS88}. In \cite{CaSS88}, Coleman and de Shalit also introduced a theory of iterated $p$-adic integration on curves, which plays an important role in Kim’s nonabelian Chabauty program \cite{Kim09} to compute rational points on curves.

Besser and de Jeu \cite{BDJ08} gave the first algorithm for explicit computation of these integrals—now known as Coleman integrals—in the case of iterated integrals on $\mathbb{P}^1 \setminus \{0, 1, \infty\}$. These integrals compute $p$-adic polylogarithms, which are conjecturally related to special values of $p$-adic $L$-functions. Balakrishnan, Bradshaw and Kedlaya \cite{BBK10} gave an algorithm to compute single Coleman integrals on odd degree models of hyperelliptic curves, which was further generalized to iterated Coleman integrals on arbitrary hyperelliptic curves in \cite{Bal13, Bal15}. These algorithms all rely on an algorithm for computing the action of Frobenius on $p$-adic cohomology to realize Dwork’s principle of analytic continuation along Frobenius. In the case of odd degree hyperelliptic curves, this is achieved by Kedlaya’s algorithm \cite{Ked10}.

Because of all of the applications mentioned above, it is of interest to develop practical algorithms to carry out Coleman integration on any smooth curve. In the present work, we do this by building on work of Tuitman \cite{Tui16, Tui17}, which generalizes Kedlaya’s algorithm to this setting. We give algorithms to compute single Coleman integrals on curves and develop the precision bounds necessary to obtain provably correct results. Moreover, we provide a complete implementation \cite{BT} of our algorithms in the computer algebra system Magma \cite{BCP97} and present a selection of examples, computing torsion points on Jacobians and carrying out the
Chabauty-Coleman method for finding rational points on curves. The case of iterated Coleman integrals will be discussed in a subsequent paper.

The structure of the paper is as follows: First, in Section 2 we recall what we need from the theory of $p$-adic cohomology and the algorithms from [Tui16, Tui17]. In Section 3 we present our algorithms for Coleman integration. Next, in Section 4 we discuss the precision bounds necessary to obtain provably correct results. Finally, in Section 5 we conclude with a collection of examples computed with our implementation [BT].

2. $p$-ADIC COHOMOLOGY

Let $X$ be a nonsingular projective curve of genus $g$ over $\mathbb{Q}$ given by a (possibly singular) plane model $Q(x, y) = 0$ with $Q(x, y) \in \mathbb{Z}[x, y]$ a polynomial that is irreducible and monic in $y$. Let $d_x$ and $d_y$ denote the degrees of the morphisms $x$ and $y$, respectively, from $X$ to the projective line. Note that this corresponds to the degrees of $Q$ in the variables $y$ and $x$, respectively.

Definition 2.1. Let $\Delta(x) \in \mathbb{Z}[x]$ denote the discriminant of $Q$ with respect to the variable $y$. Moreover, define $r(x) \in \mathbb{Z}[x]$ to be the squarefree polynomial with the same zeros as $\Delta(x)$, in other words, $r = \Delta/(\gcd(\Delta, \frac{d_x}{dx}))$.

Definition 2.2. Let $W^0 \in \text{Gl}_{d_x}(\mathbb{Q}[x, 1/r])$ and $W^\infty \in \text{Gl}_{d_x}(\mathbb{Q}[x, 1/x, 1/r])$ denote matrices such that, if we denote

$$b^0_j = \sum_{i=0}^{d_x-1} W^0_{i+1,j+1}y^i$$

and

$$b^\infty_j = \sum_{i=0}^{d_x-1} W^\infty_{i+1,j+1}y^i$$

for all $0 \leq j \leq d_x - 1$, then

1. $[b^0_0, \ldots, b^0_{d_x-1}]$ is an integral basis for $\mathbb{Q}(X)$ over $\mathbb{Q}[x]$,
2. $[b^\infty_0, \ldots, b^\infty_{d_x-1}]$ is an integral basis for $\mathbb{Q}(X)$ over $\mathbb{Q}[1/x]$,

where $\mathbb{Q}(X)$ denotes the function field of $X$. Moreover, let $W \in \text{Gl}_{d_x}(\mathbb{Q}[x, 1/x])$ denote the change of basis matrix $W = (W^0)^{-1}W^\infty$.

There are good algorithms available to compute such matrices, e.g. [Hes02, Bau16].

Definition 2.3. We say that the triple $(Q, W^0, W^\infty)$ has good reduction at a prime number $p$ if the conditions from [Tui17, Assumption 1] are satisfied. These conditions imply that the curve $X$ has good reduction at $p$ but are stronger. Note that any triple $(Q, W^0, W^\infty)$ has good reduction at all but finitely many prime numbers $p$.

From now on we fix a prime $p$ at which $(Q, W^0, W^\infty)$ has good reduction and we let $X^{an}$ denote the rigid analytic space over $\mathbb{Q}_p$ associated to $X$. There is a specialization map from $X^{an}$ to its special fibre $\overline{X}$. The fibres of this map are called residue disks.

Definition 2.4. We say that a point of $X^{an}$ is very infinite if its $x$-coordinate is $\infty$ and very bad if it is either very infinite or its $x$-coordinate is a zero of $r(x)$. From the fact that $(Q, W^0, W^\infty)$ has good reduction at $p$, it follows that a residue disk contains at most one very bad point and that this point is defined over an unramified extension of $\mathbb{Q}_p$. For a very bad point $P$, we will denote the ramification index of the map $x$ by $e_P$. 

We let $U$ denote the complement of the very bad points in $X$.

**Definition 2.5.** We say that a residue disk (as well as any point inside it) is infinite or bad if it contains a very infinite or a very bad point, respectively. A point or residue disk is called finite if it is not infinite and good if it is not bad. Note that all infinite points and infinite residue disks are bad.

**Remark 2.6.** If a point is very bad, this can mean one of three things:

1. $x(P) = \infty$,
2. the fiber of $X$ above $x(P)$ contains a ramification point,
3. the fiber of $X$ above $x(P)$ contains a point mapping to a singularity of the plane model $Q(x, y) = 0$.

**Definition 2.7.** We denote

$$
S = \mathbb{Q}_p(x, 1/r), \quad S^\dagger = \mathbb{Q}_p(x, 1/r)^\dagger, \\
R = \mathbb{Q}_p(x, 1/r, y)/(Q), \quad R^\dagger = \mathbb{Q}_p(x, 1/r, y)^\dagger/(Q).
$$

Here $(\cdot)^\dagger$ denotes the ring of overconvergent functions obtained by weak completion of the corresponding polynomial ring. A Frobenius lift $F_p : R^\dagger \to R^\dagger$ is defined as a continuous ring homomorphism that reduces to the $p$-th power Frobenius map modulo $p$.

**Theorem 2.8.** There exists a Frobenius lift $F_p : R^\dagger \to R^\dagger$ for which $F_p(x) = x^p$.

**Proof.** See [Tui17, Thm. 2.6].

**Definition 2.9.** For a point $P$ on a curve, we let $\text{ord}_P$ denote the corresponding discrete valuation on the function field of the curve. In particular, $\text{ord}_0$ and $\text{ord}_\infty$ are the discrete valuations on the rational function field $\mathbb{Q}(x)$ corresponding to the points $0$ and $\infty$ on $\mathbb{P}_\mathbb{Q}^1$. We extend these definitions to matrices by taking the minimum over their entries.

From the assumption that $(Q, W^0, W^\infty)$ has good reduction at $p$, it follows that the rigid cohomology spaces $H^1_{\text{rig}}(U \otimes \mathbb{Q}_p)$ and $H^1_{\text{rig}}(X \otimes \mathbb{Q}_p)$ are isomorphic to their algebraic de Rham counterparts [BC94].

**Definition 2.10.** Let $[\omega_1, \ldots, \omega_{2g}]$ be $p$-adically integral 1-forms on $U$ such that

1. $\omega_1, \ldots, \omega_g$ form a basis for $H^0(X, \Omega_X^1)$,
2. $\omega_1, \ldots, \omega_{2g}$ form a basis for $H^1_{\text{rig}}(X \otimes \mathbb{Q}_p)$,
3. $\text{ord}_P(\omega_i) \geq -1$ for all $i$ at all finite very bad points $P$,
4. $\text{ord}_P(\omega_i) \geq -1 + (\text{ord}_0(W) + 1)e_p$ for all $i$ at all very infinite points $P$.

In [Tui16, Tui17] it is explained how such 1-forms can be computed. Actually, property (1) is omitted there, but the algorithm can be easily adapted so that (1) is satisfied as well.

**Definition 2.11.** The $p$-th power Frobenius $F_p$ acts on $H^1_{\text{rig}}(X \otimes \mathbb{Q}_p)$, so there exist a matrix $\Phi \in M_{2g \times 2g}(\mathbb{Q}_p)$ and functions $f_1, \ldots, f_{2g} \in R^\dagger$ such that

$$
F_p^*(\omega_i) = df_i + \sum_{j=1}^{2g} \Phi_{ij} \omega_j
$$

for $i = 1, \ldots, 2g$.  

Let us briefly recall from [Tui16, Tui17] how the matrix $\Phi$ and the functions $f_1, \ldots, f_{2g}$ are computed.

**Algorithm 2.12.**

1. **Compute the Frobenius lift.** Determine $F_p$ as in Theorem 2.8, i.e. set $F_p(x) = x^p$ and determine the elements $F_p(1/r) \in S^\dagger$ and $F_p(y) \in R^\dagger$ by Hensel lifting.

2. **Finite pole order reduction.** For $i = 1, \ldots, 2g$, find $f_{i,0} \in R^\dagger$ such that
   
   $$F_p^*(\omega_i) = df_{i,0} + G_i \left( \frac{dx}{r(x)} \right),$$

   where $G_i \in R$ only has poles at very infinite points.

3. **Infinite pole order reduction.** For $i = 1, \ldots, 2g$, find $f_{i,\infty} \in R$ such that
   
   $$F_p^*(\omega_i) = df_{i,0} + df_{i,\infty} + H_i \left( \frac{dx}{r(x)} \right),$$

   where $H_i \in R$ still only has poles at very infinite points $P$ and satisfies
   
   $$\ord_P(H_i) \geq (\ord_P(W) - \deg(r) + 2)e_P$$

   at all these points.

4. **Final reduction.** For $i = 1, \ldots, 2g$, find $f_{i,end} \in R$ such that
   
   $$F_p^*(\omega_i) = df_{i,0} + df_{i,\infty} + df_{i,end} + \sum_{j=1}^{2g} \Phi_{ij} \omega_j,$$

   where $\Phi \in M_{2g \times 2g}(Q_p)$ is the matrix of $F_p^*$ on $H^1_{rig}(U \otimes Q_p)$ with respect to the basis $[\omega_1, \ldots, \omega_{2g}]$.

The matrix $\Phi$ and the functions $f_i = f_{i,0} + f_{i,\infty} + f_{i,end}$ are exactly what we need from [Tui16, Tui17] to compute Coleman integrals.

### 3. Coleman integrals

Our goal is to compute the Coleman integral $\int_P^Q \omega$ of a 1-form $\omega \in \Omega^1(U \otimes Q_p)$ of the second kind between points $P, Q \in X(Q_p)$.

The Coleman integral satisfies several key properties, which we will use throughout our integration algorithms:

**Theorem 3.1** (Coleman, Coleman–de Shalit). Let $\eta, \xi$ be 1-forms on a wide open $V$ of $X^{an}$ and $P, Q, R \in V$. The definite Coleman integral has the following properties:

1. **Linearity:** $\int_P^Q (a\eta + b\xi) = a\int_P^Q \eta + b\int_P^Q \xi$.
2. **Additivity in endpoints:** $\int_P^Q \xi = \int_P^R \xi + \int_R^Q \xi$.
3. **Change of variables:** If $V' \subset X'$ is a wide open subspace of a rigid analytic space $X'$ and $\phi : V \to V'$ a rigid analytic map then $\int_P^Q \phi^* \xi = \int_{\phi(P)}^{\phi(Q)} \xi$.
4. **Fundamental theorem of calculus:** $\int_P^Q df = f(Q) - f(P)$ for $f$ a rigid analytic function on $V$.

**Proof.** [Col85b] for 1-forms of the second kind and [CaSS88] for general 1-forms. □
Let us first explain how we specify a point $P$. Note that giving $(x, y)$-coordinates might not be sufficient even for a finite very bad point, since there may be multiple points on $X$ lying above a singular point $(x, y)$ of the plane model defined by $Q$. However, a point $P$ is determined uniquely by the value of $x$ (1/x if $P$ is infinite) together with the values of the functions $b^0$ ($b^\infty$ if $P$ is infinite). Note that all of these values are $p$-adically integral. In our implementation, we therefore specify a point $P$ by storing three values $(P', x, b, P')$:

1. $P'$: the $x$-coordinate of $P$ (1/x if $x$ is infinite),
2. $x$: the values of the functions $b^0$ ($b^\infty$ if $P$ is infinite),
3. $b$: true or false, depending on whether the point $P$ is infinite or not.

We will often need power series expansions of functions in terms of a local coordinate (i.e., a uniformizing parameter) $t$ at $P$. This local coordinate should not just be a local coordinate at $P$ on $X \otimes \mathbb{Q}_p$, but on the model $\mathcal{X}$ over $\mathbb{Z}_p$ obtained from the triple $(Q, W^0, W^\infty)$ as in [Tui17, Prop. 2.3]. Then it follows that the reduction modulo $p$ of $t$ is a local coordinate at the reduction modulo $p$ of $P$ and that the residue disk at $P$ is given by $|t| < 1$. In a bad residue disk, we will always expand functions at the very bad point. Therefore, in the following proposition, we only consider points that are either good or very bad.

**Proposition 3.2.** Let $P \in X(\mathbb{Q}_p)$ be a point. Assume that $P$ is either good or very bad. As a local coordinate at $P$, we can take

$$t = \begin{cases} 
- x - x(P) & \text{if } e_P = 1 \text{ (or } t = 1/x \text{ if } P \text{ is infinite}), \\
- b_i^0 - b_i^0(P) \text{ for some } i & \text{otherwise (with } b^0 \text{ replaced by } b^\infty \text{ if } P \text{ is infinite}).
\end{cases}$$

**Proof.** By definition $e_P = \text{ord}_p(x - x(P))$ (or $e_P = \text{ord}_p(1/x)$ if $P$ is infinite). So if $e_P = 1$ then $t = (x - x(P))$ (or $t = 1/x$ if $P$ is infinite) is a local coordinate at $P$ on $X \otimes \mathbb{Q}_p$. If $e_P \geq 2$, then at least one of the $b_i^0 - b_i^0(P)$ (with $b^0$ replaced by $b^\infty$ if $P$ is infinite) has to be a local coordinate at $P$ on $X \otimes \mathbb{Q}_p$, since otherwise there would be no functions on $X \otimes \mathbb{Q}_p$ of order 1 at $P$. In both cases, since $(Q, W^0, W^\infty)$ has good reduction at $p$, the divisor defined by $t$ on $\mathcal{X}$ is smooth over $\mathbb{Z}_p$, so that $t$ is also a local coordinate at $P$ in the stronger sense explained above. $\square$

After choosing a local coordinate $t$ at $P$, in our implementation we compute $xt, bt$ where

1. $xt$ is the power series expansion in $t$ of the function $x$ (1/x if $P$ is infinite),
2. $bt$ is the tuple of power series expansions in $t$ of the functions $b^0$ ($b^\infty$ if $P$ is infinite).

Note that all of these power series have $p$-adically integral coefficients. From $xt, bt$ we will be able to determine the power series expansion in $t$ of any function which is regular at $P$.

A 1-form $\omega \in \Omega^1(U \otimes \mathbb{Q}_p)$ is of the form $f dx$ with $f \in R$. We will usually represent it as follows:

$$\omega = \sum_{i=0}^{d_i-1} \sum_{j=0}^{d_j-1} \frac{f_{ij}(x)}{r(x)^j} b^0_i \frac{dx}{r}$$

with $f_{ij} \in \mathbb{Q}_p[x]$ such that $\text{deg}(f_{ij}) < \text{deg}(r(x))$ for all $i, j$, since $\omega$ needs to be in this form to start the cohomological reduction procedures outlined in Section 2.
We begin by describing the computation of tiny integrals.

**Definition 3.3.** A tiny integral $\int_P^Q \omega$ is a Coleman integral with endpoints $P, Q \in X(Q_p)$ that lie in the same residue disk.

**Algorithm 3.4** (Computing the tiny integral $\int_P^Q \omega$).

1. If the residue disk of $P, Q$ is bad, then find the very bad point $P' \in X(Q_p)$, otherwise set $P' = P$.
2. Compute a local coordinate $t$ and the power series expansions $x_t, b_t$ at $P'$.
3. Integrate using $t$ as coordinate:
   $$\int_P^Q \omega = \int_{t(P)}^{t(Q)} \omega(t).$$

   The Laurent series expansion $\omega(t)$ can be determined from $x_t, b_t$. Note that $\omega$ is of the second kind, so the coefficient of $t^{-1}dt$ is zero.

**Remark 3.5.** The calculation of tiny integrals does not require computing the action of Frobenius on the cohomology space $H^1_{\text{rig}}(X \otimes Q_p)$. This can be a useful consistency check for the integration algorithms that follow, which do use the computation of the action of Frobenius.

When $P, Q \in X(Q_p)$ do not lie in the same residue disk, this approach breaks down since the Laurent series expansions do not converge anymore. In this case we will compute the Coleman integrals $\int_P^Q \omega_i$ for $i = 1, \ldots, 2g$ by solving a linear system imposed by the $p$-th power Frobenius map $F_p$. We first assume that the functions $f_1, \ldots, f_{2g}$ from Section 2 converge at $P, Q$. Note that $f_1, \ldots, f_{2g}$ converge at all good points, but only at bad points that are not too close to the corresponding very bad point. This will be made more precise in the next section.

**Algorithm 3.6** (Compute the $\int_P^Q \omega_i$ assuming $f_1, \ldots, f_{2g}$ converge at $P, Q$).

1. Compute the action of Frobenius on $H^1_{\text{rig}}(X \otimes Q_p)$ using Algorithm 2.12 and store $\Phi$ and $f_1, \ldots, f_{2g}$.
2. Determine the tiny integrals $\int_{F_p(P)}^P \omega_i$ and $\int_{F_p(Q)}^Q \omega_i$ for $i = 1, \ldots, 2g$ using Algorithm 3.4.
3. Compute $f_i(P) - f_i(Q)$ for $i = 1, \ldots, 2g$ and use the system of equations
   $$\sum_{j=1}^{2g} (\Phi - I)_{ij} \left( \int_P^Q \omega_j \right) = f_i(P) - f_i(Q) - \int_P^{F_p(P)} \omega_i - \int_{F_p(Q)}^Q \omega_i$$
   to solve for all $\int_P^Q \omega_i$, as in [BBK10, Algorithm 11].

**Remark 3.7.** Note that the matrix $\Phi - I$ is invertible, since the eigenvalues of $\Phi$ are algebraic numbers of complex absolute value $p^{1/2}$.

When $P$ or $Q$ are bad points and $f_1, \ldots, f_{2g}$ do not converge there, the idea is simply to find points $P', Q'$ in the residue disks of $P$ and $Q$ where these functions do converge, compute the integrals between the new points, and correct for the difference with tiny integrals.

**Algorithm 3.8** (Computing the $\int_P^Q \omega_i$ in general).

1. Determine $P', Q'$ in the residue disks of $P, Q$ at which all functions $f_1, \ldots, f_{2g}$ converge.
(2) Compute the tiny integrals \( f^P \omega_1 \) and \( \int_Q \omega_1 \) for \( i = 1, \ldots, 2g \) using Algorithm 3.4.

(3) Determine \( \int_Q \omega_i \) for \( i = 1, \ldots, 2g \) using Algorithm 3.6.

(4) Compute
\[
\int_P^Q \omega_i = \int_P^P \omega_i + \int_P^Q \omega_i + \int_Q^Q \omega_i.
\]

In general we have to take the points \( P', Q' \) to be defined over some (totally ramified) extension \( K \) of \( \mathbb{Q}_p \) to get far enough away from the very bad point in the bad residue disk. We will always take this extension to be of the form \( \mathbb{Q}_p(p^{1/e}) \) for some positive integer \( e \). Note that Algorithms 3.4 and 3.6 can still be applied in this case and that we may take \( P' \in X(\mathbb{Q}_p) \) in Algorithm 3.4. Since computing in extensions is more expensive, integrals involving bad points are usually the hardest to compute.

For more general 1-forms of the second kind \( \omega \in \Omega^1(U \otimes \mathbb{Q}_p) \), we can now compute the Coleman integrals \( \int_P^Q \omega \) as follows from the output of Algorithms 3.6 and 3.8.

**Algorithm 3.9** (Computing \( \int_P^Q \omega \)).

1. Use Steps (2),(3) and (4) of Algorithm 3.12 to find \( f \in R \) and \( c_i \in \mathbb{Q}_p \) for \( i = 1, \ldots, 2g \) such that
\[
\omega = df + \sum_{i=1}^{2g} c_i \omega_i.
\]

2. Compute \( f(Q) - f(P) \) and determine
\[
\int_P^Q \omega = f(Q) - f(P) + \sum_{i=1}^{2g} c_i \int_P^Q \omega_i.
\]

**Remark 3.10.** Note that we are only considering points \( P, Q \) defined over \( \mathbb{Q}_p(p^{1/e}) \) for some positive integer \( e \). It is possible to extend our work to points defined over arbitrary finite extensions of \( \mathbb{Q}_p \) as in [BBK10, Remark 12]. However, we have not attempted to make this practical or implement it yet, so we leave it out of the discussion here.

4. Precision bounds

So far we have not paid any attention to the fact that we can only compute to finite \( p \)-adic and \( t \)-adic precision in our algorithms. By *precision* we will always mean absolute \( p \)-adic precision, i.e., the valuation of the error term. We extend the \( p \)-adic valuation and the notion of precision to all finite extensions of \( \mathbb{Q}_p \), where they will take non-integer values in general.

Let us start with tiny integrals.

**Proposition 4.1.** Let \( e \) be a positive integer and \( P, Q \in X(\mathbb{Q}_p(p^{1/e})) \) two points in the same residue disk accurate to precision \( N \). Let \( t \) be a local coordinate (in
the sense of Proposition [3.3] at the point \( P' \) from Algorithm [3.3]. Suppose that \( \omega = g(t)dt \) is a differential of the second kind with

\[
g(t) = a_{-k}t^{-k} + a_{-k+1}t^{-k+1} + \ldots \in \mathbb{Z}_p[[t]][t^{-1}]
\]

for some positive integer \( k \). If \( g \) is accurate to \( p \)-adic precision \( N \) and truncated modulo \( t^l \), then the tiny integral \( \int_P^Q \omega \) computed as in Algorithm [3.4] is correct to precision \( \min\{\nu_1, \nu_2, \nu_3\} \) where:

\[
\nu_1 = \min_{i \geq l} \{(i+1)/e - [\log_p(i+1)]\},
\nu_2 = \min_{i \leq l-1} \{N + i/e - [\log_p(i+1)]\},
\nu_3 = N - k \max\{\text{ord}_p(t(P)), \text{ord}_p(t(Q))\} - [\log_p(k-1)].
\]

Proof. Recall from Algorithm [3.4] that

\[
\int_P^Q \omega = \int_{t(P)}^{t(Q)} \omega(t) = \sum_{i=-k}^{\infty} \frac{a_i}{i+1} (t(Q)^{i+1} - t(P)^{i+1}).
\]

where \( a_{-1} = 0 \) since \( \omega \) is of the second kind. Since \( P, Q \) both lie in the residue disk given by \(|t| < 1\), we have that \( \text{ord}_p(t(P)), \text{ord}_p(t(Q)) \geq 1/e \).

First, we bound the error introduced by omitting the terms with \( i \geq l \). Note that \( \text{ord}_p(t(P)^{i+1}), \text{ord}_p(t(Q)^{i+1}) \geq (i+1)/e \) and \( \text{ord}_p(i+1) \leq [\log_p(i+1)] \). Therefore, the valuation of this error is at least \( \nu_1 \).

Next, we consider the error coming from terms with \( 0 \leq i \leq l-1 \). Since \( t(P), t(Q) \) are accurate to precision \( N \) and have valuation at least \( 1/e \), we have that \( t(P)^{i+1}, t(Q)^{i+1} \) are correct to precision \( N + i/e \). Therefore, the valuation of this error is at least \( \nu_2 \).

Finally, we bound the error coming from terms with \( -k \leq i \leq -2 \). This time \( t(P)^{i+1}, t(Q)^{i+1} \) are correct to precision at least \( N + i \text{ord}_p(t(P)), N + i \text{ord}_p(t(Q)) \), respectively (since the loss of precision of an inversion is \( 2 \) times the valuation). Therefore, the valuation of the error is at least \( \nu_3 \) this time.

\( \square \)

Remark 4.2. Since we always have that \( \nu_2 \leq N \), there is no point in increasing the \( t \)-adic precision \( l \) further if \( \nu_1 \geq N \) already. Therefore, in our implementation we take \( l \) to be minimal such that \( \nu_1 \geq N \).

To compute integrals that are not tiny, in Algorithm [3.4] we have to evaluate the functions \( f_i = f_{i,0} + f_{i,\infty} + f_{i,\text{end}} \) from Section [2] at the endpoints for \( i = 1, \ldots , 2g \). Evaluating an element of \( R^\dagger \) at a bad point leads to problems with convergence and loss of precision. We first recall from [Tui16, Tui17] what we know about the poles of the functions \( f_{i,0}, f_{i,\infty}, f_{i,\text{end}} \in R^\dagger \).

The only poles of infinite order are those of the \( f_{i,0} \) at the finite very bad points. It follows from [Tui17, Prop. 2.12, Prop. 3.3, Prop. 3.7] that

\[
f_{i,0} = \sum_{j=0}^{d_x-1} \sum_{k=1}^{\infty} \frac{c_{ijk}(x)}{r(x)^k} a_j^0,
\]

for all \( i \), where the \( c_{ijk} \) are elements of \( \mathbb{Q}_p[x] \) of degree smaller than \( \deg(r) \) that satisfy

\[
\text{ord}_p(c_{ijk}) \geq \lfloor k/p \rfloor + 1 - [\log_p(kc_0)].
\]
with \( c_0 = \max\{e_P : P \text{ finite very bad point}\} \).

Similarly, it follows from [Tui17] Prop. 2.12, Prop. 3.4, Thm. 3.6] that
\[
f_{i,\infty} = \sum_{j=0}^{d_x-1} \sum_{k=0}^{\kappa_1} c_{ijk} x^k b_j^0 = \sum_{j=0}^{d_x-1} \sum_{k=\kappa_2}^{\kappa_3} d_{ijk} x^k b_j^\infty
\]  
for all \( i \), where the \( c_{ijk}, d_{ijk} \) are elements of \( \mathbb{Q}_p \) and
\[
\kappa_3 \leq -\min\{p(\text{ord}_0(W) + 1), (\text{ord}_\infty(W^{-1}) + 1)\}.
\]
Note that this determines bounds on \( \kappa_1, \kappa_2 \) as well.

Finally, it follows from [Tui17] Thm. 3.6] that
\[
f_{i,\text{end}} = \sum_{j=0}^{d_x-1} \sum_{k=0}^{\lambda_1} c_{ijk} x^k b_j^0 = \sum_{j=0}^{d_x-1} \sum_{k=\lambda_2}^{\lambda_3} d_{ijk} x^k b_j^\infty
\]  
for all \( i \), where the \( c_{ijk}, d_{ijk} \) are elements of \( \mathbb{Q}_p \) and
\[
\lambda_3 \leq -(\text{ord}_0(W) + 1).
\]
Note that this determines bounds on \( \lambda_1, \lambda_2 \) as well.

**Proposition 4.3.** On a finite bad residue disk, the functions \( f_{i,0} \) converge outside of the closed disk defined by \( \text{ord}_p(r(x)) \geq 1/p \).

**Proof.** This is clear from (1) and (2). \( \square \)

**Remark 4.4.** Let \( t \) denote a local coordinate at the very bad point of a finite bad residue disk. Then we have that \( \text{ord}_p(r(x)) < 1/p \) is equivalent to the condition \( \text{ord}_p(t) < 1/p^\epsilon \). Consequently, for the functions \( f_{i,0} \) to converge at a point \( P' \in X(\mathbb{Q}_p(p^{1/\epsilon})) \) in the residue disk of \( P \), we need to take \( \epsilon > pep \).

When \( f_1, \ldots, f_{2g} \) do converge at a point \( P \), their computed values at this point will suffer some loss of \( p \)-adic precision in general. In the next three propositions we quantify this precision loss for good, finite bad, and infinite points, respectively.

**Proposition 4.5.** Suppose that the functions \( f_{i,0}, f_{i,\infty}, f_{i,\text{end}} \) are accurate to precision \( N \). Moreover, let \( e \) be a positive integer and let \( P \in X(\mathbb{Q}_p(p^{1/\epsilon})) \) be a good point that is accurate to precision \( N \). Then the computed values \( f_i(P) \) are correct to precision \( N \) as well.

**Proof.** Note that a good point is always finite. Since we have that \( \text{ord}_p(x(P)) \geq 0 \) and \( \text{ord}_p(r(x(P))) = 0 \), there is no loss of precision in evaluating (3) and the expressions in the middle of (4) and (5). \( \square \)

**Proposition 4.6.** Suppose that the functions \( f_{i,0}, f_{i,\infty}, f_{i,\text{end}} \) are accurate to precision \( N \). Moreover, let \( e \) be a positive integer and let \( P \in X(\mathbb{Q}_p(p^{1/\epsilon})) \) be a finite bad point that is accurate to precision \( N \). Let \( \epsilon = \text{ord}_p(r(Q)) \) and suppose that \( \epsilon < 1/p \). Define a function \( \pi \) on positive integers by
\[
\pi(k) = \max\{N, \lfloor k/p \rfloor + 1 - \lfloor \log_p(k e_0) \rfloor\},
\]
where \( e_0 = \max\{e_P : P \text{ finite bad point}\} \). Then the computed values \( f_i(P) \) are correct to precision
\[
\min_{k \in \mathbb{N}} \{\pi(k) - k \epsilon\}.
\]
Proof. In this case $\text{ord}_p(x(P)) \geq 0$, but $\text{ord}_p(r(x(P))) = \epsilon$ with $0 < \epsilon < 1/p$. Clearly there is still no loss of precision in evaluating the expressions in the middle of (3) and (4). However for the $f_{i,0}$ there will be loss of precision. After dropping the terms with valuation greater than or equal to $N$ in (1), the coefficient $c_{ijk}$ will be correct to precision $\pi(k)$ for all $k$. Dividing by $r(x(P))^k$ leads to the loss of $k\epsilon$ digits of precision, so the terms corresponding to $k$ will be correct to precision $\pi(k) - k\epsilon$. Taking the minimum over $k$, we obtain the result. □

Proposition 4.8. Suppose that the matrix $\Phi$ is $p$-adically integral and accurate to precision $N$. Moreover, let $e$ be a positive integer and let $P, Q \in X(Q_p(p^{1/e}))$ be points accurate to precision $N$. Suppose that the right hand side of (3) in Algorithm 3.6 is accurate to precision $N' \leq N$ according to Propositions 4.1, 4.5, 4.6, and 4.7. Then the integrals $\int_P^Q \omega_i$ as computed in Algorithm 3.6 are correct to precision

$$N' - \text{ord}_p(\det(\Phi - I)).$$

Proof. This follows since $(\Phi - I)^{-1}$ has valuation at least $-\text{ord}_p(\det(\Phi - I))$ and is correct to precision $N - \text{ord}_p(\det(\Phi - I))$. □

Remark 4.9. If we do not assume that $\Phi$ is $p$-adically integral, then we can show that the integrals $\int_P^Q \omega_i$ as computed in Algorithm 3.6 are correct to precision

$$N' - \text{ord}_p(\det(\Phi - I)) - \delta$$

with $\delta$ defined as in [Tui17, Definition 4.4].
Remark 4.10. To analyze the loss of precision in Algorithm 3.9, we proceed as follows. First, we use [Tui17, Prop. 3.7, Prop. 3.8] to determine the precision to which $f$ and the $c_i$ are correct. Then we proceed as in Propositions 4.5, 4.6, and 4.7 to determine the precision of the computed values of $f(P)$, $f(Q)$ and $\int_P^Q \omega_i$ for $i = 1, \ldots, 2g$. Finally, we determine the precision to which $\int_P^Q \omega$ is correct, taking into account the valuations of the $c_i$ as well.

5. Examples

5.1. An example from the work of Bruin–Poonen–Stoll.

Let $X/\mathbb{Q}$ be the genus 3 curve given by the following plane model:

$$Q(x, y) = y^3 + (-x^2 - 1)y^2 - x^3y + x^3 + 2x^2 + x = 0.$$  

Bruin, Poonen, and Stoll [BPS16, Prop. 12.17] show that, under the assumption of the Generalized Riemann Hypothesis, the Jacobian of $X$ has Mordell-Weil rank 1. (Note that our working plane model is given by taking the equation in [BPS16, §12.9.2], provided by D. Simon, and setting $x := 1, z := x$.)

We have $W^0 = I$, which means that $b^0 = [1, y, y^2]$ is an integral basis for the function field of $X$ over $\mathbb{Q}[x]$. Moreover, we have

$$W^\infty = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1/x^2 & 0 \\ 0 & -1/x & 1/x^3 \end{pmatrix},$$

so that $b^\infty = [1, y/x^2, -y/x + y^2/x^3]$ is an integral basis for the function field of $X$ over $\mathbb{Q}[1/x]$.

We consider the following points on $X$: $P_1 = (0, 0), P_2 = (0, 1), P_3 = (-3, 4), P_4 = (-1, 0), P_5 = (-1, 1)$, as well as three very infinite points: $P_6$ with $b^\infty$-values $[1, 0, 1]$ $P_7$ with $b^\infty$-values $[1, 1, 1]$ and $P_8$ with $b^\infty$-values $[1, 0, 0]$.

In [BPS16, Prop. 12.17], the authors compute $X(\mathbb{Q})$ by using the fact that $[(P_3) - (P_2)]$ is of infinite order in $J(\mathbb{Q})$ and running a 3-adic Chabauty-Coleman argument. In particular, by computing 3-adic tiny integrals between $P_2$ and $P_3$, they produce a two-dimensional subspace of regular 1-forms annihilating rational points on $X$ and use the Coleman integrals of these differentials to show that these eight points are all of the rational points on $X$.

Here we show how to produce a basis for the two-dimensional space of annihilating 1-forms without immediately appealing to tiny integrals. While it is desirable to use tiny integrals whenever possible, some curves do not readily admit points of infinite order in $J(\mathbb{Q})$ that are given as small integral combinations of known rational points that allow a tiny integral computation. Consequently, in such a scenario, some arithmetic in the Jacobian (working in the kernel of reduction) would be needed to reduce the necessary Coleman integral computation to a tiny integral computation. The computation below shows how one might bypass the Jacobian arithmetic by using Coleman integrals that are not necessarily tiny integrals.

We have $r = x(x + 1)(x^8 + 7x^7 + 21x^6 + 31x^5 + 3x^4 - 51x^3 - 69x^2 - 23x + 4)$. Taking $p = 3$ makes all eight points various types of bad:
We use the values of these three integrals (i.e., by computing the kernel of the associated 3 × 1 matrix) to compute that the two differentials

\[\xi_1 = (1 + O(3^9))\omega_1 + O(3^9)\omega_2 + (430 \cdot 3 + O(3^9))\omega_3\]

\[\xi_2 = O(3^9)\omega_1 + (1 + O(3^9))\omega_2 + (569 \cdot 3^2 + O(3^9))\omega_3\]

give a basis for the regular 1-forms annihilating rational points. Indeed, we can numerically see that the values of the two integrals \(\int_{P_1} P_2 \xi_1, \int_{P_1} P_2 \xi_2\) vanish for all \(P = P_3, P_4, \ldots, P_8\). The code for this example along with the complete computation which proves that \(X(\mathbb{Q}) = \{P_1, P_2, P_3, P_4, P_5, P_6, P_7, P_8\}\) can be found in the file ./examples/bps.m in [BT].
5.2. The modular curve $X_0(44)$.

We consider the genus 4 curve $X = X_0(44)$. We work with the plane model found by Yang [Yan06]:

$$Q(x, y) = y^6 + 12x^2y^3 - 14x^2y^2 + (13x^4 + 6x^2)y - (11x^6 + 6x^4 + x^2) = 0.$$  

We have

$$W^0 = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ \frac{1}{2} & 0 & 0 & 0 & 1 \end{bmatrix}.$$  

Indeed, this plane model is singular, as we see $W_0 \neq I$. We have

$$r = x(x^4 + 6x^2 + 1)(45753125x^8 + 8440476x^6 + 1340814x^4 + 69756x^2 + 3125)$$  

and

$$b^0 = \left[1, y, y^2, \frac{y^3}{x}, -10x^4 - (6x^4 - 13x^2)y + (x^4 + 12x^2)y^2 - x^2y^3 + 1, \frac{1}{x^5 + 6x^3 + x}\right].$$  

We have that $(Q, W^0, W^\infty)$ has good reduction at $p = 7$. Let $P_1$ be the (good) point $(1, 1)$. We consider the point $P_2$ which lies over the singularity $x = 0, y = 0$ of the plane model (which is of degree 5 in $y$). As a point on the smooth model, $P_2$ has ramification index equal to 5, the $b^0$ which is a local coordinate at $P_2$ is $y^3/x$, so $b^0 = (1, 0, 0, 0, 0)$. Computing 7-adic integrals gives

$$\left(\int_{P_2} \omega_1, \int_{P_1} \omega_2, \int_{P_1} \omega_3, \int_{P_1} \omega_4\right) = (O(7^9), O(7^9), O(7^9), O(7^9)),$$

which seems to suggest that $[(P_2) - (P_1)]$ is a torsion point in the Jacobian of $X$. A computation in Magma verifies that $15[(P_2) - (P_1)] = 0$. The code for this example can be found in the file ./examples/x0_44.m in [BT].

5.3. A superelliptic genus 4 curve.

We consider the superelliptic genus 4 curve $X/\mathbb{Q}$ given by the plane model

$$Q(x, y) = y^6 - (x^5 - 2x^4 - 2x^3 - 2x^2 - 3x) = 0.$$  

Using the Magma intrinsic RankBounds, which is based on [PS97] and implemented by Creutz, we find that the Mordell-Weil rank of its Jacobian is 1. A search yields the rational points

$$P_1 = (1, -2), P_2 = (0, 0), P_3 = (-1, 0), P_4 = (3, 0), P_5 = \infty.$$  

We have $b^0 = [1, y, y^2]$ and $r = x^5 - 2x^4 - 2x^3 - 2x^2 - 3x$. A basis for the regular 1-forms on $X$ is given by

$$\omega_1 = \frac{ydx}{r}, \quad \omega_2 = \frac{xydx}{r}, \quad \omega_3 = \frac{x^2ydx}{r}, \quad \omega_4 = \frac{y^2dx}{r}.$$  

Now we take $p = 7$ and compute

$$\int_{P_2}^{P_2} \omega_1 = 12586493 \cdot 7 + O(7^{10}).$$
Since this integral does not vanish, \([\{(P_2) - (P_1)\}]\) is non-torsion in the Jacobian.

The space of annihilating regular 1-forms is 3-dimensional, and a basis is given by

\[
\begin{align*}
\xi_1 &= (1 + O(\tau^{10}))\omega_1 + O(\tau^{10})\omega_2 + O(\tau^{10})\omega_3 - (139167240 + O(\tau^{10}))\omega_4 \\
\xi_2 &= O(\tau^{10})\omega_1 + (1 + O(\tau^{10}))\omega_2 + O(\tau^{10})\omega_3 + (93159229 + O(\tau^{10}))\omega_4 \\
\xi_3 &= O(\tau^{10})\omega_1 + O(\tau^{10})\omega_2 + (1 + O(\tau^{10}))\omega_3 + (8834289 + O(\tau^{10}))\omega_4.
\end{align*}
\]

Indeed, we can numerically see that the values of the 3 integrals \(\int_{P_1} P_1 \xi_1, \int_{P_1} P_1 \xi_2, \int_{P_1} P_1 \xi_3\) vanish for \(P = P_3, P_4, P_5\). The code for this example along with the complete computation which proves that \(X(Q) = \{P_1, P_2, P_3, P_4, P_5\}\) can be found in the file \./examples/C35.m in [BT].

Further examples illustrating how to call and use the code are available in the file examples.pdf in [BT].

ACKNOWLEDGEMENTS

We would like to thank Amnon Besser, Netan Dogra, Alan Lauder and Steffen Müller for helpful discussions.
