Harmonic equiangular tight frames comprised of regular simplices

Matthew Fickus, Courtney A. Schmitt

Abstract

An equiangular tight frame (ETF) is a sequence of unit-norm vectors in a Euclidean space whose coherence achieves equality in the Welch bound, and thus yields an optimal packing in a projective space. A regular simplex is a simple type of ETF in which the number of vectors is one more than the dimension of the underlying space. More sophisticated examples include harmonic ETFs which equate to difference sets in finite abelian groups. Recently, it was shown that some harmonic ETFs are comprised of regular simplices. In this paper, we continue the investigation into these special harmonic ETFs. We begin by characterizing when the subspaces that are spanned by the ETF’s regular simplices form an equi-isoclinic tight fusion frame (EITFF), which is a type of optimal packing in a Grassmannian space. We shall see that every difference set that produces an EITFF in this way also yields a complex circulant conference matrix. Next, we consider a subclass of these difference sets that can be factored in terms of a smaller difference set and a relative difference set. It turns out that these relative difference sets lend themselves to a second, related and yet distinct, construction of complex circulant conference matrices. Finally, we provide explicit infinite families of ETFs to which this theory applies.

Keywords: equiangular tight frame, difference set, conference matrix

2010 MSC: 42C15

1. Introduction

Let $\mathbb{H}$ be a $D$-dimensional complex Hilbert space whose inner product is conjugate-linear in its first argument, and let $\mathcal{N}$ be an $N$-element indexing set. The Welch bound \[ N - D \left[ \frac{D}{D(N-1)} \right] \geq \text{coh}(\{\varphi_n\}_{n \in \mathcal{N}}) := \max_{n \neq n'} \frac{|\langle \varphi_n, \varphi_n' \rangle|}{\|\varphi_n\||\varphi_n'||}. \] It is well known [41] that unit norm vectors $\{\varphi_n\}_{n \in \mathcal{N}}$ in $\mathbb{H}$ achieve equality in (1) if and only if they form an equiangular tight frame (ETF) for $\mathbb{H}$, namely when there exists $C > 0$ such that $C\|x\|^2 = \sum_{n \in \mathcal{N}} |\langle \varphi_n, x \rangle|^2$ for all $x \in \mathbb{H}$ (tightness) and $|\langle \varphi_n, \varphi_n' \rangle|$ is constant over all $n \neq n'$ (equiangularity). In particular, the lines spanned by an ETF’s vectors have the property that the minimum angle between any pair of them is as large as possible, and so are an optimal packing of points in projective space. Because of this optimality, ETFs arise in various applications including waveform design for wireless communication [41], compressed sensing [1, 2], quantum information theory [47, 37] and algebraic coding theory [30].
ETFs are tricky to construct [22]. To elaborate, letting “ETF(\(D, N\))” denote an \(N\)-vector ETF for a \(D\)-dimensional space \(\mathbb{H}\), ETF\((D, D)\) and ETF\((D, D+1)\) correspond to orthonormal bases and regular simplices for \(\mathbb{H}\), respectively, and so exist for every \(D\). Apart from these trivial examples, every other known infinite family of ETFs arises from some type of combinatorial design. Real ETFs in particular are equivalent to a subclass of strongly regular graphs [34, 38, 28, 44], and such graphs are well studied [9, 10, 12]. This equivalence has been partially generalized to the complex setting in various ways, including approaches that exploit properties of roots of unity [7, 5], abelian distance-regular covers of complete graphs [13, 20], and association schemes [29]. Infinite families of ETFs whose redundancy \(\frac{N}{D}\) is either nearly or exactly two arise from the related concepts of conference matrices, Hadamard matrices, Paley tournaments and Gauss sums [41, 28, 36, 40]. Other constructions are more flexible, allowing one to prescribe the order of magnitude of \(D\) and \(\frac{N}{D}\) almost independently, including harmonic ETFs and Steiner ETFs. As detailed in the next section, harmonic ETFs are equivalent to difference sets in finite abelian groups [43, 41, 46, 16]. Meanwhile, Steiner ETFs arise from balanced incomplete block designs [25, 24]. This construction has recently been generalized to yield new infinite families of ETFs arising from projective planes that contain hyperovals, Steiner triple systems, and group divisible designs [23, 19, 17].

By construction, a Steiner ETF is comprised of regular simplices in the sense that its vectors can be partitioned into subsequences, each of which is a regular simplex for its span. Every harmonic ETF arising from a McFarland difference set is known to be unitarily equivalent to a Steiner ETF, and so also has this structure [30]. In a recent paper [18], it was shown that other harmonic ETFs, including those arising from the complements of certain Singer and twin prime power difference sets, are comprised of regular simplices despite not being unitarily equivalent to any Steiner ETF. There, it was further shown that when an ETF is comprised of regular simplices, the subspaces spanned by these simplices form a particular type of optimal packing in Grassmannian space known as an equi-chordal tight fusion frame (ECTFF), achieving the simplex bound of [11].

Here, we continue this investigation into harmonic ETFs that are comprised of regular simplices. In the next section, we establish notation and review known concepts that we shall use later on. In Section 3, we better characterize the properties of difference sets that lead to ETFs comprised of regular simplices; see Theorem 3.3. In Theorem 3.5, we then characterize when the subspaces spanned by these simplices form a special type of ECTFF known as an equi-isoclinic tight fusion frame (EITFF). This occurs for some, but not all, of the ETFs considered in [18]. We further show that every difference set that produces an EITFF in this way also yields a complex circulant conference matrix \(C\), namely an \((S+1) \times (S+1)\) circulant matrix whose diagonal entries are zero, whose off-diagonal entries are unimodular and for which \(C^*C = SI\). In Section 4, we refine this analysis further, showing in Theorem 4.2 that a special class of these ETFs arise from difference sets that are a Gordon-Mills-Welch sum of a relative difference set and a smaller difference set. We further show in Theorem 4.4 that these resulting relative difference sets yield collections of regular simplices that are mutually unbiased in the quantum-information-theoretic sense, as well as complex circulant conference matrices in a way that is related to, but distinct from, the method of Section 3. We then show that two known families of difference sets yield ETFs with these extraordinary properties, namely the complements of certain Singer difference sets (Theorem 4.5), and the complements of certain twin prime power difference sets (Theorem 4.6). Overall, these two methods yield \((S+1) \times (S+1)\) circulant conference matrices when either \(S = Q + 1\) where \(Q\) is a prime power or \(S = Q + 2\) where \(Q\) and \(Q + 2\) are twin prime powers with \(Q \equiv 3 \mod 4\).
2. Background

Let $z^*$ be the complex conjugate of $z \in \mathbb{C}$. More generally, let $A^*$ denote the adjoint of an operator $A$ between two complex Hilbert spaces. For any $N$-element indexing set $\mathcal{N}$, let $\langle y_1, y_2 \rangle := \sum_{n \in \mathcal{N}} (y_1(n))^\ast y_2(n)$ be the standard inner product on $\mathbb{C}^N := \{ y : \mathcal{N} \to \mathbb{C} \}$. For any $M$-element indexing set $\mathcal{M}$, we can regard a linear operator from $\mathbb{C}^N$ to $\mathbb{C}^M$ as a matrix whose entries are indexed by $\mathcal{M} \times \mathcal{N}$, namely as a member of $\mathbb{C}^{M \times N} := \{ A : \mathcal{M} \times \mathcal{N} \to \mathbb{C} \}$, a space we equip with the Frobenius (Hilbert-Schmidt) inner product, $\langle A_1, A_2 \rangle_{\text{Fro}} := \text{Tr}(A_1^\ast A_2)$.

The synthesis operator of a sequence of vectors $\{ \varphi_n \}_{n \in \mathbb{N}}$ in Hilbert space $\mathbb{H}$ is $\Phi : \mathbb{C}^N \to \mathbb{H}$, $\Phi y := \sum_{n \in \mathbb{N}} y(n) \varphi_n$. Its adjoint is the analysis operator $\Phi^* : \mathbb{H} \to \mathbb{C}^N$, $(\Phi^* x)(n) = \langle \varphi_n, x \rangle$. In the special case where $\mathbb{H} = \mathbb{C}^M$, $\Phi$ is the $\mathcal{N} \times \mathcal{M}$ matrix whose $n$th column is $\varphi_n$, and $\Phi^*$ is its $\mathcal{M} \times \mathcal{N}$ conjugate-transpose. Composing these operators yields frame operator $\Phi \Phi^* : \mathbb{H} \to \mathbb{H}$, $\Phi \Phi^* x = \sum_{n \in \mathbb{N}} \langle \varphi_n, x \rangle \varphi_n$ and the $\mathcal{N} \times \mathcal{N}$ Gram matrix $\Phi \Phi^* : \mathbb{C}^N \to \mathbb{C}^N$ whose $\langle n, n' \rangle$th entry is $(\Phi^* \Phi)(n, n') = \langle \varphi_n, \varphi_{n'} \rangle$. We sometimes also regard each vector $\varphi_n$ as a degenerate synthesis operator $\varphi_n : \mathbb{C} \to \mathbb{H}$, $\varphi_n(x) = x \varphi_n$, an operator whose adjoint is the linear functional $\varphi_n^* : \mathbb{H} \to \mathbb{C}$, $\varphi_n^* x = \langle \varphi_n, x \rangle$. Under this notation, the frame operator of $\{ \varphi_n \}_{n \in \mathbb{N}}$ is $\Phi \Phi^* = \sum_{n \in \mathbb{N}} \varphi_n \varphi_n^*$.

We say that $\{ \varphi_n \}_{n \in \mathbb{N}}$ is a $(C, \varepsilon)$-tight frame for $\mathbb{H}$ when $\Phi \Phi^* = C I$ for some $C > 0$. In this case, when the vectors $\{ \varphi_n \}_{n \in \mathbb{N}}$ are regarded as members of some (larger) Hilbert space $\mathbb{K}$ which contains $\mathbb{H} = \text{span}\{ \varphi_n \}_{n \in \mathbb{N}}$ as a (proper) subspace, we say that $\{ \varphi_n \}_{n \in \mathbb{N}}$ is a tight frame for its span; elsewhere in the literature, such sequences are sometimes called “tight frame sequences.” Here the analysis operator $\Phi^* : \mathbb{H} \to \mathbb{C}^N$ extends to an operator $\Phi^* : \mathbb{K} \to \mathbb{C}^N$ and $\{ \varphi_n \}_{n \in \mathbb{N}}$ is a tight frame for its span precisely when $\Phi \Phi^* x = C x$ for all $x \in \mathbb{K} = \text{span}\{ \varphi_n \}_{n \in \mathbb{N}} = C(\Phi)$. As shown in [23], this is equivalent to having either $\Phi \Phi^* = C I$, $(\Phi^* \Phi)^2 = C \Phi \Phi^*$ or $(\Phi^* \Phi)^2 = C \Phi^* \Phi$. In particular, $\{ \varphi_n \}_{n \in \mathbb{N}}$ is a $C$-tight frame for some $D$-dimensional space if and only if its Gram matrix $\Phi \Phi^*$ has eigenvalues $C$ and $0$ with multiplicity $\mathcal{N} - D$ and $D$, respectively.

A Naimark complement of an $N$-vector $C$-tight frame $\{ \varphi_n \}_{n \in \mathbb{N}}$ for a $D$-dimensional space $\mathbb{H}$ is any sequence $\{ \psi_n \}_{n \in \mathbb{N}}$ of vectors in some space $\mathbb{K}$ such that $\Phi \Phi^* + \Psi \Psi^* = C I$. Since $\Phi \Phi^*$ has eigenvalues $C$ and 0 with multiplicity $\mathcal{N} - D$ and $D$, respectively, $\{ \psi_n \}_{n \in \mathbb{N}}$ is a $C$-tight frame for its $(\mathcal{N} - D)$-dimensional span. Being defined in terms of Gram matrices, Naimark complements are unique up to unitary transformations. They exist whenever $\mathcal{N} - D$; one way to construct one is to regard $\mathbb{H}$ as $\mathbb{C}^D$, and take $\{ \psi_n \}_{n \in \mathcal{N}}$ to be the columns of the $(\mathcal{N} - D) \times \mathcal{N}$ matrix $\Psi$ whose rows, when taken together with the rows of $\Phi$, form an equal-norm orthogonal basis for $\mathbb{C}^N$.

2.1. Equi-chordal and equi-isoclinic tight fusion frames

When $\{ \varphi_n \}_{n \in \mathbb{N}}$ is a sequence of unit norm vectors, its frame operator $\Phi \Phi^* = \sum_{n \in \mathbb{N}} \varphi_n \varphi_n^*$ is the sum of the orthogonal projection operators onto their 1-dimensional spans. More generally, if $\{ \mathcal{U}_n \}_{n \in \mathbb{N}}$ is any sequence of $M$-dimensional subspaces of $\mathbb{H}$, its fusion frame operator is the sum of the corresponding orthogonal projection operators $\{ \mathcal{P}_n \}_{n \in \mathbb{N}}$. In particular, $\{ \mathcal{U}_n \}_{n \in \mathbb{N}}$ is a tight fusion frame (TFF) for $\mathbb{H}$ if there exists $C > 0$ such that $C I = \sum_{n \in \mathcal{N}} \mathcal{P}_n$. Here, the tight fusion frame constant is necessarily $C = \frac{MN}{D}$ since $CD = \text{Tr}(C I) = \sum_{n \in \mathcal{N}} \text{Tr}(\mathcal{P}_n) = MN$. As such, any sequence $\{ \mathcal{U}_n \}_{n \in \mathcal{N}}$ of $M$-dimensional subspaces of $\mathbb{H}$ satisfies

$$0 \leq \left\| \sum_{n \in \mathcal{N}} \mathcal{P}_n - \frac{MN}{D} I \right\|_{\text{Fro}}^2 = \sum_{n \in \mathcal{N}} \sum_{n' \in \mathcal{N}} \langle \mathcal{P}_n, \mathcal{P}_{n'} \rangle_{\text{Fro}} - \frac{M^2 N^2}{D} = \sum_{n \in \mathcal{N}} \sum_{n' \neq n} \text{Tr}(\mathcal{P}_n \mathcal{P}_{n'}) - \frac{M N (M N - D)}{D},$$

and achieves equality in this bound if and only if $\{ \mathcal{U}_n \}_{n \in \mathbb{N}}$ is a TFF for $\mathbb{H}$. At the same time, any such $\{ \mathcal{U}_n \}_{n \in \mathcal{N}}$ also satisfies $\sum_{n \in \mathcal{N}} \sum_{n' \neq n} \text{Tr}(\mathcal{P}_n \mathcal{P}_{n'}) \leq N (N - 1) \max_{n \neq n'} \text{Tr}(\mathcal{P}_n \mathcal{P}_{n'})$, and achieves
equality in this bound if and only if it is equi-chordal, namely when the (squared) chordal distance \( \text{dist}^2_c(U_n, U_{n'}) := \frac{1}{2} ||P_n - P_{n'}||_2^2 = M - \text{Tr}(P_n P_{n'}) \) between any pair of subspaces is the same. Combining these two inequalities gives that any such \( \{U_n\}_{n \in \mathbb{N}} \) satisfies

\[
\frac{M(N-D)}{D(N-1)} \leq \max_{n \neq n'} \text{Tr}(P_n P_{n'}) = M - \min_{n \neq n'} \text{dist}^2_c(U_n, U_{n'}),
\]

and achieves equality in this bound if and only if it is a TFF for \( \mathbb{H} \) that is also equi-chordal, namely an ECTFF for \( \mathbb{H} \). When rewritten as \( \min_{n \neq n'} \text{dist}^2_c(U_n, U_{n'}) \leq \frac{M(N-D)N}{D(N-1)} \), namely as the simplex bound of [11], we see that an ECTFF \( \{U_n\}_{n \in \mathbb{N}} \) has the property that the minimum chordal distance between any pair of these subspaces is as large as possible. In particular, with respect to the chordal distance, an ECTFF is an optimal packing in the Grassmannian space that consists of all M-dimensional subspaces of \( \mathbb{H} \).

Continuing, for any given sequence \( \{U_n\}_{n \in \mathbb{N}} \) of M-dimensional subspaces of \( \mathbb{H} \), we each for \( n \in \mathbb{N} \) let \( E_n \) be the synthesis operator of an orthonormal basis \( \{e_{n,m}\}_{m \in \mathbb{M}} \) for \( U_n \), and so \( E_n^*E_n = I \) and \( P_n = E_n E_n^* \). Here, since \( \sum_{n \in \mathbb{N}} P_n = \sum_{n \in \mathbb{N}} E_n E_n^* = \sum_{n \in \mathbb{N}} \sum_{m \in \mathbb{M}} e_{n,m} e_{n,m}^* \), we have that \( \{U_n\}_{n \in \mathbb{N}} \) is a TFF for \( \mathbb{H} \) if and only if the concatenation (union) \( \{e_{n,m}\}_{n \in \mathbb{N}, m \in \mathbb{M}} \) of these bases is a tight frame for \( \mathbb{H} \). Moreover, \( \text{Tr}(P_n P_{n'}) = \text{Tr}(E_n E_{n'}^*) = ||E_n E_{n'}^*||_F^2 = ||E_n E_{n'}^*||_F^2 \leq \sum_{m=1}^M \sigma_{n,n',m}^2 \) where \( \sigma_{n,n',m} \) are the singular values of the \( M \times M \) cross-Gram matrix \( E_n E_{n'}^* \), arranged without loss of generality in decreasing order. Here, since the induced 2-norm of such a cross-Gram matrix satisfies \( \sigma_{n,n',1} = ||E_n E_{n'}^*||_F \leq ||E_n||_F ||E_{n'}||_F = 1 \), there exists an increasing sequence \( \{\theta_{n,n',m}\}_{m=1}^M \) in \([0, \frac{\pi}{2}]\) such that \( \sigma_{n,n',m} = \cos(\theta_{n,n',m}) \). These principal angles determine the chordal distances between subspaces: \( \text{dist}^2_c(U_n, U_{n'}) = M - \text{Tr}(P_n P_{n'}) = M - \sum_{m=1}^M \cos^2(\theta_{n,n',m}) = \sum_{m=1}^M \sin^2(\theta_{n,n',m}). \)

An EITFF is a special type of ECTFF whose principal angles are constant. To elaborate, \( \text{Tr}(P_n P_{n'}) = \sum_{m=1}^M \cos^2(\theta_{n,n',m}) \leq M \cos^2(\theta_{n,n',1}) = M ||E_n E_{n'}^*||_F^2 \) for any \( n \neq n' \). Moreover, \( U_n \) and \( U_{n'} \) achieve equality here if and only if they are isoclinic in the sense that \( \{\theta_{n,n',m}\}_{m=1}^M \) is constant over \( m \). This happens precisely when, for some \( \sigma_{n,n'} \geq 0 \), we have \( E_n^* E_{n'} E_{n'}^* = \sigma_{n,n'}^2 I \), or equivalently that \( P_n P_{n'} P_n = \sigma_{n,n'}^2 P_n \). When combined with [2], these facts imply

\[
\frac{MN-D}{D(N-1)} \leq \frac{1}{M} \max_{n \neq n'} \text{Tr}(P_n P_{n'}) \leq \max_{n \neq n'} ||E_n^* E_{n'}||_F^2 = 1 - \min_{n \neq n'} \text{dist}^2_c(U_n, U_{n'}),
\]

where \( \text{dist}^2_c(U_n, U_{n'}) := 1 - ||E_n^* E_{n'}||_F^2 = \sin^2(\theta_{n,n',1}) \) is the (squared) spectral distance between \( U_n \) and \( U_{n'} \). Moreover, \( \{U_n\}_{n \in \mathbb{N}} \) achieves equality throughout [3] if and only if it is an ECTFF for \( \mathbb{H} \) where each pair of subspaces is isoclinic, or equivalently, a TFF for \( \mathbb{H} \) that is equi-isoclinic in the sense that \( \theta_{n,n',m} \) is constant over all \( n \neq n' \) and \( m \), namely when there is some \( \sigma \geq 0 \) such that \( P_n P_{n'} P_n = \sigma_{n,n'}^2 P_n \) for all \( n \neq n' \). In particular, every EITFF is an optimal packing in Grassmannian space with respect to both the chordal distance and the spectral distance.

In the special case where \( M = 1 \), we can let \( E_n = \varphi_n \) be any unit vector in the line \( U_n \), both [2] and [3] reduce to the Welch bound [11], and \( \{\varphi_n\}_{n \in \mathbb{N}} \) achieves equality in this bound if and only if it is a tight frame for \( \mathbb{H} \) that is also equiangular, namely an ETF for \( \mathbb{H} \). An ETF(\( D, D \)) equates to \( D \) orthonormal vectors. When, \( D < N \), any ETF(\( D, N \)) \( \{\varphi_n\}_{n \in \mathbb{N}} \) has a Naimark complement \( \{\psi_n\}_{n \in \mathbb{N}} \) which itself is tight and satisfies \( \Psi^* \Psi = CI - \Phi^* \Phi \), and so normalizing these vectors yields an ETF(\( N - D, N \)). In particular, an ETF(\( S, S + 1 \)) exists for any positive integer \( S \), being equivalent to a Naimark complement of an ETF(\( 1, S + 1 \), namely to a sequence of \( S + 1 \) unimodular scalars. We refer to any ETF(\( S, S + 1 \)) as a regular S-simplex. In light of the Welch bound [11], any \( S + 1 \) linearly dependent unit vectors with coherence \( \frac{1}{\sqrt{S + 1}} \) necessarily form a regular simplex for their span.
ECTFFs and EITFFs that consist of subspaces of dimension $M \geq 2$ have received some attention in the literature \cite{33, 27, 32, 34}, but not nearly as much as ETFs. EITFFs seem particularly difficult to construct. In fact, essentially only three constructions of them are known. The first method is to take a Naimark complement of the tight frame formed by concatenating any orthonormal bases for the subspaces that comprise a given EITFF; doing so converts an EITFF for a $D$-dimensional space that consists of $N$ subspaces of dimension $M$ into an EITFF for an $(MN - D)$-dimensional space that consists of $N$ subspaces of dimension $M$. The second known method is to replace each entry of the synthesis operator $\Phi$ of a complex ETF($D, N$) with its $2 \times 2$ representation as an operator from $\mathbb{R}^2 \rightarrow \mathbb{R}^2$, namely to apply the one-to-one ring homomorphism $z = x + iy \mapsto \begin{bmatrix} x & -y \\ y & x \end{bmatrix}$ to every entry of $\Phi$; the resulting pairs of columns form orthonormal bases for $N$ subspaces of $\mathbb{R}^{2D}$, each of dimension $M = 2$, that form an EITFF \cite{27}.

The third known method for constructing EITFFs harks back to \cite{33}: if $\{\delta_m\}_{m \in M}$ is any orthonormal basis for an $M$-dimensional space $\mathbb{H}$, and for each $m \in M$, $\{\varphi_n^{(m)}\}_{n \in N}$ is any ETF($D, N$) for $\mathbb{K}$, then the subspaces $\{U_n\}_{n \in N}$, $U_n := \text{span}\{\delta_m \circ \varphi_n^{(m)}\}_{m \in M}$ form an EITFF for the $MD$-dimensional space $\mathbb{K} \otimes \mathbb{H}$ that consists of $N$ subspaces of dimension $M$. Indeed, since $\langle \delta_m \circ \varphi_n^{(m)}, \delta_{m'} \circ \varphi_{n'}^{(m')} \rangle = \delta_m \langle \varphi_n^{(m)}, \varphi_{n'}^{(m')} \rangle$, the subspaces $\{\delta_m \circ \varphi_n^{(m)}\}_{m \in M}$ is an orthonormal basis for $U_n$, and moreover for any $n \neq n'$, the corresponding cross-Gram matrix $E_n E_{n'}$ is diagonal with diagonal entries of modulus $\frac{N - D}{2}$. As such, $\{U_n\}_{n \in N}$ achieves equality in \cite{3} where “$D$” is $MD$. The lack of other constructions of EITFFs leads to the following conjecture \cite{21}:

**Conjecture 2.1.** If $N$ spaces of dimension $M$ form an EITFF for a $D$-dimensional Hilbert space, then $M$ divides $D$ and there exists an $N$-vector ETF for a Hilbert space of dimension $D^2$.

### 2.2. Harmonic equiangular tight frames and difference sets

A **character** on a finite abelian group $G$ is a homomorphism $\gamma : G \rightarrow T = \{z \in \mathbb{C} : |z| = 1\}$. The (**Pontryagin**) dual of $G$ is the set $\hat{G}$ of all characters of $G$, and is itself a group under pointwise multiplication. In the general setting, we shall denote the group operations on $G$ and $\hat{G}$ as addition and multiplication, respectively. It is well known that since $G$ is finite, $\hat{G}$ is isomorphic to $G$, and moreover that $\{\gamma : \gamma \in \hat{G}\}$ is an equal-norm orthogonal basis for $\mathbb{C}^G$, meaning its synthesis operator $F : \mathbb{C}^\hat{G} \rightarrow \mathbb{C}^G$ is invertible with $F^{-1} = \frac{1}{|G|} F^*$ where $G$ is the order of $G$. This operator is usually regarded as the $(G \times \hat{G})$-indexed character table of $G$ whose $(g, \gamma)$th entry is $F(g, \gamma) = \gamma(g)$.

Its adjoint is the **discrete Fourier transform** (DFT) on $G$, $(F^*x)(\gamma) = \langle \gamma, x \rangle$. Since $FF^* = GI$, the rows of $F$ are equal-norm orthogonal. Of course, any subset of these rows also has this property: if $D$ is any nonempty $D$-element subset of $G$, then letting $\Phi$ be the $(D \times \hat{G})$-index defined by $\Phi(d, \gamma) = \frac{1}{\sqrt{|G|}} \gamma(d)$, we have $\Phi \Phi^* = \frac{1}{|G|} I$. Regarding the $\gamma$th column of $\Phi$ as the unit norm vector $\varphi_\gamma = \frac{1}{\sqrt{|G|}} \gamma \in \mathbb{C}^D$, we equivalently have that $\{\varphi_\gamma : \gamma \in \hat{G}\}$ is a tight frame for $\mathbb{C}^D$. Such tight frames are dubbed **harmonic frames**, and have a circulant Gram matrix with $\langle \varphi_\gamma, \varphi_{\gamma'} \rangle = \frac{1}{|G|} \sum_{d \in D} (\gamma^{-1}(\gamma')(d))$ where $\chi_D$ is the characteristic function of $D$.

The convolution of $x_1, x_2 \in \mathbb{C}^\hat{G}$ is $x_1 \ast x_2 \in \mathbb{C}^\hat{G}$, $(x_1 \ast x_2)(\gamma) := \sum_{\gamma' \in \hat{G}} x_1(\gamma') x_2(\gamma - \gamma')$, and satisfies $F^*(x_1 \ast x_2)(\gamma) = (F^*x_1)(\gamma)(F^*x_2)(\gamma)$ for all $\gamma \in \hat{G}$. Meanwhile, the Fourier transform of the **involution** $\hat{x}(g) := [x(-g)]^*$ of $x \in \mathbb{C}^\hat{G}$ is the pointwise complex conjugate of $F^* \hat{x}$. In particular, $|F^*(x_D \ast \hat{x_D})(\gamma)| = |\langle F^* \chi_D, \hat{x_D} \rangle(\gamma)\rangle|^2$ for all $\gamma \in \hat{G}$ where, for any $g \in G$,

$$\langle \chi_D \ast \hat{x_D}, (g') \rangle = \sum_{g \in D} \chi_D(g') \chi_D(g' - g) = #([D \cap (g + D)] = #\{(d, d') \in D \times D : g = d - d'\}$$
is the number of times $g$ can be written as a difference of members of $D$.

Now let $H$ be any subgroup of $G$ of order $H$. The Poisson summation formula states that $F^* \chi_H = \mathcal{H} \chi_H^{-1}$ where $\mathcal{H} : = \{ \gamma \in \mathcal{G} : \gamma(h) = 1, \forall h \in H \}$ is the annihilator of $H$. It is well known that $\mathcal{H}^{-1}$ is a subgroup of $\mathcal{G}$, and that $\mathcal{H}^{-1}$ is isomorphic to the dual of $G/H$, via the identification of $\gamma \in \mathcal{H}$ with the mapping $\psi \mapsto \gamma(\psi)$; here and throughout, we denote the cosets $g + H$ and $\gamma H$ as simply $g$ and $\gamma$, respectively. In particular, $\mathcal{H}$ has order $\frac{G}{H}$. A subset $D$ of $\mathcal{G}$ is an $H$-relative difference set (RDS) of $G$ if every $g \notin H$ can be written as a difference of members of $D$ the same number of times, while no nonzero member of the “forbidden subgroup” $H$ can be written in this way, namely if and only if there exists a scalar $\Lambda$ such that $\chi_D * \chi_D = D \delta_0 + \Lambda(1 - \chi_H)$, where $1 = \chi_G$ is the all-ones vector. Taking Fourier transforms, this equates to having

$$|F^* \chi_D|^2 = F^*[D \delta_0 + \Lambda(1 - \chi_H)] = D1 + \Lambda(G \delta_1 - H \chi_{H^{-1}}).$$

In particular, we necessarily have $D^2 = |(F^* \chi_D)(1)|^2 = D + \Lambda(G - H)$, that is, $\Lambda = \frac{D(D-1)}{G-1}$; alternatively, this follows from the fact that each of the $G - H$ members of $H^c$ appears the same number of times in the difference table of $D$, namely the $(D \times D)$-indexed matrix whose $(d, d')$th entry is $d - d'$. As such, under this assumption, we have that $D$ is an $H$-RDS if and only if

$$|(F^* \chi_D)(\gamma)|^2 = \begin{cases} D - \Lambda H, & \gamma \in \mathcal{H}^{-1}, \gamma \neq 1, \\ D, & \gamma \notin \mathcal{H}^{-1}, \end{cases} \quad \Lambda = \frac{D(D-1)}{G-1},$$

namely if and only if the corresponding harmonic tight frame $\{\varphi_\gamma\}_{\gamma \in \mathcal{G}}$ satisfies

$$|\langle \varphi_\gamma, \varphi_{\gamma'} \rangle| = \frac{1}{D} \begin{cases} \sqrt{D - \Lambda H}, & \gamma = \gamma', \gamma \neq 1, \\ \sqrt{D}, & \gamma \neq \gamma', \end{cases} \quad \Lambda = \frac{D(D-1)}{G-1}.$$

Following the literature [35], we denote such a set $D$ as an RDS($G/H, D, \Lambda$).

In the particular case where $H = \{0\}$, a relative difference set is simply called a difference set. Here, every $g \neq 0$ can be written as a difference of members of $D$ in exactly $\Lambda = \frac{D(D-1)}{G-1}$ ways. Moreover, since $\{0\}^{-1} = G$ and

$$D - \Lambda H = D - \frac{D(D-1)}{G-1} = \frac{D(G-D)}{G-1} = \frac{D^2}{G-1}, \quad S := \left\lfloor \frac{D(G-D)}{G-1} \right\rfloor,$$

we see that (4) and (5) reduce to having

$$|F^* \chi_D(\gamma)|^2 = \frac{D^2}{G-1}, \forall \gamma \neq 1, \quad \text{i.e.,} \quad |\langle \varphi_\gamma, \varphi_{\gamma'} \rangle| = \frac{1}{D}, \forall \gamma \neq \gamma'.$$

Since $\frac{1}{D}$ also happens to be the Welch bound for $G$ vectors in a $D$-dimensional space, we obtain that $D$ is a difference set for $G$ if and only if $\{\varphi_\gamma\}_{\gamma \in \mathcal{G}}$ is an ETF for $C^D$. When $D$ is a difference set, the quantity $D - \Lambda = \frac{D^2}{G-1}$ is known as the order of $D$. The complement $D^c$ of any difference set $D$ for $G$ is another difference set for $G$ of the same order, and the resulting harmonic ETFs are Naimark complementary. It is also straightforward to verify that shifting or applying a group automorphism of $G$ to a difference set $D$ of $G$ yields another difference set for $G$.

When $D$ is an $H$-RDS for $G$, then for any subgroup $K$ of $H$ of order $K$, applying the quotient map $g \mapsto g + K$ to $D$ produces an $(H/K)$-RDS for $G/K$, transforming an RDS($G/H, D, \Lambda$) into an RDS($G/H, K, D, K\Lambda$). Indeed, $(d + K) - (d' + K) = g + K$ if and only if $d - d' = g + k$ for some $k \in K$. For $g \in K$, this occurs exactly $D$ times, namely when $k = -g$, $d \in D$ is arbitrary and $d' = -d$. Meanwhile, for $g \notin H$, this occurs exactly $K\Lambda$ times, namely $\Lambda$ times for each $k \in K$. Finally, for $g \in H \setminus K$, no such $(d, d')$ exist, regardless of the value of $k$. In particular, quotienting an $H$-RDS $D$ by $H$ produces a $D$-element difference set $\overline{D} = \{\overline{g} : g \in D\}$ for $G/H$, transforming an RDS($G/H, D, \Lambda$) into an RDS ($G/1, D, H\Lambda$).
3. Equi-isoclinic subspaces arising from harmonic ETFs

3.1. Fine difference sets

It was recently shown that certain harmonic ETFs are comprised of regular simplices \cite{18}. To see this from basic principles, let \( D \) be a \( D \)-element difference set in an abelian group \( G \) of order \( G \), let \( \{ \varphi_{\gamma} \}_{\gamma \in G} \) be the corresponding harmonic ETF for \( \mathbb{C}^D \), and let \( S = \frac{D(G-1)}{G-D} \) be the reciprocal of the corresponding Welch bound. If \( S \) is an integer, then any subsequence \( \{ \varphi_{\gamma} \}_{\gamma \in S} \) of \( \{ \varphi_{\gamma} \}_{\gamma \in G} \) that consists of \( S + 1 \) linearly dependent vectors is a regular simplex for its span: being linearly dependent, \( \{ \varphi_{\gamma} \}_{\gamma \in S} \) is contained in some \( S \)-dimensional subspace \( U \) of \( \mathbb{C}^D \); at the same time, the coherence of \( \{ \varphi_{\gamma} \}_{\gamma \in S} \) is \( \frac{1}{S} \), meaning it achieves the Welch bound for any \( S + 1 \) vectors in \( U \), and thus is an ETF(\( S, S + 1 \)) for \( U \). Moreover, if \( D \) is disjoint from a subgroup \( H \) of \( G \), then the vectors indexed by any coset of its annihilator \( H^\perp \) are trivially dependent, since they sum to zero: for any \( \gamma \in G \) and \( d \in D \), the Poisson summation formula gives

\[
\sum_{\gamma' \in H^\perp} \varphi_{\gamma'}(d) = \sum_{\gamma' \in H^\perp} \frac{1}{\sqrt{G}}(\gamma')(d) = \frac{1}{\sqrt{G}}(d)(\Phi_{H^\perp})(d) = \frac{1}{\sqrt{G}}(d)(\Phi_{H^\perp})(d) = 0.
\]

Altogether, we see that every subsequence \( \{ \varphi_{\gamma'} \}_{\gamma' \in H^\perp} \) of the ETF \( \{ \varphi_{\gamma} \}_{\gamma \in G} \) is a regular simplex provided the underlying difference set \( D \) is disjoint from a subgroup \( H \) of order \( H = \frac{G}{S+1} \), that is, whose annihilator \( H^\perp \) has order \( S + 1 \). In \cite{18}, it was further shown that several known families of difference sets have this property. To make these concepts easier to discuss moving forward, we now give this property a name:

**Definition 3.1.** A \( D \)-element difference set \( D \) for an abelian group \( G \) of order \( G \) is *fine* if there exists a subgroup \( H \) of \( G \) that is disjoint from \( D \) and of order \( H = \frac{G}{S+1} \), where \( S = \frac{D(G-1)}{G-D} \).

When this occurs with a specific \( H \), we say \( D \) is \( H \)-fine.

Below we show that such difference sets \( D \) are “fine” in the sense that they can “pass through a fine sieve,” that is, are disjoint from a subgroup \( H \) of \( G \) that is as large as any such subgroup can be. We further show that when a difference set is fine, every nonidentity coset of the corresponding subgroup \( H \) intersects \( D \) in the same number of points. Here, it helps to introduce the following notation: if \( H \) is any subgroup of a finite abelian group \( G \), and \( D \) is any subset of \( G \), let

\[
D_g := H \cap (D - g), \quad \forall g \in G.
\]

**Example 3.2.** As a simple example of a complement of a Singer difference set, let \( G \) be the cyclic group \( \mathbb{Z}_{15} \) and let \( D \) be \{6, 11, 7, 12, 13, 3, 9, 14\}; the rationale behind this unusual ordering of the elements of \( D \) will eventually become apparent. Computing the difference table of \( D \), we see that each of the 14 nonzero elements of \( G \) can be written as a difference of members of \( D \) in exactly \( \Lambda = \frac{D(G-1)}{G-1} = \frac{8(7)}{14} = 4 \) ways:

| - | 6 11 7 12 13 3 9 14 |
|---|---|---|---|---|---|---|---|
| 6 | 0 10 14 9 8 3 12 7 |
| 11 | 5 0 4 14 13 8 2 12 |
| 7 | 1 11 0 10 9 4 13 8 |
| 12 | 6 1 5 0 14 9 3 13 |
| 13 | 7 2 6 1 0 10 4 14 |
| 3 | 12 7 11 6 5 0 9 4 |
| 9 | 3 13 2 12 11 6 0 10 |
| 14 | 8 3 7 2 1 11 5 0 |
Thus, $\mathcal{D}$ is a difference set for $\mathcal{G}$. Here, $S = \lfloor \frac{D(G-1)}{G} \rfloor = \lfloor \frac{8(14)}{15} \rfloor = 4$ is an integer. Moreover, $S+1 = 5$ divides $G = 15$, and so the cyclic group $\mathcal{G}$ contains a unique subgroup of order $H = \frac{G}{S+1} = 3$, namely $\mathcal{H} = \{0, 5, 10\}$. Being disjoint from $\mathcal{H}$, we see that $\mathcal{D}$ is fine in the sense of Definition 3.1. Moreover, since the cosets of $\mathcal{H}$ partition $\mathcal{G}$, we can partition $\mathcal{D}$ into its intersections with these cosets, namely according to congruence modulo 5:

$$\mathcal{D} = \{6, 11, 7, 12, 13, 3, 9, 14\} = \emptyset \sqcup \{6, 11\} \sqcup \{7, 12\} \sqcup \{13, 3\} \sqcup \{9, 14\}.$$

Here, we note that every nontrivial member of this partition has cardinality $\frac{D}{S} = \frac{8}{4} = 2$. Below, we show this is not a coincidence, showing that this property is equivalent to $\mathcal{D}$ being fine, in general.

For reasons that will eventually become apparent, we elect to express this partition in terms of subsets of $\mathcal{H}$ itself, as opposed to subsets of cosets of $\mathcal{H}$. In particular, in the notation of (8), we have $\mathcal{D}_0 = \mathcal{D}_5 = \mathcal{D}_{15} = \emptyset, \mathcal{D}_1 = \mathcal{D}_2 = \mathcal{D}_3 = \emptyset, \mathcal{D}_4 = \{5, 10\}, \mathcal{D}_6 = \mathcal{D}_7 = \mathcal{D}_{13} = \mathcal{D}_9 = \{0, 5\}$, and $\mathcal{D}_{11} = \mathcal{D}_{12} = \mathcal{D}_3 = \mathcal{D}_{14} = \{0, 10\}$. Under this notation, the portion of $\mathcal{D}$ that lies in the $g$th coset of $\mathcal{H}$ is $\mathcal{D} \cap (\mathcal{H} + g) = g + [\mathcal{H} \cap (\mathcal{D} - g)] = g + \mathcal{D}_g$.

As evidenced by this example, the set $g + \mathcal{D}_g$ only depends on the coset of $\mathcal{H}$ to which $g$ belongs: when $g = g + \mathcal{H}$ and $g^\prime = g' + \mathcal{H}$ are equal, we have $g + \mathcal{D}_g = \mathcal{D} \cap (g + \mathcal{H}) = \mathcal{D} \cap (g' + \mathcal{H}) = g' + \mathcal{D}_{g'}$. On the other hand, $\mathcal{D}_g$ itself depends on one’s choice of coset representative: when $g = g'$, we have $\mathcal{D}_g = (g' - g) + \mathcal{D}_{g'}$, which is not equal to $\mathcal{D}_{g'}$ in general.

**Theorem 3.3.** If $\mathcal{D}$ is a difference set for an abelian group $\mathcal{G}$ of order $G$ and $\mathcal{H}$ is any subgroup of $\mathcal{G}$ of order $H$ that is disjoint from $\mathcal{D}$, then $H \leq \frac{G}{S+1}$ where $S = \lfloor \frac{D(G-1)}{G} \rfloor$. Moreover, the following are equivalent:

(i) $H = \frac{G}{S+1}$, that is, $\mathcal{D}$ is $\mathcal{H}$-fine;

(ii) $(\mathcal{F}^* \chi_\mathcal{D})(\gamma) = -\frac{D}{S}$ for all $\gamma \in \mathcal{H}^\perp, \gamma \neq 1$;

(iii) $\#(\mathcal{D}_g) = \frac{D}{S}$ for all $g \notin \mathcal{H}$, where $\mathcal{D}_g := \mathcal{H} \cap (\mathcal{D} - g)$, i.e., $\chi_\mathcal{D} \ast \chi_\mathcal{H} = \frac{D}{S} \chi_{\mathcal{H}^c}$.

As a consequence, if $\mathcal{D}$ is fine then $S$ is necessarily an integer that divides $D$, implying the order $D - \Lambda = \frac{D^2}{S^2}$ of $\mathcal{D}$ is necessarily a perfect square.

**Proof.** Recall that since $\mathcal{D}$ is a difference set for $\mathcal{G}$, the DFT of its characteristic function satisfies $(\mathcal{F}^* \chi_\mathcal{D})(1) = D$ and $| (\mathcal{F}^* \chi_\mathcal{D})(\gamma) | = \frac{D}{S}$ for all $\gamma \neq 1$. The fact that $\mathcal{H}$ is disjoint from $\mathcal{D}$ along with the Poisson summation formula implies

$$0 = \langle \chi_\mathcal{H}, \chi_\mathcal{D} \rangle = \frac{1}{G} \langle \mathcal{F}^* \chi_\mathcal{H}, \mathcal{F}^* \chi_\mathcal{D} \rangle = \frac{H}{G} \langle \chi_{\mathcal{H}^\perp}, \mathcal{F}^* \chi_\mathcal{D} \rangle = \frac{H}{G} \left( D + \sum_{\gamma \in \mathcal{H}^\perp \setminus \{1\}} (\mathcal{F}^* \chi_\mathcal{D})(\gamma) \right),$$

where $\mathcal{H}^\perp$ is the $\frac{G}{H}$-element annihilator of $\mathcal{H}$. Multiplying by $\frac{GS}{HD}$ and rearranging then gives

$$S = \sum_{\gamma \in \mathcal{H}^\perp \setminus \{1\}} [-\frac{S}{D}(\mathcal{F}^* \chi_\mathcal{D})(\gamma)],$$

namely an expression for $S$ as a sum of $\frac{G}{H} - 1$ unimodular numbers. In particular, applying the triangle inequality to (9) immediately gives $S \leq \frac{G}{H} - 1$, namely the claim that $H \leq \frac{G}{S+1}$.

(i $\iff$ ii) If $H = \frac{G}{S+1}$, (9) expresses $S$ as a sum of $S$ unimodular numbers, implying each of these numbers is 1, that is, $-\frac{S}{D}(\mathcal{F}^* \chi_\mathcal{D})(\gamma) = 1$ for all $\gamma \in \mathcal{H}^\perp, \gamma \neq 1$, namely (ii). Conversely, if (ii) holds, then $-\frac{S}{D}(\mathcal{F}^* \chi_\mathcal{D})(\gamma) = 1$ for all $\gamma \in \mathcal{H}^\perp, \gamma \neq 1$ and so (9) gives $S \leq \frac{G}{H} - 1$, namely (i).
(ii ⇒ iii) Since \((F^*\chi_D)(1) = D\), (ii) can be restated as saying \((F^*\chi_D)\chi_{H^\perp} = \frac{D}{S}(G\delta_1 - H\chi_{H^\perp})\). Applying the Poisson summation formula thus gives

\[
F^*(\chi_D\chi_H) = H(F^*\chi_D)\chi_{H^\perp} = \frac{D}{S}(G\delta_1 - H\chi_{H^\perp}) = \frac{D}{S}F^*(1 - \chi_H) = \frac{D}{S}F^*\chi_{H^c},
\]

namely that \(\chi_D \ast \chi_H = \frac{D}{S}\chi_{H^c}\). Since

\[\sum_{\gamma' \in G} \chi_D(\gamma')\chi_H(\gamma - \gamma') = \#(D \cap (g + H)) = \#(H \cap (D - g)) = \#(D_g)\]

for any \(g \in G\), this equates to having \(\#(D_g) = \frac{D}{S}\) for all \(g \notin H\).

(iii ⇒ i) The cosets of \(H\) partition \(G\), and so \(D\) can be partitioned as \(D = \cup_{g \in G}(g + D_g)\). Since \(D\) is disjoint from \(H\), \(D_g = \emptyset\) for the unique coset representative \(g\) that lies in \(H\). Combining these facts with (iii) gives \(D = \#(D) = \sum_{g \in G \setminus H} \#(D_g) = 0 + (\frac{G}{S} - 1)\frac{D}{S}\), namely (i).

For the final conclusions, we now assume \(D\) is finite, meaning there exists some subgroup \(H\) of \(G\) that is disjoint from \(D\) and satisfies (i)–(iii). Here, (i) implies \(S = \frac{G}{H} - 1\) is necessarily an integer, and (iii) then gives that \(S\) divides \(D\). Thus, the order \(D - \Lambda = \frac{D}{S}\) of \(D\) is a perfect square. □

For an alternative, more combinatorial proof of some of these same ideas, recall that when \(D\) is a difference set for \(G\), every nonzero member of \(G\) appears exactly \(\Lambda = \frac{D(D-1)}{G} = D - \frac{D^2}{S}\) times in its difference table. As such, exactly \((H - 1)\Lambda\) of these differences are nontrivial members of \(H\). Moreover, any given \(g, g' \in G\) have the property that \(g - g' \in H\) if and only if \(g, g'\) lie in a common coset of \(H\). In particular, partitioning \(D\) as \(D = \cup_{g \in G \setminus H}(g + D_g)\) leads to a corresponding partition of the nonzero \(H\)-valued entries of the difference table of \(D\):

\[
\{(d, d') \in D \times D : 0 \neq d - d' \in H\} = \bigcup_{g \in G \setminus H} \{(d, d') \in (g + D_g) \times (g + D_g) : d \neq d'\}.
\]

Counting these sets gives \((H - 1)\Lambda = \sum_{g \in G \setminus H} D_g(D_g - 1) = -D + \cup_{g \in G \setminus H} D_g^2\) where \(D_g := \#(D_g)\). As above, the fact that \(D\) is disjoint from \(H\) implies that \(D_g = 0\) for the unique coset representative \(g\) that lies in \(H\), that is, such that \(g = 0\). Overall, we have \(\frac{G}{H} - 1\) nonnegative integers \(\{D_g\}_{g \in G \setminus H \neq 0}\) such that \(\sum_{g \neq 0} D_g = D\) and \(\sum_{g \neq 0} D_g^2 = D + (H - 1)\Lambda = (D - \Lambda)H\). Applying the Cauchy-Schwarz inequality to this sequence thus gives

\[
D^2 \leq (\frac{G}{H} - 1)(D - \Lambda)^2 + HA^2,
\]

where equality holds if and only if \(D_g\) is constant over all \(g \notin H\). Now recall that \(\Lambda = D - \frac{D^2}{S}\) where \(S^2 = \frac{D(G-1)}{(G-D)}\) and so \(\frac{GS^2\Lambda}{DB^2} = G(S^2 - 1) = S^2 - 1\). Multiplying (10) by \(\frac{GS^2}{DB^2}\) thus gives

\[
\frac{G}{H}S^2 \leq \frac{GS^2}{DB^2}(\frac{G}{H} - 1)(\frac{G}{H} - 1)^2 + HA\Lambda = (\frac{G}{H} - 1)(\frac{G}{H} + \frac{GS^2\Lambda}{DB^2}) = (\frac{G}{H} - 1)(\frac{G}{H} + S^2 - 1),
\]

that is, \(S^2 \leq (\frac{G}{H} - 1)^2\), namely the claim in Theorem (3.3) that \(H \leq \frac{G}{S+1}\). Moreover, when (i) holds, then reversing the above argument gives equality in (10), meaning \(\{D_g\}_{g \in G \setminus H \neq 0}\) consists of \(S\) equal numbers that sum to \(D\), implying (iii).

For yet another alternative proof of one of these facts, note that if \(D\) is disjoint from a subgroup \(H\) of \(G\) of order \(H > \frac{G}{S+1}\), then (1) implies that \(\{\varphi_\gamma\}_{\gamma \in \hat{G}}\) is a linearly dependent subsequence of the harmonic ETF \(\{\varphi_\gamma\}_{\gamma \in \hat{G}}\) that consists of fewer than \(S + 1\) vectors: since \(\frac{1}{S} = \text{coh}(\{\varphi_\gamma\}_{\gamma \in \hat{G}})\), this violates a fact from compressed sensing known as the spark bound (18).
3.2. A new representation of harmonic ETFs arising from fine difference sets

As summarized in Theorem 7.5 of [18], several types of difference sets are known to be fine, including McFarland difference sets, the complements of twin prime power difference sets, and the appropriately shifted complements of “half” of all Singer difference sets. Moreover, by Theorem 6.2 of [18], every ETF that is comprised of regular simplices—including every harmonic ETF arising from a fine difference set—gives rise to an ECTFF. Below, we show that some of these ECTFFs are EITFFs while others are not. To do this, it helps to introduce some more notation.

As before, letting \( \{ \varphi_{\gamma} \}_{\gamma \in G} \) be the harmonic ETF arising from a difference set \( D \) that is fine with respect to \( H \), we have that for any \( \gamma \in \hat{G} \), the subsequence \( \{ \varphi_{\gamma'} \}_{\gamma' \in H^\perp} \) indexed by the \( \gamma \)th coset of \( H^\perp \) is a regular simplex for its span. Here, to facilitate our work below, we elect to instead index the vectors in every such regular simplex by a common set, namely \( H^\perp \). To be precise, for any \( \gamma \in \hat{G} \), let \( \Phi_\gamma \) be the synthesis operator of \( \{ \varphi_{\gamma'} \}_{\gamma' \in H^\perp} \), that is,

\[
\Phi_\gamma \in \mathbb{C}^{D \times H^\perp}, \quad \Phi_\gamma(d, \gamma') := \varphi_{\gamma'}(d) = \frac{1}{\sqrt{D}} \gamma(d) \gamma'(d).
\]

(11)

This benefit comes at a small price: though both \( \{ \varphi_{\gamma} \}_{\gamma \in G} \) and \( \{ \varphi_{\gamma'} \}_{\gamma' \in H^\perp} \) depend on \( \gamma \), the former only depends on the coset \( \gamma = H^\perp \) to which \( \gamma \) belongs, whereas \( \Phi_\gamma \) is representative dependent. That said, when \( \gamma = \gamma' \), we have \( \Phi_\gamma = \Phi_{\gamma'} \) \( T^{\gamma} \) where, for any \( \gamma \in H^\perp \), \( T^{\gamma} \) is the “translation by \( \gamma \) operator over \( H^\perp \), namely the \( (H^\perp \times H^\perp) \)-indexed permutation matrix defined by \( T^{\gamma}(\gamma_1, \gamma_2) = 1 \) if and only if \( \gamma_1 \gamma_2^{-1} = \gamma \). As such, the column space of \( \Phi_\gamma \) is independent of coset representative. In particular, the following notation for these subspaces is well defined:

\[
\{ U_\gamma \}_{\gamma \in G/H^\perp}, \quad U_\gamma := \text{span}\{ \varphi_{\gamma'} \}_{\gamma' \in H^\perp} = C(\Phi_\gamma).
\]

(12)

As mentioned above, the results of [18] imply that if \( D \) is \( H \)-fine then \( \{ U_\gamma \}_{\gamma \in G} \) is an ECTFF for \( \mathbb{C}^D \). Below, we show that this ECTFF is an EITFF for \( \mathbb{C}^D \) if and only if \( D_g = H \cap (D - g) \) is a difference set for \( H \) for every \( g \in G \). This is nontrivial since the techniques of [18] do not easily generalize to this harder problem. There, the key idea is that since \( \{ \varphi_{\gamma'} \}_{\gamma' \in H^\perp} \) is an ETF(\( S, S+1 \)) for \( U_\gamma \) where \( S = \frac{(G-1)}{2}D \), the orthogonal projection operator onto \( U_\gamma \) can be written as \( P_\gamma = \frac{S}{S-1} \Phi_\gamma \Phi_\gamma^* \). Here, since \( \{ \varphi_{\gamma} \}_{\gamma \in G} \) is an ETF for \( \mathbb{C}^D \), we also have \( \| \{ \varphi_{\gamma_1}, \varphi_{\gamma_2} \} \|_2^2 = \frac{1}{S} \) for any \( \gamma_1, \gamma_2 \in H^\perp \) provided \( \gamma \neq \gamma' \). Together, these facts imply that for any \( \gamma \neq \gamma' \),

\[
\text{Tr}(P_\gamma P_\gamma^*) = \frac{S^2}{(S+1)^2} \| \Phi_\gamma \Phi_\gamma^* \|_F^2 = \frac{S^2}{(S+1)^2} \sum_{\gamma_1 \in H^\perp} \sum_{\gamma_2 \in H^\perp} \| \varphi_{\gamma_1}, \varphi_{\gamma_2} \|^2 = 1.
\]

(13)

This means these \( N = H \) subspaces of \( \mathbb{C}^D \) of dimension \( M = S \) achieve equality in (2) and so form an ECTFF for \( \mathbb{C}^D \). solving for \( G \) in \( S^2 = \frac{(G-1)D}{G-D} \) gives

\[
G = \frac{(S^2-1)D}{S^2-D}, \quad \text{i.e.,} \quad H = \frac{G}{S+1} = \frac{(S-1)D}{S^2-D}, \quad \text{i.e.,} \quad \frac{S(SH-D)}{D(H-1)} = 1.
\]

(14)

One could conceivably continue this approach to characterize when \( \{ U_\gamma \}_{\gamma \in G} \) is an EITFF for \( \mathbb{C}^D \) having \( P_\gamma = \frac{S}{S-1} \Phi_\gamma \Phi_\gamma^* \), the goal is to characterize when there exists \( \sigma^2 \) such that \( P_\gamma P_\gamma^* = \sigma^2 P_\gamma \) for all \( \gamma \neq \gamma' \). We did not pursue this approach, and it seems more complicated than our alternative.

We instead construct orthonormal bases for \( \{ U_\gamma \}_{\gamma \in G} \) that permit the singular values of their cross-Gram matrices to be computed explicitly. To be precise, for any \( \gamma \in \hat{G} \), we obtain an isometry \( E_\gamma \) so that \( \Phi_\gamma = E_\gamma \Psi \) where \( \Psi \) is the synthesis operator of a harmonic regular \( S \)-simplex that naturally arises in this context:

\[
\Psi \in \mathbb{C}^{(G/H) \times H^\perp}, \quad \Psi(\gamma, \gamma) = \frac{1}{\sqrt{S}} \gamma(g).
\]

(15)
Lemma 3.4. \( \Phi \) that satisfies

Moreover, in this case, \( S \)-fine; see Definition 3.1. Then a \( \frac{D}{S} \)-element subset \( B \) of \( \mathcal{H} \) is a difference set for \( \mathcal{H} \) if and only if

\[
\langle \psi, \psi \rangle = \frac{1}{S} \sum_{g \in G/H \setminus \{0\}} (\gamma^{-1} \gamma')(g) = \frac{1}{S} \sum_{g \in G/H} (\gamma^{-1} \gamma')(g) = -\frac{1}{S}.
\]

Here, we have used the fact that \( \sum_{g \in G/H} \gamma(g) = 0 \) for all \( \gamma \in H^1 \), \( \gamma \neq 1 \), something which follows from multiplying this equation by \( \gamma(g_0) - 1 \neq 0 \). Thus, \( \Psi^* \Psi = \frac{1}{S} [(S + 1) I - J] \). This in turn implies \( \Psi^* \Psi = \frac{S + 1}{S} I \), a fact which is also straightforward to prove directly.

It is not surprising that \( \Phi_\gamma = E_\gamma \Psi \) for some isometry \( E_\gamma \): though we do not rely on this fact in our proof below, the interested reader can use (17) to verify that \( \Phi_\gamma \) and \( \Psi \) have the same Gram matrix, which in turn implies that such an isometry necessarily exists. What is remarkable however is that this \( E_\gamma \) is necessarily simple and sparse: if \( \Phi_\gamma = E_\gamma \Psi \) then multiplying this equation by \( \Psi^* \) gives \( E_\gamma = \frac{S}{S + 1} \Phi_\gamma \Psi^* \) and so for any \( d \in D \), \( \gamma \in G/H \setminus \{0\} \),

\[
E_\gamma(d, \gamma) = \frac{S}{S + 1} \sum_{\gamma' \in H^1} \Phi_\gamma(d, \gamma') \langle \gamma(d), \gamma' \rangle = \frac{\sqrt{S}}{(S + 1)^{1/2} D} \gamma(d) \sum_{\gamma' \in H^1} \gamma'(d - g),
\]

at which point the Poisson summation formula and the fineness of \( D \) implies

\[
E_\gamma(d, \gamma) = \frac{\sqrt{S}}{(S + 1)^{1/2} D} \gamma(d) \langle F \chi_{H^1} \rangle (d - g) = \frac{\sqrt{S}}{(S + 1)^{1/2} D} \gamma(d) \frac{H}{\sqrt{D}} \chi_{H^1}(d - g) = \frac{\sqrt{S}}{D} \gamma(d), \quad \frac{d}{D} \neq \frac{\gamma}{S}.
\]

Moreover, if \( E_\gamma \) is an isometry, then its columns are unit norm, giving yet a third way of proving that (i) \( \Rightarrow \) (iii) in Theorem 3.3. Below, for the sake of an elementary self-contained proof, we instead take the above expression for \( E_\gamma \) as a given, and use Theorem 3.3 to show that it is an isometry that satisfies \( \Phi_\gamma = E_\gamma \Psi \). Both here and later on, we shall also make use of the following fact:

**Lemma 3.4.** Let \( D \) be a difference set for \( G \) that is \( H \)-fine; see Definition 3.1. Then a \( \frac{D}{S} \)-element subset \( B \) of \( \mathcal{H} \) is a difference set for \( \mathcal{H} \) if and only if

\[
|\langle F^* \chi_B \rangle(\gamma)\rangle|^2 = \frac{D}{S^2} |1 + (S - 1) \chi_{H^1} (\gamma)|, \quad \forall \gamma \in \hat{G}.
\]

Moreover, in this case, \( S^3 \) necessarily divides \( D^2 \).

**Proof.** By (13), \( H - 1 = \frac{(S - D)D}{S^2} - 1 = \frac{S(D - S)}{S^2} \), which in turn implies \( \frac{1}{S} \gamma(D - 1) = \frac{D}{S} - \frac{D^2}{S^2} \). As such, \( B \) is a difference set for \( \mathcal{H} \) if and only if for every \( g \in \mathcal{H} \), \# \{ \( (b, b') \in B : g = b - b' \} = \frac{D}{S} - \frac{D^2}{S^2} ; \)

since Theorem 3.3 gives that \( S \) divides \( D \), this is only an integer when \( S^3 \) divides \( D^2 \). Moreover, since \( B \) is a \( \frac{D}{S} \)-element subset of \( \mathcal{H} \), this equates to having \( \chi_B \in \mathbb{C}^G \) satisfy

\[
\langle \chi_B \ast \tilde{\chi}_B \rangle(g) = \# \{ (b, b') \in B : g = b - b' \} = \begin{cases} \frac{D}{S}, & g = 0, \\ \frac{D}{S} - \frac{D^2}{S^2}, & g \in \mathcal{H} \setminus \{0\}, \\ 0, & g \notin \mathcal{H}. \end{cases}
\]

namely to having \( \chi_B \ast \tilde{\chi}_B = \frac{D}{S} |D \delta_0 + (S^2 - D) \chi_{\mathcal{H}^1}|. \) Taking Fourier transforms, and again using (11) and the Poisson summation formula, this equates to our claim:

\[
|\langle F^* \chi_B \rangle(\gamma)\rangle|^2 = \frac{D}{S^2} |D \delta_0 + (S^2 - D) \chi_{\mathcal{H}^1} (\gamma)| = \frac{D^2}{S^2} |1 + (S - 1) \chi_{\mathcal{H}^1} (\gamma)|, \quad \forall \gamma \in \hat{G}. \]
Theorem 3.5. Let \( \mathcal{D} \) be a difference set for \( \mathcal{G} \) that is \( \mathcal{H} \)-fine; see Definition 3.4. Define \( \mathcal{D}_g, \Phi_\gamma \) and \( \Psi \) by (8), (11) and (13), respectively. For any \( \gamma \in \hat{\mathcal{G}} \), let
\[
  E_\gamma \in \mathbb{C}^{D \times (\mathcal{G}/\mathcal{H}) \setminus \{0\}}, \quad E_\gamma(d, \bar{g}) = \frac{1}{\sqrt{|D|}} \begin{cases} \sqrt{|D|} \gamma(d), & \bar{g} = \bar{g}', \\ 0, & \bar{d} \neq \bar{g}'. \end{cases}
\] (16)

Then:

(a) For any \( \gamma \in \hat{\mathcal{G}} \), \( \Phi_\gamma = E_\gamma \Psi \) where \( E_\gamma \) is an isometry, i.e. \( E_\gamma^* E_\gamma = I \).

(b) For any \( \gamma, \gamma' \in \hat{\mathcal{G}} \), \( E_\gamma^* E_\gamma' \) is a diagonal matrix with
\[
  (E_\gamma^* E_\gamma')(\bar{g}, \bar{g}') = \frac{S}{|D|} \sum_{d \in D, \bar{d} = \bar{g}} (\gamma^{-1} \gamma')(d), \quad \forall \bar{g} \in \mathcal{G}/\mathcal{H} \setminus \{0\}.
\]

(c) The sequence of subspaces \( \{U_{\gamma} \}_{\gamma \in \mathcal{G}/\mathcal{H}^+} \) given in (12) is an EITFF for \( \mathcal{D}' \) if and only if every \( \mathcal{D}_g \) is a difference set for \( \mathcal{H} \). In this case, \( S^3 \) necessarily divides \( D^2 \).

(d) If every \( \mathcal{D}_g \) is a difference set for \( \mathcal{H} \), then for every \( \gamma \in \mathcal{H}^+ \), the \( (\mathcal{G}/\mathcal{H}) \)-circulant matrix
\[
  C_\gamma \in \mathbb{C}^{(\mathcal{G}/\mathcal{H}) \times (\mathcal{G}/\mathcal{H})}, \quad C_\gamma(\bar{g}, \bar{g}') = \frac{S^3}{|D|} \sum_{d \in D} \gamma(d),
\]

is a conference matrix, that is, satisfies \( C_\gamma C_\gamma = S I \) where \( |C_\gamma(\bar{g}, \bar{g}')| = \begin{cases} 0, & \bar{g} = \bar{g}', \\ 1, & \bar{g} \neq \bar{g}'. \end{cases} \)

Proof. To prove the first part of (a), note that since \( \mathcal{D} \) is disjoint from \( \mathcal{H} \), any \( d \in \mathcal{D} \) lies in exactly one nonidentity coset of \( \mathcal{H} \), implying that for any \( \gamma' \in \mathcal{H}^+ \),
\[
  (E_\gamma \Psi)(d, \gamma') = \sum_{\bar{g} \in \mathcal{G}/\mathcal{H} \setminus \{0\}} E_\gamma(d, \bar{g}) \Psi(\bar{g}, \gamma') = \frac{|D|}{\sqrt{|D|}} \gamma(d) \Psi(\bar{d}, \gamma') = \frac{1}{\sqrt{|D|}} \gamma(d) \gamma'(d) = \Phi_\gamma(d, \gamma').
\]

Next, to prove the second part of (a) as well as (b), note for any \( \gamma, \gamma' \in \hat{\mathcal{G}} \) and \( \bar{g}, \bar{g}' \in \mathcal{G}/\mathcal{H} \setminus \{0\} \),
\[
  (E_\gamma^* E_\gamma')(\bar{g}, \bar{g}') = \sum_{d \in D} [E_\gamma(d, \bar{g})]^* E_\gamma'(d, \bar{g}') = \frac{S}{|D|} \sum_{\bar{d} = \bar{g}} (\gamma^{-1} \gamma')(d).
\]

When \( \bar{g} \neq \bar{g}' \), the above sum is empty, implying \( (E_\gamma^* E_\gamma')(\bar{g}, \bar{g}') = 0 \). That is, \( E_\gamma^* E_\gamma' \) is diagonal. Moreover, since \( \{d \in \mathcal{D} : \bar{d} = \bar{g}\} = \{d \in \mathcal{D} : d \in \mathcal{g} + \mathcal{H}\} = \mathcal{D} \cap (\mathcal{g} + \mathcal{H}) = \mathcal{g} + \mathcal{D}_g \), continuing the above equation gives the \( \gamma \)th diagonal entry of this matrix is
\[
  (E_\gamma^* E_\gamma')(\bar{g}, \bar{g}) = \frac{S}{|D|} \sum_{d \in D, \bar{d} = \bar{g}} (\gamma^{-1} \gamma')(d) = \frac{S}{|D|} \sum_{h \in \mathcal{D}_g} (\gamma^{-1} \gamma')(\mathcal{g} + h) = \frac{S}{|D|} \gamma'(-\gamma')(\mathcal{g}^* \chi_{\mathcal{D}_g})(\gamma'(-\gamma'))^{-1}.
\]

In particular, (b) holds. Moreover, in the case where \( \gamma = \gamma' \), this along with Theorem 3.5(c) imply \( (E_\gamma^* E_\gamma)(\bar{g}, \bar{g}) = \frac{S}{|D|} (\mathcal{g}^* \chi_{\mathcal{D}_g})(1) = \frac{S}{|D|} \#(\mathcal{D}_g) = 1 \) for all \( \bar{g} \in \mathcal{G}/\mathcal{H} \setminus \{0\} \). Thus, \( E_\gamma^* E_\gamma = I \), as claimed in the second part of (a).
For (c), recall that $\mathcal{U}_γ$ is the column space $Φ_γ$. By (a), $\mathcal{U}_γ = C(Φ_γ) = C(E_γΨ) ⊆ C(E_γ)$. Moreover, multiplying $Φ_γ = E_γΨ$ by $Ψ^*$ gives $E_γ = \frac{1}{S} Φ_γΨ^*$ and so $C(E_γ) ⊆ C(Φ_γ) = \mathcal{U}_γ$. Thus, $C(E_γ) = \mathcal{U}_γ$. When combined with the fact that $E_γ^*E_γ = I$, this implies that the columns of $E_γ$ form an orthonormal basis for $\mathcal{U}_γ$. As discussed in Section 2, we thus have that $\{\mathcal{U}_γ\}_{γ ∈ G/H}^*$, a sequence of $N = H$ subspaces of $C^D$ of dimension $M = S$, is an EITFF for $C^D$ if and only if for all $γ ≠ γ'$, every singular value of $E_γ^*E_γ$, is equal to $\left|\frac{MN-D}{D}\right|^2 = \left|\frac{SH-D}{D}\right|^2 = \frac{1}{V_γ}$, cf. [3] and [14]. Moreover, since $E_γ^*E_γ$, is diagonal, its singular values are the absolute values of its diagonal entries. Altogether, we have that $\{U_γ\}_{γ ∈ G/H}^*$ is an EITFF for $C^D$ if and only if

$$||E_γ^*E_γ||_{Fro} = \sum_{γ ∈ G/H \setminus \{0\}} ||(E_γ^*E_γ)(γ, γ')||^2 = \sum_{γ ∈ G/H \setminus \{0\}} ||x_γ-1(γ)||^2 = 1.$$
in light of (14), these \( N = H \) subspaces of \( \mathbb{C}^D \) of dimension \( M = S \) thus achieve equality in (2).

In particular, if \( D \) is fine and every \( D_g \) is a difference set for \( \mathcal{H} \), then \( x(0) = 0 \) while, by (17), we have \(|x(\bar{c})| = |(E_{\gamma}E_{\gamma})(\bar{g}, \bar{g'})| = \frac{1}{\sqrt{8}} \) for all \( \bar{g} \neq \bar{0} \). Since \( C_{\gamma} \) is a \((G/\mathcal{H})\)-circulant matrix with \( C_{\gamma}(\bar{g}, \bar{g'}) = \sqrt{S}x_{\gamma}(\bar{g} - \bar{g'}) \), this implies the diagonal entries of \( C_{\gamma} \) are zero while its off-diagonal entries are unimodular. Moreover, \( C_{\gamma}^\dagger C_{\gamma} = S1 \) since

\[
(C_{\gamma}^\dagger C_{\gamma})(\bar{g}, \bar{g'}) = S \sum_{\bar{g}' \in G/\mathcal{H}} |x_{\gamma}(\bar{g}' - \bar{g})|^2 x_{\gamma}(\bar{g}' - \bar{g'}) = S(\bar{x}_{\gamma} \ast x_{\gamma})(\bar{g} - \bar{g'}) = S\delta(\bar{g} - \bar{g'}).)
\]

We give the difference sets that satisfy the condition of (c) a name:

**Definition 3.6.** We say a difference set \( D \) for a finite abelian group \( \mathcal{G} \) is an amalgam if it is \( \mathcal{H} \)-fine for some subgroup \( \mathcal{H} \) of \( \mathcal{G} \)—see Definition 3.1—and moreover for every \( g \in \mathcal{G}, D_g := \mathcal{H} \cap (D - g) \) is a difference set for \( \mathcal{H} \).

One immediate consequence of this result is that no EITFF that arises from an amalgam via Theorem 3.5(c) disproves Conjecture 2.1: if the \( \mathcal{H} \) subspaces (12) of \( \mathcal{C}^D \), each of dimension \( S \), form an EITFF for \( \mathcal{C}^D \), then each \( D_g \) with \( g \not\in \mathcal{H} \) is a \( \frac{D}{S} \)-element difference set for \( \mathcal{H} \) and so yields a harmonic ETF((\( \frac{D}{S} \), \( \mathcal{H} \)). This in fact suggests that the EITFFs produced by Theorem 3.5 might arise from tensor products of such ETFs with an orthonormal basis. We return to this idea in the next section.

We also emphasize that the above proofs of Theorems 3.3 and 3.5 are self-contained: though these results were strongly motivated by those of [18], our proofs here do not rely on facts from [18] in any formal way. In particular, though [18] implies that \( \Phi_{\gamma} \) is the synthesis operator of a regular simplex for its span, we do not assume this fact in our proofs above. In fact, we instead provide an alternative proof of this fact, directly proving \( \Phi_{\gamma} = E_{\gamma} \Psi \) where \( E_{\gamma} \) is an isometry and \( \Psi \) is the synthesis operator of a regular simplex.

**Example 3.7.** As a continuation of Example 3.2 recall that \( D = \{6, 11, 7, 12, 13, 3, 9, 14\} \) is a difference set for \( \mathcal{G} = \mathbb{Z}_{15} \). To form the corresponding harmonic ETF, we extract the corresponding 8 rows from the 15 \times 15 character table of \( \mathcal{G} \). Here, we regard \( \mathcal{G} \) as \( \mathbb{Z}_{15} \), identifying \( n \in \mathbb{Z}_{15} \) with the character \( g \mapsto \omega^{ng} \) where \( \omega = e^{2\pi i/15} \). (As such, throughout this example, we use additive notation on \( \mathcal{G} \).) That is, the columns \( \{\varphi_n\}_{n \in \mathbb{Z}_{15}} \) of

\[
\Phi = \frac{1}{\sqrt{8}} \begin{bmatrix}
\omega^0 & \omega^6 & \omega^{12} & \omega^3 & \omega^9 & \omega^0 & \omega^6 & \omega^{12} & \omega^3 & \omega^9 \\
\omega^0 & \omega^{11} & \omega^7 & \omega^{14} & \omega^{10} & \omega^6 & \omega^2 & \omega^{13} & \omega^9 & \omega^4 & \omega^1 & \omega^{12} & \omega^8 & \omega^4 \\
\omega^0 & \omega^7 & \omega^{14} & \omega^6 & \omega^{13} & \omega^5 & \omega^{12} & \omega^4 & \omega^{11} & \omega^{10} & \omega^2 & \omega^9 & \omega^1 & \omega^8 \\
\omega^0 & \omega^{12} & \omega^9 & \omega^6 & \omega^3 & \omega^0 & \omega^{12} & \omega^9 & \omega^6 & \omega^3 & \omega^0 & \omega^{12} & \omega^9 & \omega^6 \\
\omega^0 & \omega^{13} & \omega^{11} & \omega^9 & \omega^7 & \omega^5 & \omega^3 & \omega^1 & \omega^{14} & \omega^{12} & \omega^{10} & \omega^8 & \omega^6 & \omega^4 & \omega^2 \\
\omega^0 & \omega^6 & \omega^{12} & \omega^3 & \omega^0 & \omega^{12} & \omega^3 & \omega^0 & \omega^{12} & \omega^3 & \omega^0 & \omega^{12} & \omega^3 & \omega^0 \\
\omega^0 & \omega^9 & \omega^3 & \omega^{12} & \omega^6 & \omega^0 & \omega^9 & \omega^3 & \omega^{12} & \omega^6 & \omega^0 & \omega^9 & \omega^3 & \omega^{12} \\
\omega^0 & \omega^{14} & \omega^{13} & \omega^{12} & \omega^{11} & \omega^9 & \omega^{10} & \omega^8 & \omega^{11} & \omega^6 & \omega^5 & \omega^4 & \omega^3 & \omega^2 & \omega^1
\end{bmatrix}
\]

form an ETF(8, 15), having \(|\langle \varphi_n, \varphi_{n'} \rangle| = |\frac{\mathcal{G}D}{D(G - 1)}|^{\frac{1}{2}} = \frac{1}{4} \) for all \( n \neq n' \), and thus achieving equality in the Welch bound (1). Letting \( S = 4 \) be the reciprocal of this bound, we further have that \( D \) is fine, being disjoint from the unique subgroup of \( \mathcal{G} \) of order \( H = \frac{D}{S} = 3 \), namely \( \mathcal{H} = \{0, 5, 10\} \). As such, any \( 8 \times 5 \) submatrix of \( \Phi \) whose columns are indexed by a coset of \( \mathcal{H}^\perp \) have the property
that these columns sum to zero à la (7) and moreover form a regular simplex for their 4-dimensional span. Here, under our identification of $\mathcal{G}$ with $\mathbb{Z}_{15}$, $\mathcal{H}^+$ corresponds to those $n \in \mathbb{Z}_{15}$ that have the property that $\omega^{n+1} = 1$ for all $h \in \mathcal{H} = \{0, 5, 10\}$, namely $\{0, 3, 6, 9, 12\}$.

Here, for any $n \in \mathbb{Z}_{15}$, the matrix $\Phi_n$, defined by (11), is the $8 \times 5$ submatrix of $\Phi$ whose columns are indexed by the $n$th coset of $\mathcal{H}^+$, beginning with $n$, namely $\Phi_n = \{ \varphi_n, \varphi_{n+3}, \varphi_{n+6}, \varphi_{n+9}, \varphi_{n+12} \}$. Each $\Phi_n$ is unique, but $\Phi_n$ and $\Phi_{n'}$ are related via a $5 \times 5$ permutation matrix whenever $n - n' \in \mathcal{H}$. Moreover, any choice of coset representatives of $\mathcal{G}/\mathcal{H}$ yields a partition of the ETF’s vectors. For example, concatenating $\Phi_0$, $\Phi_1$ and $\Phi_2$ yields the matrix obtained by perfectly shuffling the columns of $\Phi$:

$$
\begin{bmatrix}
\Phi_0 & \Phi_1 & \Phi_2
\end{bmatrix} = \frac{1}{\sqrt{8}} \begin{bmatrix}
\omega^0 & \omega^3 & \omega^6 & \omega^9 & \omega^{12} \\
\omega^0 & \omega^3 & \omega^6 & \omega^9 & \omega^{12} \\
\omega^0 & \omega^3 & \omega^6 & \omega^9 & \omega^{12} \\
\omega^0 & \omega^3 & \omega^6 & \omega^9 & \omega^{12} \\
\omega^0 & \omega^3 & \omega^6 & \omega^9 & \omega^{12} \\
\omega^0 & \omega^3 & \omega^6 & \omega^9 & \omega^{12} \\
\omega^0 & \omega^3 & \omega^6 & \omega^9 & \omega^{12} \\
\omega^0 & \omega^3 & \omega^6 & \omega^9 & \omega^{12}
\end{bmatrix}.
$$

(18)

Meanwhile, removing the first row of the character table of $\mathbb{Z}_5 \cong \mathcal{G}/\mathcal{H}$ and then normalizing columns yields the synthesis operator (15) of a particularly nice regular 4-simplex:

$$
\Psi = \frac{1}{\sqrt{4}} \begin{bmatrix}
\omega^{12} & \omega^0 & \omega^0 & \omega^0 \\
\omega^9 & \omega^3 & \omega^6 & \omega^{12} \\
\omega^6 & \omega^9 & \omega^3 & \omega^{12} \\
\omega^3 & \omega^6 & \omega^9 & \omega^{12}
\end{bmatrix}.
$$

(19)

By Theorem 3.3(a), each $\Phi_n$ can be decomposed as $\Phi_n = E_n \Psi$, where $E_n$ is the $8 \times 4$ isometry defined in (16). In particular, the matrices $\Phi_0$, $\Phi_1$, $\Phi_2$ in (18) factor as products of

$$
E_0 = \frac{1}{\sqrt{2}} \begin{bmatrix}
1 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1
\end{bmatrix}, \\
E_1 = \frac{1}{\sqrt{2}} \begin{bmatrix}
\omega^6 & 0 & 0 & 0 \\
\omega^{11} & 0 & 0 & 0 \\
0 & \omega^7 & 0 & 0 \\
0 & \omega^{12} & 0 & 0 \\
0 & 0 & \omega^{13} & 0 \\
0 & 0 & \omega^3 & 0 \\
0 & 0 & 0 & \omega^9 \\
0 & 0 & 0 & \omega^{14}
\end{bmatrix}, \\
E_2 = \frac{1}{\sqrt{2}} \begin{bmatrix}
\omega^{12} & 0 & 0 & 0 \\
\omega^7 & 0 & 0 & 0 \\
0 & \omega^{14} & 0 & 0 \\
0 & \omega^9 & 0 & 0 \\
0 & 0 & \omega^{11} & 0 \\
0 & 0 & \omega^6 & 0 \\
0 & 0 & 0 & \omega^4 \\
0 & 0 & 0 & \omega^{13}
\end{bmatrix},
$$

(20)

with $\Psi$, respectively; here, the rows and columns of $E_n$ are indexed by $\mathcal{D} = \{6, 11, 7, 12, 13, 3, 9, 14\}$ and $\mathcal{G}/\mathcal{H}\{\emptyset\} = \{1, 2, 3, 4\}$, respectively. That is, each $\Phi_n$ is a regular simplex, being an isometric embedding of $\Psi$ into a particular 4-dimensional subspace of $\mathbb{C}^4$, namely into $\mathcal{U}_4 = C(E_n)$. Continuing, Theorem 3.3(b) implies every cross-gram matrix $E_n^* E_n$ is diagonal. Here, since $\omega^6 + \omega^{10} = -1$,

$$
E_0^* E_1 = E_1^* E_2 = -\frac{1}{2} \begin{bmatrix}
\omega & 0 & 0 & 0 \\
0 & \omega^2 & 0 & 0 \\
0 & 0 & \omega^8 & 0 \\
0 & 0 & 0 & \omega^4
\end{bmatrix}, \\
E_0^* E_2 = -\frac{1}{2} \begin{bmatrix}
\omega^2 & 0 & 0 & 0 \\
0 & \omega^4 & 0 & 0 \\
0 & 0 & \omega^6 & 0 \\
0 & 0 & 0 & \omega^8
\end{bmatrix}.
$$

(21)
This diagonality is crucial, since it means the singular values of $E_n^*E_n$—the cosines of the principal angles between $U_{17}$ and $U_{17}$—are the absolute values of its diagonal entries. In particular, (21) implies that every principal angle $\theta$ between any pair of the subspaces $U_{17}, U_{17}, U_{27}$ satisfies $\cos(\theta) = \frac{1}{2}$, meaning these three subspaces are equi-isoclinic. In fact, Theorem 3.5(c) gives that they form an EITFF for $\mathbb{C}^D$ since $D$ is an amalgam: from Example 3.2, recall that $D_g = \emptyset$ when $g \notin \mathcal{H}$ while for $g \notin \mathcal{H}, D_g$ is either $\{5, 10\}, \{0, 5\}$ or $\{0, 10\}$, each of which is a difference set for $\mathcal{H} = \{0, 5, 10\}$.

Since $D$ is an amalgam, Theorem 3.5(d) also applies: for any $n \notin \mathcal{H}^\perp$, we construct the first column of the $5 \times 5$ circulant conference matrix $C_n^*$ by reshaping the diagonal entries of $E_n^*E_n$ into a $4 \times 1$ vector, padding it with a leading 0 entry, and scaling the result by $\sqrt{5} = 2$. For example, in the $n = 1$ and $n = 2$ cases, the cross-Gram matrices in (21) yield the circulant conference matrices

$$C_1 = -\begin{bmatrix} 0 & \omega^4 & \omega^2 & \omega & \omega^8 \\ \omega & 0 & \omega^4 & \omega^2 & \omega^8 \\ \omega^2 & 0 & 0 & \omega^4 & \omega^8 \\ \omega^8 & \omega & 0 & 0 & \omega \\ \omega^4 & \omega^8 & \omega^2 & \omega & 0 \end{bmatrix}, \quad C_2 = -\begin{bmatrix} 0 & \omega^8 & \omega^4 & \omega^2 \\ \omega^2 & 0 & \omega^8 & \omega^4 \\ \omega^4 & \omega^2 & 0 & \omega^8 \\ \omega^8 & \omega^4 & 0 & \omega^8 \\ \omega^2 & \omega^8 & \omega^4 & 0 \end{bmatrix}.$$

Circulant conference matrices are interesting objects, and there does not seem to be much literature regarding them. Perhaps this is due to the long-known fact [39, 14, 42] that the only real-valued instances of such a matrix are $\pm[0, 1]$. The complex circulant conference matrices we obtain here are conceivably useful in certain applications where complex circulant Hadamard matrices are used, like waveform design for radar. While it is famously conjectured that real-valued $N \times N$ circulant Hadamard matrices only exist when $N \in \{1, 4\}$—the *circulant Hadamard conjecture*—infinite families of complex circulant Hadamard matrices are known; such objects are equivalent to the constant-amplitude, zero-autocorrelation (CAZAC) sequences of [3], and arise from quadratic chirps as well as Björck-Saffari sequences [4], for example.

Later on, we show that the above example is but the first member of an infinite family of known fine difference sets that are amalgams and so generate EITFFs and circulant conference matrices via Theorem 3.5. But first, we consider a subclass of amalgams that can be factored in terms of a certain type of relative difference set (RDS). As we shall see, such RDSs lend themselves to a related and yet distinct method for constructing circulant conference matrices.

4. Composite difference sets and amalgams

4.1. Composite difference sets

In the previous section, we showed that the ECTFF (12) arising from a fine difference set $D$ is an EITFF for $\mathbb{C}^D$ if and only if $D$ is an amalgam, that is, if and only if for every $g \in G$, the set $D_g = \mathcal{H}(D - g)$ is a difference set for $\mathcal{H}$. In this section, we show that there are an infinite number of fine difference sets that are amalgams, as well as an infinite number that are not. In fact, some but not all of these amalgams have an even stronger property, namely that any two nontrivial $D_g$ are translations of each other. For instance, from Example 3.2 recall that $D = \{6, 11, 7, 12, 13, 3, 9, 14\}$ is a difference set for $\mathbb{Z}_{15}$ that is $\mathcal{H}$-fine where $\mathcal{H} = \{0, 5, 10\}$ and, for $g \notin \mathcal{H}, D_g$ is either $\{5, 10\}$, $\{0, 5\}$ or $\{0, 10\}$. In particular, there is a choice of representatives of the nonidentity cosets of $\mathcal{G}/\mathcal{H}$ such that the corresponding $D_g$ are equal: $D_1 = D_2 = D_8 = D_4 = \{5, 10\}$. Applying this rationale in general, we see that if all nontrivial $D_g$ are translates of some subset $B$ of $\mathcal{H}$, then there is a set $\mathcal{A}$ of representatives of the nonidentity cosets of $\mathcal{G}/\mathcal{H}$ such that $D_a = B$ for all $a \in \mathcal{A}$. This in
turn implies that $\mathcal{D}$ can be written as $\mathcal{D} = \mathcal{A} + \mathcal{B} := \{a + b : a \in \mathcal{A}, b \in \mathcal{B}\}$, and in fact can be partitioned as $\mathcal{D} = \bigcup_{a \in \mathcal{A}} (a + \mathcal{B})$. This means the characteristic function of $\mathcal{D}$ factors as:

$$
\chi_{\mathcal{D}} = \sum_{a \in \mathcal{A}} \chi_{a+\mathcal{B}} = \sum_{a \in \mathcal{A}} \delta_a \ast \chi_{\mathcal{B}} = \left( \sum_{a \in \mathcal{A}} \delta_a \right) \ast \chi_{\mathcal{B}} = \chi_{\mathcal{A}} \ast \chi_{\mathcal{B}}.
$$

In the specific example above, $\mathcal{A} = \{1, 2, 8, 4\}$ and $\mathcal{B} = \{5, 10\}$. We now give such sets a name:

**Definition 4.1.** We say a difference set $\mathcal{D}$ for a finite abelian group $\mathcal{G}$ is **composite** if it is $\mathcal{H}$-fine for some subgroup $\mathcal{H}$ of $\mathcal{G}$—see Definition 3.1—and moreover there exist an $S$-element subset $\mathcal{A}$ of $\mathcal{G}$ and a difference set $\mathcal{B}$ such that $\mathcal{H} \cdot \mathcal{D} = \chi_{\mathcal{A}} \ast \chi_{\mathcal{B}}$.

Below, we show that the set $\mathcal{A}$ here is necessarily an $\mathcal{H}$-relative difference set (RDS) for $\mathcal{G}$ with particularly simple parameters. Here, recall that applying the quotient map $g \mapsto \overline{g}$ to any $\mathcal{H}$-RDS produces a difference set for $\mathcal{G}/\mathcal{H}$. As we shall see, quotienting the RDS $\mathcal{A}$ arising from a composite difference set yields $\mathcal{G}/\mathcal{H}\setminus \mathcal{B}$. For example, $\mathcal{A} = \{1, 2, 8, 4\}$ is a $\{0, 5, 10\}$-RDS for $\mathbb{Z}_{15}$ since its difference table is

|   | 1 | 2 | 8 | 4 |
|---|---|---|---|---|
| 1 | 0 | 14 | 8 | 12 |
| 2 | 1 | 0 | 9 | 13 |
| 8 | 7 | 6 | 0 | 4 |
| 4 | 3 | 2 | 1 | 10 |

and quotienting it by $\mathcal{H}$ yields the nonzero members of $\mathcal{G}/\mathcal{H} \cong \mathbb{Z}_5$. We further show that the cross-Gram matrices of the isometries (16) arising from a composite difference set have the remarkable property that their **triple products** are scalar multiples of the identity. For example, for the cross-Gram matrices (21) arising from $\mathcal{D} = \{6, 11, 7, 12, 13, 3, 9, 14\}$, we have $(E_0^*E_1)/(E_1^*E_2)/(E_2^*E_3)$ is:

$$
\frac{1}{8} \begin{bmatrix}
\omega & 0 & 0 & 0 \\
0 & \omega^2 & 0 & 0 \\
0 & 0 & \omega^8 & 0 \\
0 & 0 & 0 & \omega^4
\end{bmatrix} \begin{bmatrix}
\omega & 0 & 0 & 0 \\
0 & \omega^2 & 0 & 0 \\
0 & 0 & \omega^8 & 0 \\
0 & 0 & 0 & \omega^4
\end{bmatrix} = \frac{1}{8} \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}.
$$

As we shall see, this implies that the subspaces (12) arising from a composite difference set are more than equi-isoclinic, having orthogonal projection operators $\{P_n\}_{n \in \mathbb{N}}$ for which $P_n P_m P_n$ is always a scalar multiple of $P_{n_1} P_{n_2} P_{n_3}$.

**Theorem 4.2.** Assume $\mathcal{D}$ is a composite difference set for $\mathcal{G}$, and take $\mathcal{H}$, $\mathcal{A}$ and $\mathcal{B}$ as in Definition 3.1. For any $\gamma \in \hat{\mathcal{G}}$, define $E_{\gamma}$ as in (16) and let $\zeta_{\gamma} \in \mathbb{C}^\mathcal{B}$, $\zeta_{\gamma}(b) := \frac{\sqrt{2}}{\sqrt{\gamma}} \gamma(b)$. Then:

(a) $\mathcal{B}$ has cardinality $\frac{|\mathcal{D}|}{|\mathcal{H}|}$, and $\mathcal{A}$ is an RDS($S + 1, H, S, \frac{\mathcal{D} - 1}{|\mathcal{H}|}$) that is disjoint from $\mathcal{H}$.

Moreover, $G - D$ divides $D - 1$, and $G \leq 2D - 1$.

(b) $\mathcal{D}$ is an amalgam—see Definition 3.6—where $\mathcal{D}_a = \mathcal{H} \cap (\mathcal{D} - a) = \mathcal{B}$ for every $a \in \mathcal{A}$.

(c) The orthogonal projection operators $\{P_{\gamma}\}_{\gamma \in \hat{\mathcal{G}}/\mathcal{H}}$ onto the subspaces (12) satisfy

$$
\langle \zeta_{\gamma_1}, \zeta_{\gamma_2}, \zeta_{\gamma_3} \rangle P_{\gamma_1} P_{\gamma_2} P_{\gamma_3} = \langle \zeta_{\gamma_1}, \zeta_{\gamma_2}, \zeta_{\gamma_3} \rangle P_{\gamma_1} P_{\gamma_2} P_{\gamma_3}, \quad \forall \gamma_1, \gamma_2, \gamma_3 \in \hat{\mathcal{G}},
$$

where $|\langle \zeta_{\gamma}, \zeta_{\gamma'} \rangle| = \begin{cases} 
1, & \gamma = \gamma', \\
\frac{1}{\sqrt{|\mathcal{D}|}}, & \gamma \neq \gamma'.
\end{cases}$
Proof. For (a), recall from Section 2 that a \(D\)-element subset \(D\) of \(\mathcal{G}\) is an \(H\)-RDS for \(\mathcal{G}\) if and only if it satisfies (1); here, since \(A\) has cardinality \(S\) and \(G = H(S + 1)\), \(A\) is necessarily \(\frac{S(S-1)}{G-H} = \frac{S-1}{H}\) and \(A\) is an \(H\)-RDS for \(\mathcal{G}\) if and only if

\[
|(F^*\chi_A)(\gamma)|^2 = \begin{cases} 1, & \gamma \in H^+, \ \gamma \neq 1, \\ S, & \gamma \notin H^+. \end{cases}
\]  

(23)

To show this holds, note that since \(\chi_D = \chi_A \ast \chi_B\) we have \((F^*\chi_D)(\gamma) = (F^*\chi_A)(\gamma)(F^*\chi_B)(\gamma)\) for all \(\gamma \in \mathcal{G}\). Letting \(\gamma = 1\) gives \(D = S\#(B)\) and so \(B\) is a difference set for \(H\) of cardinality \(\frac{D}{S}\). Lemma \[\text{(a)}\] then gives that \(|(F^*\chi_B)(\gamma)|^2 = \frac{D^2}{S} S^3 G\) for any \(\gamma \notin H^+\). When combined with the fact from \[\text{(b)}\] that \(|(F^*\chi_D)(\gamma)| = \frac{D}{S}\) for all \(\gamma \neq 1\), this implies

\[
|(F^*\chi_A)(\gamma)|^2 = \frac{|(F^*\chi_D)(\gamma)|^2}{|(F^*\chi_D)(\gamma)|^2} = \frac{D^2}{S} \frac{S^3}{G^2} = S, \quad \forall \ \gamma \notin H^+.
\]

Meanwhile, the fact that \(B\) is a \(\frac{D}{S}\)-element subset of \(H\) implies \((F^*\chi_B)(\gamma) = \frac{D}{S}\) for any \(\gamma \in H^+\). As such, for any \(\gamma \in H^+, \ \gamma \neq 1\), combining this with Theorem \[\text{(c)}\] (ii) gives

\[
(F^*\chi_A)(\gamma) = \frac{(F^*\chi_D)(\gamma)}{(F^*\chi_B)(\gamma)} = -\frac{D}{S} \frac{S}{G} = -1.
\]

Thus, \[\text{(23)}\] indeed holds, meaning \(A\) is an \(S\)-element \(H\)-RDS for the group \(G\) of order \(G = H(S + 1)\). In particular, \(A\) is an RDS\((S + 1, H, S, \frac{D}{S-1})\). Moreover, \(A\) is disjoint from \(H\) since

\[
\mathcal{G}(\chi_H, \chi_A) = \mathcal{H}(F^*\chi_H, F^*\chi_A) = \langle \chi_{H^+}, F^*\chi_A \rangle = S + \sum_{\gamma \in H^+, \ \gamma \neq 1} (F^*\chi_A)(\gamma) = S + S(-1) = 0.
\]

Here, for any \(g \notin H\), the set \(\{(a, a') \in A \times A : g = a - a'\}\) has cardinality \(\frac{H}{S-1} = \frac{S^2 - 1}{G} = \frac{D-1}{G-D}\), and so \(G - D\) divides \(D - 1\). In particular, \(\frac{D-1}{D} \geq 1\) and so \(G \leq 2D - 1\).

For (b), note that since \(A\) is an \(H\)-RDS\((S + 1, H, S, \frac{D}{S-1})\) that is disjoint from \(H\), quotienting it by \(H\) yields an \(S\)-element difference set \(\mathcal{A} = \{a : a \in A\}\) for the group \(\mathcal{G}/H\) of order \(S + 1\) that does not contain \(\overline{1}\). Thus, \(\mathcal{A} = \mathcal{G}/H\{1\}\), and so \(A\) is a set of representatives of the nonidentity cosets of \(H\). Moreover, since \(\chi_D = \chi_A \ast \chi_B = \sum_{a \in A} \delta_a \ast \chi_B = \sum_{a \in A} \chi_{a + B}\), the set \(D\) can be partitioned as \(\sqcup_{a \in A} (a + B)\) where \(B\) is a subset of \(H\). This implies that for any \(g \notin H\), taking the unique \(a \in A\) such that \(g = a\), the above equation becomes \(D_g = B\).

For (c), note \(\{\zeta_\gamma\}_{\gamma \in \mathcal{G}}\) consists of \(S + 1\) copies of the harmonic ETF that arises from \(B\) being a difference set for \(H\). Indeed, \(\langle \zeta_\gamma, \zeta_\gamma' \rangle = \frac{S^2}{D^2} \sum_{b \in B} (\gamma^{-1} \gamma')(b) = \frac{S^2}{D^2} (F^*\chi_B)(\gamma \gamma')^{-1}\) for any \(\gamma, \gamma' \in \mathcal{G}\), and so Lemma \[\text{3.4}\] gives

\[
|\langle \zeta_\gamma, \zeta_\gamma' \rangle|^2 = \frac{S^2}{D^2} |(F^*\chi_B)(\gamma \gamma')^{-1}|^2 = \begin{cases} 1, & \gamma \gamma'^{-1} \in H^+, \\ \frac{1}{S^2}, & \gamma \gamma'^{-1} \notin H^+. \end{cases}
\]

18
Moreover, for any \( a \in \mathcal{A} \), we have \( \{d \in \mathcal{D} : d = \pi\} = a + \mathcal{D}_a = a + \mathcal{B} = \{a + b : b \in \mathcal{B}\} \). Combining these facts with Theorem 3.5(b), we find that for any \( \gamma, \gamma' \in \mathcal{G}, \mathbf{E}_{\gamma}^{*} \mathbf{E}_{\gamma'} \) is a diagonal matrix where

\[
(\mathbf{E}_{\gamma}^{*} \mathbf{E}_{\gamma'})(\pi, \pi) = \frac{S}{\sqrt{n}} \sum_{b \in \mathcal{B}} (\gamma^{-1} \gamma')(a + b) = \frac{S}{\sqrt{n}} (\gamma^{-1} \gamma')(a)(\mathbf{F}^{*} \chi_{\mathcal{B}})(\gamma(\gamma')^{-1}) = (\gamma^{-1} \gamma')(a)(\zeta_{\gamma}, \zeta_{\gamma'})
\]

for any \( a \in \mathcal{A} \). As such, for any \( \gamma_1, \gamma_2, \gamma_3 \in \mathcal{G}, \mathbf{E}_{\gamma_1}^{*} \mathbf{E}_{\gamma_2}, \mathbf{E}_{\gamma_3}^{*} \) are diagonal matrices whose \( \pi \)th diagonal entries are

\[
(\mathbf{E}_{\gamma_1}^{*} \mathbf{E}_{\gamma_2})(\pi, \pi) = (\gamma_3^{-1} \gamma_1)(a)(\gamma_1^{-1} \gamma_2)(a)(\zeta_{\gamma_3}, \zeta_{\gamma_1})(\zeta_{\gamma_1}, \zeta_{\gamma_2}),
\]

\[
(\mathbf{E}_{\gamma_2}^{*} \mathbf{E}_{\gamma_2})(\pi, \pi) = (\gamma_1^{-1} \gamma_2)(a)(\gamma_2^{-1} \gamma_3)(a)(\zeta_{\gamma_1}, \zeta_{\gamma_2})(\zeta_{\gamma_2}, \zeta_{\gamma_3}),
\]

respectively. Here, the \( a \)-dependent terms perfectly cancel, yielding

\[
\mathbf{E}_{\gamma_3}^{*} \mathbf{E}_{\gamma_1} \mathbf{E}_{\gamma_2} = |(\zeta_{\gamma_1}, \zeta_{\gamma_3})|^2 \mathbf{I}, \quad \mathbf{E}_{\gamma_1}^{*} \mathbf{E}_{\gamma_2} \mathbf{E}_{\gamma_2} \mathbf{E}_{\gamma_3} \mathbf{E}_{\gamma_4} = (\zeta_{\gamma_1}, \zeta_{\gamma_2}, \zeta_{\gamma_3}, \zeta_{\gamma_4}) \mathbf{I}.
\]

As such, right-multiplying the second equation by \( \frac{1}{(\zeta_{\gamma_3}, \zeta_{\gamma_1})} \mathbf{E}_{\gamma_4} \mathbf{E}_{\gamma_3} \) gives

\[
(\zeta_{\gamma_1}, \zeta_{\gamma_3}) \mathbf{E}_{\gamma_1}^{*} \mathbf{E}_{\gamma_2} \mathbf{E}_{\gamma_3} = (\zeta_{\gamma_1}, \zeta_{\gamma_2}, \zeta_{\gamma_3}, \zeta_{\gamma_4}) \mathbf{E}_{\gamma_4} \mathbf{E}_{\gamma_3}.
\]

as claimed. (The interested reader can verify that this single property actually implies both statements of (24) as special cases.) Moreover, since every \( \mathbf{E}_{\gamma}^{*} \mathbf{E}_{\gamma} = \mathbf{I} \), this equates to having

\[
(\zeta_{\gamma_1}, \zeta_{\gamma_3}) \mathbf{E}_{\gamma_1} \mathbf{E}_{\gamma_2} \mathbf{E}_{\gamma_3} \mathbf{E}_{\gamma_4} = (\zeta_{\gamma_1}, \zeta_{\gamma_2}, \zeta_{\gamma_3}) \mathbf{E}_{\gamma_4} \mathbf{E}_{\gamma_3},
\]

namingly to having (22). In the special case where \( \gamma_1 = \gamma_3 \neq \gamma_2 \), this reduces to the fact that (12) is an EITFF for \( \mathbb{C}^D \), as previously observed in Theorem 3.5(c).

There is a precedent for orthogonal projection operators that satisfy (22). To elaborate, from Section 2, recall that if \( \{\delta_m\}_{m \in \mathcal{M}} \) is an orthonormal basis for \( \mathbb{H} \) and for each \( m \in \mathcal{M} \), \( \{\varphi_n^{(m)}\}_{n \in \mathcal{N}} \) is any ETF\( (D, N) \) for \( \mathbb{K} \), then \( \{\mathcal{U}_n\}_{n \in \mathcal{N}}, \mathcal{U}_n := \text{span}\{\delta_m \otimes \varphi_n^{(m)}\}_{m \in \mathcal{M}} \) is an ETF for \( \mathbb{K} \otimes \mathbb{H} \). In the special case where these \( M \) ETFs are identical, we have that for any \( n \in \mathcal{N} \), the orthogonal projection operator onto \( \mathcal{U}_n \) is

\[
\mathbf{P}_n = \sum_{m \in \mathcal{M}} (\delta_m \otimes \varphi_n)(\delta_m \otimes \varphi_n)^* = \left( \sum_{m \in \mathcal{M}} \delta_m \delta_m^* \right) \otimes \varphi_n \varphi_n^* = \mathbf{I} \otimes \varphi_n \varphi_n^*.
\]

In particular, for any \( n_1, n_2, n_3 \in \mathcal{N} \),

\[
\mathbf{P}_{n_1} \mathbf{P}_{n_2} \mathbf{P}_{n_3} = \mathbf{I} \otimes (\varphi_{n_1} \varphi_{n_1}^* \varphi_{n_3} \varphi_{n_3}^*) = (\varphi_{n_1}, \varphi_{n_1}^*) \mathbf{I} \otimes \varphi_{n_3} \varphi_{n_3}^*),
\]

\[
\mathbf{P}_{n_1} \mathbf{P}_{n_2} \mathbf{P}_{n_3} = \mathbf{I} \otimes (\varphi_{n_1} \varphi_{n_2} \varphi_{n_2}^* \varphi_{n_3} \varphi_{n_3}^*) = (\varphi_{n_1}, \varphi_{n_2}^*) \mathbf{I} \otimes \varphi_{n_3} \varphi_{n_3}^*,
\]

and so \( (\varphi_{n_1}, \varphi_{n_3}) \mathbf{P}_{n_1} \mathbf{P}_{n_2} \mathbf{P}_{n_3} = (\varphi_{n_1}, \varphi_{n_2}) \mathbf{I} \otimes \varphi_{n_3} \varphi_{n_3}^* \mathbf{P}_{n_1} \mathbf{P}_{n_3} \). The similarity between this and (22) is not a coincidence. To explain, note that for any fine difference set, concatenating the matrices \( \{\mathbf{E}_{\gamma}\}_{\gamma \in \mathcal{G} / \mathcal{H}_1} \) from Theorem 3.5 over any choice of representatives of the cosets of \( \mathcal{H}_1 \) and then perfectly shuffling columns yields a \( D \times HS \) block-diagonal matrix, specifically an \( S \times S \) array of blocks of size \( \frac{n}{S} \times \mathcal{H} \). For example, applying this process to (20) yields an \( 8 \times 12 \) block diagonal matrix, namely a \( 4 \times 4 \) array whose four \( 2 \times 3 \) diagonal blocks are

\[
\begin{bmatrix}
1 & \omega^6 & \omega^{12} \\
1 & \omega^{11} & \omega^7
\end{bmatrix}, \quad
\begin{bmatrix}
1 & \omega^7 & \omega^{14} \\
1 & \omega^{12} & \omega^9
\end{bmatrix}, \quad
\begin{bmatrix}
1 & \omega^{13} & \omega^{11} \\
1 & \omega^3 & \omega^6
\end{bmatrix}, \quad
\begin{bmatrix}
1 & \omega^9 & \omega^3 \\
1 & \omega^{14} & \omega^{13}
\end{bmatrix}.
\]
Disregarding scalar multiples of columns, this is simply four copies of the harmonic ETF that arises from the difference set $B = \{5, 10\}$ for $H = \{0, 5, 10\}$. To see the degree to which this behavior holds in general, note that for any choice of representatives of the nonidentity cosets of $G/H$, dividing every column of $E_γ$ by the corresponding value of $γ(g)$ yields the matrix whose $(d, g)$th entry is

$$γ^{-1}(g)E_γ(d, g) = γ^{-1}(g)\frac{1}{\sqrt{D}} \begin{cases} γ(d), & d = g, \\ 0, & d ≠ g. \end{cases} = \frac{1}{\sqrt{D}} \begin{cases} γ(d - g), & d - g ∈ D_g, \\ 0, & d - g ∉ D_g. \end{cases}$$

Moreover, when $d - g ∈ D_g$, the fact that $D_g$ is a subset of $H$ implies that the value of $γ(d - g)$ only depends on the coset of $H'$ to which $γ$ belongs. At the same time, $G/H'$ is isomorphic to the dual of $H$ via the mapping that identifies $γ$ with the restriction of $γ$ to $H$. And, under this identification, the synthesis operator of the harmonic tight frame $\{φ_γ^{(g)}\}_{γ ∈ G/H'}$ that arises from regarding $D_g$ as a subset of $H$ is

$$Φ(g) ∈ ℂ^{D_g × G/H'}, \quad Φ(g)(hγ) := \frac{1}{\sqrt{D}}γ(h).$$

Comparing the previous two equations gives

$$γ^{-1}(g)E_γ(d, g) = \begin{cases} Φ(g)(d - g, γ), & d - g ∈ D_g, \\ 0, & d - g ∉ D_g. \end{cases}$$

As such, the union of the columns of $E_γ$ over any choice of representatives of the cosets of $G/H'$ is equivalent—via permutations and unimodular scalings—to a union of $\{δ_{γ} ⊗ φ_γ^{(g)}\}_{g ∈ G/H'}$ over any choice of representatives of the nonidentity cosets of $G/H$; here, $δ_γ$ is the $γ$th standard basis in the $S$-dimensional space $ℂ^{|G/H\{0\}|}$. Theorem 3.5 gives that (12) is an ETF for $ℂ^D$ if and only if each $D_g$ is a difference set for $H$, namely if and only if every $\{φ_γ^{(g)}\}_{γ ∈ G/H'}$ is an ETF for $ℂ^{D_g}$. It is therefore not surprising that the harmonic ETFs produced by Theorem 3.5 fail to disprove Conjecture 2.1 there are, in fact, disguised versions of the ETF construction that led to the conjecture in the first place.

In the special case that $D$ is composite, then taking our set of representatives of $G/H\{0\}$ to be $A$, the fact that $D_a = B$ for all $a ∈ A$ implies all $\{φ_γ^{(a)}\}_{γ ∈ G/H'}$ are equal, being the harmonic ETF arising from the difference set $B$. In this case, the union of the columns of $E_γ$ over any choice of representatives of the cosets of $G/H'$ is thus equivalent to a union of all tensor products of the standard basis of $ℂ^A$ with this harmonic ETF for $ℂ^B$. From this perspective, it is thus not surprising that an ETF that arises from a composite difference set obeys (22).

For example, since $D = \{6, 11, 7, 12, 13, 3, 9, 14\}$ is composite with $A = \{1, 2, 8, 4\}$, dividing the four columns of each $E_n$ in (20) by $\{ω^n, ω^{2n}, ω^{8n}, ω^{4n}\}$, respectively, and then concatenating and shuffling the resulting matrices yields a direct sum of four copies of the $2 × 3$ synthesis operator of the harmonic ETF that arises from $B = \{5, 10\}$ being a difference set for $H = \{0, 5, 10\}$, namely

$$Φ^{(1)} = Φ^{(2)} = Φ^{(3)} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & ω^5 & ω^{10} \\ 1 & ω^{10} & ω^5 \end{bmatrix}.$$ 

Here, it is simply a coincidence that the harmonic ETF arising from $B$ happens to itself be a regular simplex. Later on, we provide an explicit construction of a composite difference set where $B$ turns out to be the complement of an arbitrary Singer difference set.
4.2. Simplicial relative difference sets

From Theorem 3.5 we recall that any composite difference set $\mathcal{D}$ for $\mathcal{G}$ yields a relative difference set $\mathcal{A}$, specifically an RDS($S + 1, H, S, \frac{S - 1}{2}$) that is disjoint from $\mathcal{H}$. As we now explain, any relative difference set of this type has some remarkable properties, regardless of whether it arises from a composite difference set in this way. Here, quotienting such an RDS by $\mathcal{H}$ produces the difference set that consists of all $S$ nonidentity members of the group $\mathcal{G}/\mathcal{H}$ of order $S + 1$. That is, any such $\mathcal{A}$ is a set of representatives of the nonidentity cosets of $\mathcal{H}$. We give such sets a name:

**Definition 4.3.** Let $\mathcal{H}$ be a subgroup of a finite abelian group $\mathcal{G}$. A subset $\mathcal{A}$ of $\mathcal{G}$ is a simplicial $\mathcal{H}$-RDS if it is an $\mathcal{H}$-RDS for $\mathcal{G}$ that is also a set of representatives of the nonidentity cosets of $\mathcal{H}$. Equivalently, $\mathcal{A}$ is an $\mathcal{H}$-RDS($S + 1, H, S, \frac{S - 1}{2}$) that is disjoint from $\mathcal{H}$.

We remark that if $\mathcal{A}$ is a simplicial RDS for $\mathcal{G}$, then if $\mathcal{K}$ is any subgroup of the corresponding subgroup $\mathcal{H}$ of $\mathcal{G}$, then quotienting by $\mathcal{K}$ transforms the simplicial RDS($S + 1, H, S, \frac{S - 1}{2}$) into a simplicial RDS($S + 1, \frac{H}{\mathcal{K}}, \frac{S}{\mathcal{K}}(S - 1)$). Below we show that the harmonic tight frame arising from a simplicial RDS is comprised of regular simplices, and moreover, that these simplices are mutually unbiased in the quantum-information-theoretic sense. For example, extracting the rows of the character table of $\mathcal{G} = \mathbb{Z}_{15}$ indexed by members of the simplicial RDS $\mathcal{A} = \{1, 2, 8, 4\}$, and grouping the resulting normalized columns according to cosets of $\mathcal{H}^{\perp}$ gives

\[
[\Xi_0 \, \Xi_1 \, \Xi_2] = \frac{1}{\sqrt{3}} \begin{bmatrix}
\omega^0 & \omega^3 & \omega^6 & \omega^9 & \omega^{12} & \omega^1 & \omega^4 & \omega^7 & \omega^{10} & \omega^{13} & \omega^2 & \omega^5 & \omega^8 & \omega^{11} & \omega^{14} \\
\omega^0 & \omega^6 & \omega^{12} & \omega^3 & \omega^9 & \omega^2 & \omega^8 & \omega^{14} & \omega^5 & \omega^{11} & \omega^4 & \omega^{10} & \omega^7 & \omega^{13} \\
\omega^0 & \omega^{12} & \omega^9 & \omega^6 & \omega^3 & \omega^8 & \omega^2 & \omega^5 & \omega^{13} & \omega^7 & \omega^4 & \omega^{10} & \omega^1 & \omega^{14} \\
\end{bmatrix},
\]

namely three modulated versions of the regular 4-simplex whose synthesis operator $\Psi$ is given in (19). Here, any columns from distinct simplices have an inner product of modulus $\frac{1}{3}$.

Below, we further prove that every simplicial RDS for $\mathcal{G}$ yields a complex $\mathcal{G}/\mathcal{H}$-circulant conference matrix. In the special case where $\mathcal{A}$ is a simplicial RDS arising from a composite difference set, this construction reduces to a unimodular scalar multiple of the construction given in Theorem 3.5(d). However, as later examples will demonstrate, both this construction here and that of Theorem 3.5 are nontrivial generalizations of this common case, and each is capable of producing instances of circulant conference matrices that the other is not. Here, beginning with any simplicial RDS, such as $\mathcal{A} = \{1, 2, 8, 4\}$ for $\mathcal{G} = \mathbb{Z}_{15}$ for example, we modulate its characteristic function by a character of $\mathcal{G}$ that does not lie in $\mathcal{H}^{\perp}$, e.g. (0, $\omega$, $\omega^2$, 0, $\omega^4$, 0, 0, 0, $\omega^6$, 0, 0, 0, 0, 0, 0) where $\omega = e^{2\pi i/15}$. We then periodize this vector into one that is indexed by $\mathcal{G}/\mathcal{H}$, e.g. (0, $\omega$, $\omega^2$, $\omega^3$, $\omega$). As we prove below, this new vector is orthogonal to each of its translates. As such, the ($\mathcal{G} \times \mathcal{H}$)-circulant matrix with this vector as its first column, e.g.,

\[
\begin{bmatrix}
0 & \omega^4 & \omega^8 & \omega^2 & \omega \\
\omega & 0 & \omega^4 & \omega^8 & \omega^2 \\
\omega^2 & \omega & 0 & \omega^4 & \omega^8 \\
\omega^8 & \omega^2 & \omega & 0 & \omega^4 \\
\omega^4 & \omega^8 & \omega^2 & \omega & 0 \\
\end{bmatrix},
\]

is a conference matrix. Since this construction is valid for any character that does not lie in $\mathcal{H}^{\perp}$, we may, for example, raise each entry of the above matrix to any power not divisible by 3 to obtain another such matrix.
Theorem 4.4. Let $\mathcal{H}$ be a subgroup of a finite abelian group $G$. Let $A$ be a subset of $G$ with $\#(A) = S = \frac{\#(G)}{\#(\mathcal{H})}$. Let $\{\xi_\gamma\}_{\gamma \in H} \subseteq \mathbb{C}^A$, $\xi_\gamma(a) := \frac{1}{\sqrt{S}}\gamma(a)$. Then, the following are equivalent:

(i) $A$ is a simplicial $\mathcal{H}$-RDS for $G$; see Definition 4.3.
(ii) $(F^*\chi_A)(\gamma) = -1$ for all $\gamma \in H^\perp$, $\gamma \neq 1$ while $|(F^*\chi_A)(\gamma)| = \sqrt{S}$ for all $\gamma \notin H^\perp$.
(iii) For each $\gamma \in \hat{G}$, $(\xi_{\gamma'})_{\gamma' \in \gamma H^\perp}$ is a regular $S$-simplex whose vectors sum to zero, and moreover these simplices are mutually unbiased in the sense that $|(\xi_{\gamma}, \xi_{\gamma'})|$ is constant over all $\gamma \neq \gamma'$.

Moreover, in this case, $|\langle \xi_{\gamma}, \xi_{\gamma'} \rangle| = \frac{1}{\sqrt{S}}$ whenever $\gamma \neq \gamma'$, and for any $\gamma \notin H^\perp$,

$$C_\gamma \in \mathbb{C}^{G/\mathcal{H} \times G/\mathcal{H}}, \quad C_\gamma(\gamma, \gamma') := \sum_{\gamma \in A} \gamma(a),$$

is a circulant conference matrix. In the special case where $A$ arises from a composite difference set $D$ via Theorem 4.2 $C$ is a unimodular scalar multiple of the matrix $C$ constructed in Theorem 3.5(d).

Proof. Let $G = \#(G)$ and $H = \#(H)$. Since $S = \frac{G}{H} - 1$, we have $G = H(S + 1)$ and moreover $\frac{S(S-1)}{G-H} = \frac{S}{H}$. Thus, $A$ is an $\mathcal{H}$-RDS for $G$ if and only if it is an $\mathcal{H}$-RDS$(S+1, H, S, \frac{S}{H})$. Moreover, in this case, $\mathcal{H}$ and $\mathcal{H}$ thus give that $A$ is an $\mathcal{H}$-RDS if and only if

$$|(F^*\chi_A)(\gamma)|^2 = \begin{cases} 1, & \gamma \in H^\perp, \gamma \neq 1, \\ 0, & \gamma \notin H^\perp, \gamma \neq 1 \end{cases}, \quad \text{i.e.,} \quad |\langle \xi_{\gamma}, \xi_{\gamma'} \rangle| = \begin{cases} \frac{1}{\sqrt{S}}, & \gamma = \gamma', \gamma \neq \gamma', \\ 0, & \gamma \neq \gamma'. \end{cases}$$

Moreover, $A$ is disjoint from $\mathcal{H}$ if and only if

$$0 = G \langle H, \chi_A \rangle = \frac{1}{G} \langle F^*\chi_H, F^*\chi_A \rangle = \langle \chi_{H^\perp}, F^*\chi_A \rangle = S + \sum_{\gamma \in H^\perp, \gamma \neq 1} (F^*\chi_A)(\gamma).$$

In particular, $A$ is a simplicial $\mathcal{H}$-RDS if and only if it is an $\mathcal{H}$-RDS$(S+1, H, S, \frac{S}{H})$ that is disjoint from $\mathcal{H}$, namely if and only if it satisfies both (25) and (26).

(i $\iff$ ii) In light of the above facts, it suffices to prove that (ii) holds if and only if $A$ satisfies both (26) and (20). Here, (ii) immediate implies both (26) and (20). Conversely, if (26) and (20) hold, then $|(F^*\chi_A)(\gamma)| = \sqrt{S}$ for all $\gamma \notin H^\perp$ and moreover $\{ (F^*\chi_A)(\gamma) \}_{\gamma \in H^\perp, \gamma \neq 1}$ is a sequence of $S$ unimodular numbers that sum to $-S$, implying $(F^*\chi_A)(\gamma) = -1$ for all $\gamma \in H^\perp$, $\gamma \neq 1$.

(i $\iff$ iii) Again, it suffices to prove that (iii) holds if and only if $A$ satisfies both (25) and (20). Here, $(\xi_{\gamma'})_{\gamma' \in \gamma H^\perp}$ is a regular $S$-simplex for each $\gamma \in \hat{G}$ if and only if $|\langle \xi_{\gamma'}, \xi_{\gamma'} \rangle| = \frac{1}{S}$ for all $\gamma \neq \gamma'$ such that $\gamma = \gamma'$. Moreover, if a collection of regular $S$-simplices are mutually unbiased, that is, if $|\langle \xi_{\gamma}, \xi_{\gamma'} \rangle|$ is constant over all $\gamma, \gamma' \neq \gamma'$, then this constant is necessarily $\frac{1}{\sqrt{S}}$ since $\Xi \Xi^* = \frac{G}{S}I$,

$$\frac{G^2}{S} = \text{Tr}[(\Xi^2 I)^2] = \text{Tr}[(\Xi \Xi^*)^2] = \|\Xi^* \Xi\|^2_{Fro} = G[(1^2) + S(\frac{1}{S})^2] + \sum_{\gamma \in \gamma \neq \gamma' \neq \gamma} |\langle \varphi_{\gamma}, \varphi_{\gamma'} \rangle|^2,$$

implying the average value of $|\langle \varphi_{\gamma}, \varphi_{\gamma'} \rangle|^2$ over all $G(G-S-1)$ choices of $\gamma \neq \gamma'$, $\gamma \neq \gamma'$ is $\frac{1}{S}$:

$$\frac{1}{G(G-S-1)} \sum_{\gamma \in \gamma} \sum_{\gamma' \neq \gamma} |\langle \varphi_{\gamma}, \varphi_{\gamma'} \rangle|^2 = \frac{1}{G(G-S-1)}[\frac{G^2}{S} - \frac{G(S+1)}{S}] = \frac{1}{S}.$$
In particular, (25) holds if and only if \( \{ \{ x \gamma \} \}_{\gamma \in H^\perp} \) is a collection of \( H \) mutually unbiased regular \( S \)-simplices. Meanwhile (26) equates to each \( \{ x \gamma \} \}_{\gamma \in H^\perp} \) summing to zero: for any \( \gamma \in \mathcal{G} \),

\[
\sum_{\gamma \in H^\perp} x \gamma(a) = \frac{1}{|\mathcal{F}|} \sum_{\gamma \in H^\perp} \gamma(a) \gamma'(a) = \frac{1}{|\mathcal{F}|} \gamma(a) (\mathcal{F} x H^\perp)(a) = \frac{1}{|\mathcal{F}|} \gamma(a)^{G/H}(a)
\]

is zero for all \( a \in A \) if and only if \( A \) is disjoint from \( H \), namely if and only if (26) holds.

For the final conclusions, now assume \( A \) is a simplicial \( H \)-RDS, take any \( \gamma \notin H^\perp \), and define \( \hat{C}_\gamma \) as in the statement of the result. When \( \overline{\gamma} = \overline{\gamma} \), the fact that \( A \) is disjoint from \( H \) means \( \{ a \in A : \overline{a} = \overline{\gamma} - \overline{\gamma} \} = \{ a \in A : a \in H \} \) is empty, and so every diagonal entry of \( \hat{C}_\gamma \) is 0. Meanwhile, if \( \overline{\gamma} = \overline{\gamma'} \), the fact that \( A \) is a set of representatives of the nonidentity cosets of \( H \) implies that \( \{ a \in A : \overline{a} = \overline{\gamma} - \overline{\gamma} \} \) is a singleton set, meaning \( \hat{C}_\gamma(\overline{\gamma}, \overline{\gamma'}) \) is unimodular, being a “sum” of a single unimodular number. As such, all that remains to be seen is that \( \hat{C}/\hat{C} = S I \). Here, \( (\hat{C} \hat{C}_\gamma(\overline{\gamma}, \overline{\gamma'})) = (\hat{y}_\gamma \ast \hat{y}_\gamma)(\overline{\gamma} - \overline{\gamma'}) \), where \( \hat{y}_\gamma \in \mathbb{C}^{|\mathcal{F}|/|H|} \) is the first column of \( \hat{C} \), defined by \( y_\gamma(\overline{\gamma}) \) being 0 whenever \( \overline{\gamma} = \overline{\gamma} \), and as being \( \gamma(a) \) whenever \( \overline{\gamma} \neq \overline{\gamma} \), where \( a \) is the unique member of \( A \) such that \( \overline{a} = \overline{\gamma} \). It thus suffices to show that \( \hat{y}_\gamma \ast \hat{y}_\gamma = S \delta_{\overline{\gamma}} \). Taking Fourier transforms over the group \( G/H \), this further equates to having \( |(\mathcal{F}^* \hat{G}/H \mathcal{Y}_\gamma)(\gamma')|^2 = S \) for all \( \gamma' \) in the dual of \( G/H \) which, as noted in Section 2, is naturally identified with \( H^\perp \). This is indeed the case: for any \( \gamma' \in H^\perp \),

\[
(\mathcal{F}^* \hat{G}/H \mathcal{Y}_\gamma)(\gamma') = \sum_{\overline{\gamma} \in \mathcal{G}/H} (\gamma')^{-1}(g) y_\gamma(\overline{\gamma}) = \sum_{a \in A} (\gamma')^{-1}(a) \gamma(a) = (\mathcal{F}^* \hat{X}_A)(\gamma^{-1} \gamma'),
\]

and combining this with (26) and the fact that \( \gamma \notin H^\perp \) gives \( |(\mathcal{F}^* \hat{G}/H \mathcal{Y}_\gamma)(\gamma')|^2 = S \).

In the special case where \( A \) is an RDS that arises from a composite difference set in the manner of Theorem 4.2(a), then for any \( g \notin H \), taking the unique \( a \in A \) such that \( \overline{a} = \overline{\gamma} \), we have \( \{ a' \in A : \overline{a} = \overline{\gamma} \} = \{ a \} \) while Theorem 4.2(b) gives \( \{ d \in D : \overline{d} = \overline{\gamma} \} = a + D_a = a + B \). As such, for any \( \overline{\gamma} \neq \overline{\gamma'} \), the construction of the circulant conference matrix \( C_\gamma \) of Theorem 5.5(d) reduces to

\[
C_\gamma(\overline{\gamma}, \overline{\gamma'}) = \frac{s^d}{D} \sum_{d \in D} \gamma(d) = \frac{s^d}{D} \sum_{d \in D} \gamma(a + b) = [ \frac{s^d}{D} \mathcal{F}^* (\hat{X}_B)(\gamma^{-1}) ] \gamma(a) = z C_\gamma(\overline{\gamma}, \overline{\gamma'})
\]

where \( z = [ \frac{s^d}{D} \mathcal{F}^* (\hat{X}_B)(\gamma^{-1}) ] \) is constant over all \( \overline{\gamma} \neq \overline{\gamma}' \). Since every diagonal entry of both \( C_\gamma \) and \( \hat{C}_\gamma \) is zero, this implies \( C_\gamma = z C_\gamma \) where \( |z| = 1 \) by Lemma 3.4.

4.3. Constructions of finite difference sets, composite difference sets and amalgams

We now discuss how the known finite difference sets from \[13\] fit into the framework discussed here. We shall see that some finite difference sets are amalgams while others are not, and that some amalgams are composite difference sets while others are not.

4.3.1. Singer difference sets

For any prime power \( q \), let \( \mathbb{F}_q \) denote the finite field of order \( q \) and let \( \mathbb{F}_{q^j}^* \) denote its multiplicative group, which is well known to be cyclic. For any integer \( J \geq 2 \), let \( \text{tr}_{Q^j/q} : \mathbb{F}_{q^j} \to \mathbb{F}_q \), \( \text{tr}_{Q^j/q}(x) := \sum_{j=0}^{J-1} x^{q^j} \) be the field trace, which is a well-known, nontrivial linear functional of \( \mathbb{F}_{q^j} \), regarded as a \( J \)-dimensional vector space over the field \( \mathbb{F}_q \). In this setting, the affine hyperplane \( \mathcal{E} = \{ x \in \mathbb{F}_{q^j}^* : \text{tr}_{Q^j/q}(x) = 1 \} \) is a well-known RDS for the cyclic group \( \mathcal{G} = \mathbb{F}_{q^j}^* \) of order
$Q^J - 1$ \cite{35}. Here, the sets $\{x \in \mathbb{F}_Q^\times : x \in \mathbb{F}_{Q^J}^\times\}$ are the distinct affine hyperplanes of $\mathbb{F}_{Q^J}$ that do not contain 0. The affine hyperplanes $\mathcal{E}$ and $x \mathcal{E}$ are equal if and only if $x = 1$, and are parallel if and only if $x \in \mathbb{F}_Q^\times, x \neq 1$. In any other case, these two affine hyperplanes intersect in an affine subspace of codimension 2. Thus, for any $x \in \mathbb{F}_Q^\times$,

$$\#(\mathcal{E} \cap (x \mathcal{E})) = \begin{cases} Q^{J-1}, & x = 1, \\ 0, & x \in \mathbb{F}_Q^\times, y \neq 1, \\ Q^{J-2}, & x \neq \mathbb{F}_Q^\times. \end{cases}$$

As such, letting $K = \mathbb{F}_Q^\times$, $\mathcal{E}$ is a $K$-RDS($Q^{J-1}/Q^J, Q - 1, Q^{J-1}, Q^{J-2}$) for $\mathcal{G}$. Quotienting by $K$ thus produces a $Q^{J-1}$-element difference set $\overline{\mathcal{E}} = \{x \in \mathbb{F}_{Q^J}^\times/\mathbb{F}_Q^\times : \text{tr}_{Q^J/Q}(x) \neq 0\}$ for $\mathcal{G}/K = \mathbb{F}_{Q^J}^\times/\mathbb{F}_Q^\times$; the complement of $\overline{\mathcal{E}}$ is the classical Singer difference set. When $J \geq 4$ is even, a shift of this difference set is known to be fine \cite{18}. Below, we show that this fine difference set is in fact composite, and the RDS from which it arises is part of a larger family of RDSs to which Theorem 4.4 applies.

To elaborate, in the special case where $J = 2$, the aforementioned construction reduces to

$$\mathcal{E} = \{x \in \mathbb{F}_{Q^2}^\times : \text{tr}_{Q^2/Q}(x) = x + x^Q = 1\}$$

being a $K$-RDS($Q + 1, Q - 1, Q, 1$) for $\mathcal{G} = \mathbb{F}_Q^\times$, where $K = \mathbb{F}_Q^\times$. Since quotienting $\mathcal{E}$ by $K$ produces a $Q$-element difference set $\overline{\mathcal{E}}$ for the group $\overline{\mathcal{G}}/K$ of order $Q + 1$, we can always shift $\overline{\mathcal{E}}$ if necessary so that its quotient avoids $\{0\}$, that is, so that $\overline{\mathcal{E}}$ is disjoint from $K$. In fact, when $Q$ is even, no shift is necessary: every $x \in \mathbb{F}_Q$ satisfies $x^Q = x$ and so $\text{tr}_{Q^2/Q}(x) = x + x^Q = x + x = 0$, implying $K$ is disjoint from $\mathcal{E}$. Moreover, when $Q$ is odd, such a shift can be computed explicitly: letting $K = \mathbb{F}_Q^\times$, $\beta = \alpha^{-(Q+1)/2}$ satisfies $\beta^{Q-1} = \alpha^{-(Q^2-1)/2} = -1$; as such, $\text{tr}_{Q^2/Q}(\beta x) = (\beta x) + (\beta x)^Q = \beta(x - x^Q)$ for all $x \in \mathbb{F}_Q^\times$ implying

$$\alpha^{(Q+1)/2}\mathcal{E} = \beta^{-1}\mathcal{E} = \{x \in \mathbb{F}_{Q^2}^\times : \text{tr}_{Q^2/Q}(\beta x) = 1\} = \{x \in \mathbb{F}_{Q^2}^\times : x - x^Q = 1\}$$

is a $K$-RDS for $\mathcal{G}$ that is disjoint from $K = \mathbb{F}_Q^\times = \{x \in \mathbb{F}_{Q^2}^\times : x - x^Q = 0\}$.

Regardless, for any prime power $Q$, we see that there exists a $K$-RDS($Q + 1, Q - 1, Q, 1$) that is disjoint from $K$, namely an RDS that is simplicial in the sense of Definition \cite{13} by Theorem \cite{13}(iii), the corresponding $(Q^2 - 1)$-vector harmonic tight frame is a union of $Q + 1$ mutually unbiased regular $Q$-simplices. Theorem \cite{13} also yields a circulant conference matrix of order $Q + 1$. As we next explain, some quotients of some RDSs of this type naturally arise from composite difference sets in the manner of Theorem 4.2.

Here, for any prime power $Q$ and $J \geq 2$, we consider the Singer-complement difference set that arises from an affine hyperplane in a $2J$-dimensional extension of $\mathbb{F}_Q$, namely

$$\mathcal{D} = \{x \in \mathbb{F}_Q^{2J} : \text{tr}_{Q^2/J}(x) \neq 0\}$$

where $\text{tr}_{Q^2/J}(x) = \sum_{j=0}^{2J-1} x^Q$. Such difference sets constitute “half” of all Singer-complement difference sets. As noted in \cite{18}, the remaining “half” of these difference sets—that arise in odd-dimensional extensions of $\mathbb{F}_Q$—do not seem to be fine in general, and in fact cannot be fine when $Q$ is an odd power of a prime since in such cases $S$ is not an integer. From above, we know that $\mathcal{D}$ is a difference set of cardinality $D = Q^{2J-1}$ for the cyclic group $\mathcal{G} = \mathbb{F}_{Q^J}/\mathbb{F}_Q$ of order $G = Q^{2J-1}/Q^J$. It follows that

$$G - 1 = Q^{2J-1}/Q^J, \quad G - D = \frac{Q^{2J-1}}{Q^J}, \quad S := \frac{D(G-1)}{G-D} = Q^J, \quad H := \frac{G}{S+1} = \frac{Q^{2J-1}}{Q^J-1}.$$
For $\mathcal{D}$ to be fine, it must be disjoint from a subgroup $\mathcal{H}$ of $\mathcal{G}$ of order $H$. (To be precise, we shall see that there is always a shift of $[28]$ for which this occurs.) Since $\mathcal{G}$ is cyclic and $S+1$ divides $G$, there is exactly one such subgroup, namely $\mathcal{H} = \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q$. If $\mathcal{D}$ is composite, Theorem 4.2(a) implies that it factors in terms of an $\mathcal{H}$-RDS with parameters $(S+1, H, S, S^{-1}) = (Q^J + 1, Q^{-1}, Q^J, Q - 1)$. There is a natural candidate for such an RDS: taking “$Q$” in (27) to be $\mathbb{F}^x_Q$ to be $Q^J$ gives that

$$\{x \in \mathbb{F}^x_{QJ}: \text{tr}_{Q^J}QJ(x) = 1\}$$

is a $K$-RDS($Q^J + 1, Q^J - 1, Q^J, 1$) where $K = \mathbb{F}^x_{QJ}$: quotiening this by $\mathbb{F}^x_Q$ produces an $\mathcal{H}$-RDS with the desired parameters, namely

$$\mathcal{A} = \{\pi \in \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q : \exists y \in x\mathbb{F}^x_Q \text{ s.t.} \text{tr}_{Q^J}QJ(y) = 1\} = \{\pi \in \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q : \text{tr}_{Q^J}QJ(x) \in \mathbb{F}^x_Q\}.$$  

Further recall from Theorem 4.2 that when $\mathcal{D}$ is composite, we expect $\mathcal{D}_a = \mathcal{H} \cap (a^{-1}\mathcal{D}) = \mathcal{B}$ for all $a \in \mathcal{A}$. Here, for any $a \in \mathcal{A}$, writing $a = \pi$ where $y \in \mathbb{F}^x_{QJ}$ satisfies $\text{tr}_{Q^J}QJ(y) \in \mathbb{F}^x_Q$, we have

$$\mathcal{D}_a = (\mathbb{F}^x_Q/\mathbb{F}^x_Q) \cap \{y^{-1}\pi \in \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q : \text{tr}_{Q^J}QJ(x) \neq 0\}$$

$$= \{y^{-1}x \in \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q : \text{tr}_{Q^J}QJ(x) \neq 0\}$$

$$= \{\pi \in \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q : \text{tr}_{Q^J}QJ(yz) \neq 0\}. \quad (30)$$

To continue simplifying this, we recall from finite field theory that finite field traces factor over intermediate fields: the *freshman’s dream* implies that for any $x \in \mathbb{F}^{QJ}$

$$\text{tr}_{Q^J}(\text{tr}_{Q^J}QJ(x)) = \text{tr}_{Q^J}QJ(1 + xQ^J) = \sum_{j=0}^{J-1} (1 + xQ^j)Q^j = \sum_{j=0}^{J-1} (1 + xQ^{j+1}) = \text{tr}_{Q^J}QJ(x).$$

When combined with the fact that $\text{tr}_{Q^J}QJ(y) \in \mathbb{F}^x_Q$, and the fact that $\text{tr}_{Q^J}QJ$ is linear in $QJ$ while $\text{tr}_{Q^J}QJ$ is linear in $\mathbb{F}^x_Q$, this implies that for any representative $z \in \mathbb{F}^x_{QJ}$ of a coset $\pi \in \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q$,

$$\text{tr}_{Q^J}QJ(yz) = \text{tr}_{Q^J}QJ(\text{tr}_{Q^J}QJ(yz)) = \text{tr}_{Q^J}QJ(\text{tr}_{Q^J}QJ(y)) = \text{tr}_{Q^J}QJ(\text{tr}_{Q^J}QJ(z)).$$

When taken together with the fact that $\text{tr}_{Q^J}QJ(y) \neq 0$, this simplifies (30) as

$$\mathcal{D}_a = \{\pi \in \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q : [\text{tr}_{Q^J}QJ(\pi)][\text{tr}_{Q^J}QJ(z)] \neq 0\} = \{\pi \in \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q : \text{tr}_{Q^J}QJ(\pi) \neq 0\}. \quad (31)$$

That is, for every $a \in \mathcal{A}$, we have $\mathcal{D}_a = \mathcal{B}$ where $\mathcal{B} = \{\pi \in \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q : \text{tr}_{Q^J}QJ(\pi) \neq 0\}$ is, by definition, the complement of the canonical Singer difference set in the group $\mathcal{H} = \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q$. Here, the fact that $\mathcal{A}$ is an $\mathcal{H}$-RDS for $\mathcal{G}$ while $\mathcal{B}$ is a subset of $\mathcal{H}$ implies that the sets $\{a\mathcal{B}\}_{a \in \mathcal{A}}$ are disjoint. As such, for each $a \in \mathcal{A}$ we have $a\mathcal{B} = a\mathcal{D}_a = \mathcal{D} \cap (a\mathcal{H}) \subseteq \mathcal{D}$. Thus, $\mathcal{D}$ contains the disjoint union $\cup_{a \in \mathcal{A}} a\mathcal{B}$. Moreover, as the cardinality of $\cup_{a \in \mathcal{A}} a\mathcal{B}$ is $\#(\mathcal{A})\#(\mathcal{B}) = Q^J(Q^{J-1}) = Q^{2J-1} = \#(\mathcal{D})$, $\mathcal{D}$ is this disjoint union, meaning $\mathcal{X}_D = \mathcal{X}_A \times \mathcal{X}_B$ where $\mathcal{A}$ has cardinality $S = Q^J$.

Comparing this against Definition 4.1 all that remains to be shown is that $\mathcal{D}$ is fine, namely that it is disjoint from $\mathcal{H} = \mathbb{F}^x_{QJ}/\mathbb{F}^x_Q$. Though this is not always the case, it is always possible to shift $\mathcal{D}$ so as to gain this property without losing the others. In fact, since $\mathcal{X}_D = \mathcal{X}_A \times \mathcal{X}_B$ where $\mathcal{B}$ is a subset of $\mathcal{H}$ and where $\mathcal{A}$ is obtained by quotienting (29) by $\mathbb{F}^x_Q$, it suffices to shift (29) so that it becomes disjoint from $\mathbb{F}^x_{QJ}$. We have already seen how to do this: no shift is necessary when $Q$ is even, and when $Q$ is odd, we can multiply (29) by $\alpha^{(Q^J+1)/2}$ where $\alpha$ is a generator of $\mathbb{F}^x_{QJ}$. We summarize these facts as follows:
Theorem 4.5. For any prime power $Q$, the classical RDS \((21)\) can be shifted to produce a simplicial RDS\((Q+1, Q−1, Q, 1)\). Moreover, for any \(J \geq 2\), the complement of the Singer difference set in the cyclic group \(G\) of order \(\frac{Q^J−1}{Q−1}\) can be shifted so as to produce a \(Q^{J−1}\)-element composite difference set \(D\) for \(G\), and the resulting factors \(A\) and \(B\) are a simplicial RDS\((Q^{J+1}, Q^{J−1}, Q, Q−1)\) and the complement of the Singer difference set for \(\frac{Q^J−1}{Q−1}\)-element subgroup \(H\) of \(G\), respectively.

For any prime power \(Q\) and \(J ≥ 2\), applying Theorem 4.2 to these composite difference sets yields an EITFF whose orthogonal projection operators satisfy \((22)\), and also recovers the underlying RDS\((Q^J + 1, Q^J−1, Q^J, Q−1)\). Applying Theorem 4.4 to these RDSs produces \(\frac{Q^J−1}{Q−1}\) mutually unbiased regular \(Q^J\)-simplices as well as circulant conference matrices of size \(Q^J + 1\). In the special case where \(Q = 2\), \(J = 2\), this construction yields the composite difference set for \(\mathbb{F}_2^x \cong \mathbb{Z}_{15}\) given in Example 3.2 and the resulting conference matrices are given in Example 3.7. Meanwhile, applying Theorem 4.4 directly to the (suitably shifted) version of the RDS\((Q+1, Q−1, Q, 1)\) given in \((21)\) gives \(Q − 1\) mutually unbiased regular \(Q\)-simplices as well as circulant conference matrices of size \(Q + 1\). This latter construction is more general, as it is the only one that yields circulant conference matrices of size \(P + 1\) where \(P\) is prime. We note that a harmonic tight frame appearing from this RDS\((Q+1, Q−1, Q, 1)\) has recently appeared elsewhere in the frame literature: concatenating it with the standard basis yields tight frames that achieve the orthoplex bound, and also provide an alternative solution to a reconstruction problem in quantum information theory that is usually solved with mutually unbiased bases [6].

The fact that complements of Singer difference sets factor in this way is not new. Indeed, it is the fundamental idea behind the now-classical method of Gordon, Mills and Welch for producing many nonequivalent difference sets with Singer-complement parameters [26, 33]. In fact, every known example of an RDS either quotients to the entire group or has parameters that match those of the complement of a Singer difference set [35], namely \((G, H, D, \Lambda)\) where \(G = \frac{Q^J−1}{Q−1}\), \(D = Q^{J−1}\) and \(H \Lambda = Q^{J−2}(Q−1)\). In light of Theorem 4.2(a), it is therefore not too surprising that these are the only composite difference sets we have discovered so far.

4.3.2. Twin prime power difference sets

For any odd prime power \(Q\), let \(S_Q := \{x^2 : x \in \mathbb{F}_Q^x\}\) and let \(N_Q := \mathbb{F}_Q^x \setminus S_Q\) be the nonzero squares and nonsquares in \(\mathbb{F}_Q\), with both sets having cardinality \(\frac{1}{2}(Q−1)\). When \(Q\) and \(Q + 2\) are both powers of an odd prime, the set

\[
D = ([0] \times \mathbb{F}_{Q+2}^x) \sqcup (S_Q \times N_{Q+2}) \sqcup (N_Q \times S_{Q+2})
\]

(31)

is a difference set for \(G = \mathbb{F}_Q \times \mathbb{F}_{Q+2}\) of cardinality \(D = Q + 1 + 2\frac{1}{2}(Q−1)(Q+1) = \frac{1}{2}(Q+1)^2\)

being the complement of \((\mathbb{F}_Q \times \{0\}) \sqcup (S_Q \times S_{Q+2}) \sqcup (N_Q \times N_{Q+2})\), which is the well-known twin prime power difference set for \(G\). Here \(G = Q(Q + 2)\) and so

\[
G − 1 = Q^2 + 2Q − 1, \quad G − D = \frac{1}{2}(Q^2 + 2Q − 1), \quad S := \left[ \frac{D(G−1)}{G−D} \right]^\frac{1}{2} = Q + 1, \quad H := \frac{G}{S+1} = Q,
\]

and so \(D\) is fine, being disjoint from the subgroup \(H = \mathbb{F}_Q \times \{0\}\) of order \(H \cong 18\). By Theorem 3.3 every nonidentity coset of \(H\) thus intersects \(D\) in exactly \(\frac{S}{2} = \frac{1}{2}(Q + 1)\) points. This fine difference set can only be an amalgam if the necessary condition of Theorem 3.5(c) is met, namely only if \(S^3 = (Q + 1)^3\) divides \(D^2 = \frac{1}{4}(Q + 1)^4\), that is, only if \(Q \equiv 3\) mod 4. Here, it is notable that \(\frac{Q^2−1}{Q−1} = 1\) regardless of whether \(Q\) is congruent to 1 or 3 modulo 4. That is, even though every
composite difference set is an amalgam, there are at least some cases in which the necessary condition on composite difference sets given in Theorem 4.2(a) does not imply the necessary condition on amalgams given in Theorem 3.3(c). Put another way, in order for a composite difference set to exist, both $\frac{D^2}{2\pi}$ and $\frac{D-1}{D}$ are necessarily integers.

When $Q \equiv 3 \mod 4$, we claim that $D$ is an amalgam. Since $D$ is disjoint from $H$, it suffices to show that for all $g \not\in \mathcal{H}$, $D_g = \mathcal{H} \cap (D - g)$ is a difference set for $\mathcal{H}$. Here, any $g \not\in \mathcal{H} = \mathbb{F}_Q \times \{0\}$ is of the form $g = (x, y)$ where $y \neq 0$ and so

$$D - g = \left[\{-x\} \times (\mathbb{F}_{Q+2}^\times - y)\right] \cup \left[(\mathcal{S}_Q - x) \times (\mathcal{N}_{Q+2} - y)\right] \cup \left[(\mathcal{N}_Q - x) \times (\mathcal{S}_{Q+2} - y)\right].$$

When $y \in \mathcal{S}_{Q+2}$, the intersection of $D - g$ with $\mathcal{H} = \mathbb{F}_Q \times \{0\}$ is thus

$$D_g = \left[\{-x\} \times \{0\}\right] \cup \left[(\mathcal{N}_Q - x) \times \{0\}\right] = (\mathbb{F}_Q \setminus \mathcal{S}_Q - x) \times \{0\},$$

which is a difference set for $\mathcal{H}$, since $\mathbb{F}_Q \setminus \mathcal{S}_Q - x$ is a difference set for $\mathbb{F}_Q$, being a shift of the complement of the difference set $\mathcal{S}_Q$. Similarly, when $y \in \mathcal{N}_{Q+2}$,

$$D_g = \left[\{-x\} \times \{0\}\right] \cup \left[(\mathcal{S}_Q - x) \times \{0\}\right] = (\mathbb{F}_Q \setminus \mathcal{N}_Q - x) \times \{0\},$$

which is also a difference set for $\mathcal{H}$. Overall, we see that $D$ is an amalgam when $Q \equiv 3 \mod 4$.

However, as we now explain, $D$ is not composite in general since $\mathbb{F}_Q \setminus \mathcal{S}_Q$ and $\mathbb{F}_Q \setminus \mathcal{N}_Q$ are only shifts of each other when $Q = 3$. Indeed, when $Q = 3$, $\mathbb{F}_3 \setminus \mathcal{S}_3 = \{0, 2\}$ and $\mathbb{F}_3 \setminus \mathcal{N}_3 = \{0, 1\}$ are shifts of each other, and so in this case, (31) becomes the composite difference set

$$\{(0, 1), (0, 2), (0, 3), (0, 4)\} \cup \{(1, 2), (1, 3)\} \cup \{(2, 1), (2, 4)\}$$

for $\mathbb{Z}_3 \times \mathbb{Z}_5$. Inverting the isomorphism $1 \mapsto (1, 1)$ gives an alternative construction of the composite difference set $\{6, 12, 3, 9, 7, 13, 11, 14\}$ for $\mathbb{Z}_{15}$ given in Example 3.2.

Meanwhile, for any $Q \neq 3$, $\mathcal{S}_Q$ and $\mathcal{N}_Q$ are not shifts of each other meaning (31) is an amalgam that is not a composite difference set. For an elementary proof of this fact, take any prime power $Q$ and suppose that there exists $x \in \mathbb{F}_Q$ such that $\mathcal{N}_Q = \mathcal{S}_Q + x$. Here, $\mathcal{S}_Q$ and $\mathcal{N}_Q$ partition $\mathbb{F}_Q^\times$ into two sets of cardinality $\frac{Q}{2}(Q - 1)$. Specifically, $\mathcal{S}_Q$ and $\mathcal{N}_Q$ are the even and odd powers, respectively, of any generator $\alpha$ of $\mathbb{F}_Q^\times$. As such, we cannot have $x = 0$, and moreover if $x \in \mathcal{N}_Q$ then dividing $\mathcal{N}_Q = \mathcal{S}_Q + x$ by $x$ gives $\mathcal{S}_Q = \mathcal{N}_Q + 1$; since $1 = 1^2 \in \mathcal{S}_Q$, this implies $0 \in \mathcal{S}_Q - 1 = \mathcal{N}_Q$, a contradiction. Thus, $x \in \mathcal{S}_Q$, and dividing $\mathcal{N}_Q = \mathcal{S}_Q + x$ by $x$ gives $\mathcal{N}_Q = \mathcal{S}_Q + 1$. This fact is thus also true for any divisor $Q'$ of $Q$: when $\mathbb{F}_{Q'}^\times \subseteq \mathbb{F}_Q^\times$ we have $\mathcal{S}_{Q'} \subseteq \mathcal{S}_Q$ and so $\mathcal{S}_Q + 1 \subseteq \mathcal{S}_{Q'} + 1 = \mathcal{N}_{Q'} \subseteq \mathcal{N}_Q'$; since both $\mathcal{S}_{Q'}$ and $\mathcal{N}_{Q'}$ have cardinality $\frac{1}{2}(Q' - 1)$, this implies $\mathcal{N}_{Q'} = \mathcal{S}_Q + 1$. This in turn implies that $Q$ is prime: if not, letting $Q' = P^2$ where $Q = P^J$ for some $J \geq 2$, we have $P^2 \equiv 1 \mod 4$, and so $-1 = \beta(P^2 - 1)/2 = (\beta(P^2 - 1)/4)^2$ for any generator $\beta$ of $\mathbb{F}_{P^2}^\times$; thus $0 \in \mathcal{S}_{P^2} + 1 = \mathcal{N}_{P^2}$, a contradiction. Moreover, when $Q = P$ is prime, we necessarily have that $P \equiv 3 \mod 4$ or else $-1 \in \mathcal{S}_P$, implying $0 \in \mathcal{N}_P$, a contradiction. To summarize our progress so far, if $\mathcal{S}_Q$ and $\mathcal{N}_Q$ are shifts of each other, then $Q$ is necessarily some prime $P \equiv 3 \mod 4$, and $\mathcal{N}_P = \mathcal{S}_P + 1$. In particular, this implies that every square modulo $P$ is followed by a nonsquare modulo $P$. Since $\mathcal{S}_P$ and $\mathcal{N}_P$ partition $\mathbb{F}_P^\times = \{1, 2, \ldots, P - 1\}$, this is only possible if $\mathcal{S}_P = \{1, 3, \ldots, P - 2\}$ and $\mathcal{N}_P = \{2, 4, \ldots, P - 1\}$ are the odd and even numbers modulo $P$, respectively. As we have already seen, this all indeed happens in the special case where $P = 3$. However, it fails for all greater primes since $4 = 2^2$ is a square.

We summarize these facts as follows:
Theorem 4.6. Let $Q$ and $Q + 2$ be odd twin prime powers, and let $D$ be the \( \frac{1}{2}(Q + 1)^2 \) element subset \((31)\) of \( G = \mathbb{F}_Q \times \mathbb{F}_{Q + 2} \), namely the complement of the classical twin prime power difference set. Then $D$ is a fine difference set, and is an amalgam if and only if $Q \equiv 3 \mod 4$. Moreover, $D$ is a composite difference set only when $Q = 3$.

Applying Theorem \( \text{[3.2]}(\text{d}) \) to these amalgams produces circulant conference matrices of size $S + 1 = Q + 2$. These conference matrices are distinct from those that arise from any known simplicial RDS via Theorem \( \text{[1.4]} \) since, as mentioned above, all of those are of size $Q + 1$ where $Q$ is a prime power. For example, when $Q = 11$, applying Theorem \( \text{[3.3]}(\text{d}) \) to \((31)\) gives, to our knowledge, the only known construction of a $13 \times 13$ circulant conference matrix; since 12 is not a prime power, the requisite RDS needed to apply Theorem \( \text{[1.4]} \) to produce such a matrix is not known to exist \( \text{[3]} \). These difference sets also provide our only known construction of amalgams that are not cyclic: when $Q = 27$, for example, \((31)\) is an amalgam for the group $\mathbb{F}_{27} \times \mathbb{F}_{29} \cong \mathbb{Z}_3 \times \mathbb{Z}_3 \times \mathbb{Z}_{87}$. We further note that in the case where $Q = 11$, the fact that $D$ is not composite means we should not expect the orthogonal projection operators onto the subspaces that constitute the corresponding ETFF to satisfy the property given in Theorem \( \text{[4.2]}(\text{b}) \); an explicit computation in this case reveals that they indeed do not have this property.

4.3.3. McFarland difference sets

For any prime power $Q$ and integer $J \geq 2$, regard $\mathbb{F}_Q^J$ as a $J$-dimensional vector space over the finite field $\mathbb{F}_Q$ of order $Q$. Let $K$ be any abelian group of order $Q^{J-1} + 1$, and let \( \{V_k\}_{k \in K, k \neq 0} \) be any enumeration of the distinct hyperplanes of $\mathbb{F}_Q^J$ according to the nonzero members of $H$. The set $D = \bigcup_{k \in K, k \neq 0} \{(k, v) : v \in V_k\}$ is then a McFarland difference set for the group $G = K \times \mathbb{F}_Q^J$. Here, a direct calculation reveals

\[ D = Q^{J-1}(Q^{-1} + 1), \quad G = Q^J(Q^{-1} + 1), \quad S := \frac{|D(G^{-1})|}{|D - G|} = \frac{Q^{J-1} + 1}{Q^J}, \quad H := \frac{G}{S + 1} = Q^J. \]

As noted in \( \text{[18]} \), every such $D$ is fine, being disjoint from a subgroup of order $H = Q^J$, namely $H = \{0\} \times \mathbb{F}_Q$. By Theorem \( \text{[3.3]} \), every coset of $H$ intersects $D$ in $\frac{D}{H} = Q^J - 1$ points; by inspection, these intersections are of the form $\{0\} \times V_k$ for some $k \in K$, $k \neq 0$. However,

\[ \frac{n^2}{S^2} = \frac{Q^{J-2}(Q - 1)}{Q^J(Q - 1)} = Q^{J-2}(Q - 1) + \frac{Q^{J-2}(Q - 1)}{Q^{J-2}} \]

is never an integer since $0 < Q^{J-2}(Q - 1) < Q^J - 1$. As such, any such difference sets are never amalgams, and so are never composite.

That said, even in this case, much of the machinery developed to prove Theorem \( \text{[3.3]} \) still provides insights into these fine difference sets that go beyond those provided by the techniques of \( \text{[18]} \). For instance, when $Q = 2$ and $J = 2$, $D = \{1000, 1001, 0100, 0110, 1100, 1111\}$ is a 6-element McFarland difference set for the group $G = \mathbb{Z}_2^4$ of order 16. Here, $D = 6$, $G = 16$, $S = 3$, and $D$ is disjoint from the subgroup $H = \{0000, 0010, 0001, 0111\}$ of order $H = \frac{G}{S + 1} = 4$. We identify $G$ with $\mathbb{Z}_2^4$, regarding $n_1 n_2 n_3 n_4$ as the character $g_1 g_2 g_3 g_4 \mapsto (-1)^{n_1 + n_2 + n_3 + n_4}$. In particular, $H^\perp$ is identified with those $n_1 n_2 n_3 n_4$ such that $(-1)^{n_3} = 1$, namely $\{0000, 1000, 0100, 1100\}$. Here, to form the corresponding $16 \times 16$ character table, we elect to order these characters lexicographically, that is, as $\{0000, 1000, 0100, 1100, 0010, \ldots, 1111\}$. Under these arbitrarily chosen orderings of $D$ and $G$, the synthesis operator of the corresponding harmonic ETF(6,16), formed by extracting the 6 rows of the character table that correspond to $D$ and then
normalizing columns, is:

\[
\Phi = \frac{1}{\sqrt{6}} \begin{bmatrix}
1 -1 & 1 -1 & 1 -1 & 1 -1 & 1 -1 & 1 -1 \\
1 -1 & 1 -1 & 1 -1 & 1 -1 & 1 -1 & 1 -1 \\
1 -1 -1 -1 & 1 -1 -1 -1 & 1 -1 -1 -1 & 1 -1 -1 -1 \\
1 -1 -1 -1 -1 -1 & 1 -1 -1 -1 -1 -1 & 1 -1 -1 -1 -1 -1 \\
1 -1 -1 -1 & 1 -1 -1 -1 & 1 -1 -1 -1 & 1 -1 -1 -1 & 1 -1 -1 -1 \\
1 -1 -1 -1 -1 & 1 -1 -1 -1 -1 & 1 -1 -1 -1 -1 & 1 -1 -1 -1 -1 & 1 -1 -1 -1 -1 \\
\end{bmatrix}.
\]

Here, for any \(n_1n_2n_3n_4\) in \(\mathcal{G}\), the corresponding 6 \(\times\) 4 submatrix \(\Theta\) is

\[
\Phi_{n_1n_2n_3n_4} = \left[ \varphi_{n_1n_2n_3n_4} \varphi_{(n_1+1)n_2n_3n_4} \varphi_{n_1(n_2+1)n_3n_4} \varphi_{(n_1+1)(n_2+1)n_3n_4} \right].
\]

As such, the above matrix \(\Phi\) can be regarded as the concatenation of \(\Phi_{0000}\), \(\Phi_{0010}\), \(\Phi_{0001}\) and \(\Phi_{0011}\). Meanwhile, the matrix \(\Psi\) in \(\Upsilon\) is obtained by removing the first row of the character table of \(\mathcal{G}/\mathcal{H} \cong \mathbb{Z}_2 \times \mathbb{Z}_2\), giving the synthesis operator of a particularly nice tetrahedron:

\[
\Psi = \frac{1}{\sqrt{3}} \begin{bmatrix}
1 -1 & 1 -1 \\
1 -1 & 1 -1 -1 \\
1 -1 -1 & 1 \\
\end{bmatrix}.
\]

Theorem 3.5(a) then gives \(\Phi_{n_1n_2n_3n_4} = E_{n_1n_2n_3n_4}\Psi\) where

\[
E_{0000} = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
\end{bmatrix}, \quad E_{0010} = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
\end{bmatrix}, \quad E_{0001} = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
\end{bmatrix}, \quad E_{0011} = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
\end{bmatrix}.
\]

As such, our ETF(6, 16) is comprised of four tetrahedra, each embedded in a 3-dimensional subspace \(\mathcal{U}_{n_3n_4} = \mathcal{U}_{n_1n_2n_3n_4} = C(E_{n_1n_2n_3n_4})\) of \(\mathbb{C}^D\). Moreover, Theorem 3.5(b) implies every corresponding cross-Gram matrix is diagonal. In fact, by inspection, the cross-Gram matrix of any pair of the above four isometries is one of the following three matrices:

\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
\end{bmatrix}, \quad \begin{bmatrix}
0 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
\end{bmatrix}, \quad \begin{bmatrix}
0 & 0 & 0 \\
0 & 0 & 1 \\
0 & 0 & 0 \\
\end{bmatrix}.
\]

From [18], we already knew that subspaces \(\{\mathcal{U}_{00}, \mathcal{U}_{10}, \mathcal{U}_{01}, \mathcal{U}_{11}\}\) are equi-chordal, implying all of these cross-Gram matrices have the same Frobenius norm. Here, we can say more: taking the absolute values of these diagonal entries of these cross-Gram matrices reveals that the principal angles between any pair of these subspaces are \(\{0, \frac{\pi}{2}, \frac{\pi}{2}\}\), meaning in particular that any pair of these subspaces intersect in a line. This is a hallmark feature of the subspaces spanned by the regular simplices that comprise a Steiner ETF. In fact, it is known that harmonic ETFs arising from McFarland difference sets are unitarily equivalent to certain Steiner ETFs arising from affine geometries [30]. What is remarkable is that, even if this fact was not already known, the machinery of Theorem 3.5 would have naturally led one to this realization.
5. Conclusions

We now have three, increasingly nice types of difference sets, namely fine difference sets, amalgams and composite difference sets, as given in Definitions 3.1, 3.6 and 4.1, respectively. Every composite difference set is an amalgam, and every amalgam is fine. In terms of the sets $D_g$ defined in (3), being fine equates to $D_g$ being empty when $g \in \mathcal{H}$, and having equal cardinality otherwise. When $D$ is an amalgam, we further have that each $D_g$ with $g \notin \mathcal{H}$ is a difference set for $\mathcal{H}$. When $D$ is a composite, we even further have that any two such $D_g$ are translates.

Properly shifted, the complements of “half” of all Singer difference sets are fine, and all of these are composite. Meanwhile, the complement of every twin prime power difference set is fine, and these are only amalgams when $Q \equiv 3 \mod 4$, and only composite when $Q = 3$. No McFarland difference set is an amalgam. Overall, we see that there are an infinite number of composite difference sets, as well as an infinite number of fine difference sets that are not amalgams. Moreover, there is a family of amalgams that are not composite, but whether or not this family is infinite depends on a form of the twin prime conjecture.

Every fine difference set $D$ yields an ECTFF in a natural way, and this ECTFF is moreover an EITFF if and only if $D$ is an amalgam. When $D$ is moreover composite, the corresponding orthogonal projection operators behave even more nicely than usual, satisfying (22). None of these EITFF’s disprove Conjecture 2.1.

Every composite difference set yields a simplicial RDS. Moreover, every amalgam and every simplicial RDS yields a circulant conference matrix. These constructions are two distinct generalizations of a common construction that applies to composite difference sets, with each generalization producing examples that the other does not: for any prime power $Q$, a simplicial RDS yields a circulant conference matrix of size $Q + 1$; when $Q$ and $Q + 2$ are twin prime powers with $Q \equiv 3 \mod 4$, the corresponding amalgam yields a circulant conference matrix of size $Q + 2$.
