Abstract
Prostate cancer is the second leading cancer in men world-wide. Due to its heterogeneous nature, a considerable amount of research effort has been dedicated in identifying effective clinical biomarkers with a focus on proteins, messenger RNA and microRNAs [1]. However, there is limited data on the role and expression of long noncoding RNAs (lncRNAs) in prostate cancer exosomes [2]. This array dataset which is linked to our publication describes the profiling of human lncRNAs in prostate cancer and their exosomes from five different cell lines [3]. From this dataset, we identified a list of statistically significant prostate cancer lncRNAs which are differentially expressed in the exosomes compared to their parent cell lines. This dataset has been deposited into Gene Expression Omnibus (GSE81034).

Keywords:
Exosome
lncRNA
Prostate cancer

2. Experimental design, materials and methods
The experiment design and data analysis pipeline is shown in Fig. 1. In the following sections, we review the experiment design, quality assessment of the prepared data and the analysis pipeline for this dataset.

3. Tissue culture of prostate cancer cell lines
Prostate cancer cell lines, LNCaP, PC3, and DU145 were cultured in RPMI medium, VCaP cells were grown in F12:DMEM and PNT2 cell lines in defined KSFM (Invitrogen, USA). All cells were incubated at 37 °C in 5% CO2, and supplemented with 1% v/v penicillin, streptomycin, glutamine and 10% v/v fetal calf serum. As Fetal Calf Serum contains exosomes of bovine origin all media were depleted of these bovine exosomes. To remove bovine exosomes, we utilized the ultracentrifugation protocol devised by Théry, C. et al. [2].

4. Isolation of exosomes using ultracentrifugation
Harvested culture was centrifuged twice, firstly at 500 g for 30 min, and then at 2000 g for 10 min to remove dead cells and any debris. The resulting supernatant was then centrifuged at 10,000 g for 30 min to separate micro-particles and other proteins from the exosomes. The supernatant was collected from this step and then centrifuged at 100,000 g for 120 min to obtain an exosomal pellet. The supernatant was discarded, and the pellet retained. The exosomal pellet was then resuspended in PBS and centrifuged at 100,000 g for 90 min. This resulting pellet contains the exosomes which was subjected to RNA isolation.

5. RNA extraction procedures

RNAzol RT (Molecular Research Center, USA) was used to extract total RNA from both cellular and exosomal sources [4]. 1 mL of RNAzol was added to the exosomal pellet and homogenised using a blunt needle syringe. This homogenate is added to 0.4 mL of water and left to incubate on ice for up to 15 min. The sample was then centrifuged at 4 °C, at 12,000 g for 15 min. 1 mL of the resulting supernatant was removed and purification performed via the addition of 5 μL of 4-bromoanisole. The sample was incubated for 3–4 min, and centrifuged at 12,000 g, 4 °C, for 10 min. The supernatant was removed from the sample, and 1 volume of isopropanol was added with 5 μL of glycogen (25 mg/mL) to precipitate the RNA. This mixture was then incubate on dry ice for 15 min followed by centrifugation at 12,000 g, 4 °C, for 10 min. The resulting RNA pellet was then washed twice in 75% ethanol and centrifuge at 8000g for 5 min to collect the pellet. After discarding the supernatant, the exosomal RNA pellet was solubilized with the addition of 50 μL of RNA/DNA free water.

6. Preparation of lncRNAs for hybridization to Agilent arrays

RNA Integrity and concentration was assessed post RNA extraction and prior to sample labeling. The sample RNA integrity number (RIN) was determined using a Bioanalyzer 2100 to assess RNA quality. RNA concentration, protein contamination and organic compound contamination was measured for all samples using the NanoDrop ND-1000. Agilent Low RNA Input Linear Amplification Kit PLUS was used for sample amplification and labeling. After washing, slides were scanned with the Agilent DNA Microarray Scanner. Data was extracted using Agilent feature extraction software. Normalization and further data analysis was performed using GeneSpring v11.5.1 software.
sample amplification and labeling. Hybridization was performed using the Agilent SureHyb Hybridization Chambers. The labeled cRNAs were hybridized onto the Human IncRNA array v2.0 (8 × 60 K, Arraystar) for the global profiling of 33,045 human IncRNAs. The IncRNAs in this array were collected from databases such as RefSeq, UCSC Known genes, and Ensembl. After washing the array slides, they were scanned using the Agilent Scanner G2505B. Agilent Feature Extraction software (version 10.7.3.1) was then used to analyze the acquired array images for 1) outlier analysis, 2) net signal statistics analysis, 3) local background statistical analysis, and 4) reproducibility analysis of the signals.

7. Data normalization and analysis

Quantile normalization was performed using the GeneSpring GX v11.5.1 software package (Agilent Technologies). After quantile normalization of the raw data, IncRNAs of which 6 out of 10 samples had flags in Present or Marginal (“All Targets Value”) were adjusted by Combat program to remove batch effects and were chosen for differentially expressed IncRNA screening. In the next step, quality assessment of IncRNA data for the different cell lines was performed by 1) investigating the box plot of the normalized intensity values to compare the distributions of intensities among different samples (Fig. 2A) and 2) inspecting the scatter plot of the log2 scaled values of the averaged normalized signal values of the exosomes versus the cells of each cell line to assess the IncRNA expression variations (Fig. 2B). To identify differentially expressed IncRNA, a fold change filtering with a threshold of fold change ≥2.0 was performed. Generation of the heatmaps and the hierarchical cluster analysis was performed using Agilent GeneSpring GX v11.5.1.

8. Discussion

Our dataset represents a novel categorization of IncRNA levels in prostate cancer exosome and their parental lineages. We have profiled four common prostate cancer cell lines and compared these to the normal PNT2 cells. Our array data suggested that IncRNAs are present in abundance in both healthy and prostate cancer exosomes. We normalized the data using quantile normalization and then filter the data by using a two-fold threshold. From this the dataset, we also identified 26 down-regulated and 19 upregulated IncRNAs which were common to these exosomes. Furthermore, these exosomal IncRNAs appeared to be enriched for miRNA seeds with a preference for miR-17, miR-18a, miR-20a, miR-93, miR-106b and the let-7 family members [3]. With these observation, we put forward the notion that IncRNAs can act as miRNA sponges and their specific enrichment in exosomes is an important step in prostate cancer carcinogenesis. The heat maps clearly showed the similarities and differences in the IncRNA expression between cancer exosomes/cells versus the normal exosomes/cells (Fig. 3). Although there have been many studies using small ncRNAs for cancer diagnosis [1], with this dataset, it may be possible to discover potential exosomal IncRNAs which can be utilized for prostate cancer diagnosis.
