Polymorphisms in the interleukin-4 receptor α chain (IL-4Rα) have been linked to asthma incidence and severity, but a causal relationship has remained uncertain. In particular, a glutamine to arginine substitution at position 576 (Q576R) of IL-4Rα has been associated with severe asthma, especially in African Americans. We show that mice carrying the Q576R polymorphism exhibited intense allergen-induced airway inflammation and remodeling. The Q576R polymorphism did not affect proximal signal transducer and activator of transcription (STAT) 6 activation, but synergized with STAT6 in a gene target– and tissue-specific manner to mediate heightened expression of a subset of IL-4– and IL-13–responsive genes involved in allergic inflammation. Our findings indicate that the Q576R polymorphism directly promotes asthma in carrier populations by selectively augmenting IL-4Rα–dependent signaling.

Asthma is an obstructive airway disease that affects an unusually large segment of the population and results in significant morbidity, and at times mortality. It is well appreciated that predisposition to asthma is genetically determined, whereas its clinical expression is controlled by environmental factors (Gern et al., 1999). Genes of the IL-4–IL-13–IL-4R cytokine pathway have been identified as leading candidates in asthma (Ober and Hoffjan, 2006). These functionally overlapping cytokines are key effectors of Th2-dependent responses, including stimulation of IgE synthesis, modulation of lymphocyte and antigen-presenting cell function, and induction of allergic inflammation. In the allergen–exposed airway, this inflammatory response involves recruitment of eosinophils, mucin hypersecretion, generation of airway hyperresponsiveness (AHR), and, eventually, airway remodeling, characterized by subepithelial fibrosis, neovascularization, and other permanent alterations in airway microanatomy (Elias et al., 1999).

IL-4 and IL-13 share a common receptor component, the IL-4Rα chain, that pairs with distinct subunits (Nelms et al., 1999; Hershey, 2003; Chatila, 2004). IL-4Rα pairs with the common γc chain to form a type I IL-4R complex that is found predominantly in hematopoietic cells and is exclusive for IL-4. IL-4Rα also pairs with the IL-13Rα1 subunit to form a type II IL–4R that binds both IL-4 and IL-13. The type II receptor is expressed on both hematopoietic and nonhematopoietic cells such as airway epithelium. IL-4 and IL-13 activate receptor-associated Janus kinases, which initiate several intracellular signaling cascades by phosphorylating specific tyrosine (Y) residues in the cytoplasmic domain of IL-4Rα (Nelms et al., 1999; Hershey, 2003; Chatila, 2004). Phosphorylation of Y575, Y603, and Y633 of human IL-4Rα mobilizes the transcription factor STAT6, which induces IL-4– and IL-13–responsive genes. Additional cell growth and regulatory functions are served by Y497, which
activates phosphatidylinositol 3 (PI3)–kinase and mitogen-activated protein kinase (MAPK) pathways, and by an immuno-
receptor tyrosine–based inhibitory motif (ITIM) at Y713 that activates phosphotyrosine and inositol phosphatases.

An essential role for IL-4Rα signaling in asthma pathoge-
genesis has been established (Chatila, 2004). Increased expres-
sion of IL-13 and, to a lesser extent, IL-4 in mouse airways reproduces many of the pathophysiological changes that are
typical of asthma (Elia et al., 1999). Blockade of IL-13 or dele-
tion of IL-4Rα or STAT6 genes renders mice resistant to
the induction of experimental allergic asthma (Grüning et al.,
1998; Wills-Karp et al., 1998). IL-4Rα chain expression in
resident airway tissues is required for development of allergic
airway inflammation upon antigen exposure. Induction of
AHR, goblet cell metaplasia, and mucin overproduction have
been found to be dependent on IL-4Rα signaling in airway
epithelial cells (Kuperman et al., 2002). Furthermore, coding
 genetic polymorphisms in the human IL-4Rα chain gene
have been implicated in susceptibility to both atopy and
asthma (Hershey et al., 1997; Ober et al., 2000; Howard et al.,
2002). Of particular interest is the Q576R polymorphism that
is associated with asthma susceptibility in outbred populations,
especially severe asthma (Hershey et al., 1997; Rosa-Rosa
et al., 1999; Ober et al., 2000; Sandford et al., 2000; Wenzel
et al., 2007). The Q576R polymorphism has also been linked
to severe respiratory syncytial virus–induced bronchiolitis
(Hoebee et al., 2003), rapid decline in lung function in smok-
ers (He et al., 2003), and heightened allergen sensitization in
the context of maternal smoking (Liu et al., 2004). Of inter-
est, this allele is overrepresented in the African-American
population (70% allele frequency in African Americans vs.
20% in Caucasians, giving rise to 50 and 4% homozygosity,
respectively; Caggana et al., 1999; Ober et al., 2000; Wu
et al., 2001; Akinbami and Schoendorf, 2002; Mannino et al.,
2002). In concert with increased frequency of the Q576R
polymorphism, African Americans suffer from heightened
asthma prevalence and severity. To address the role of the
Q576R polymorphism in allergic airway inflammation, we
have developed a mouse model in which the Q576 residue,
which is conserved in mice, is changed to R576.

RESULTS

Generation of IL-4RαR576 mutant mice by targeted
knock–in mutagenesis

To elucidate the impact of the human Q576R polymorphism
on IL-4Rα function, we adopted a genetic approach that took
advantage of the conservation of the Q576 motif (peptide se-
quence 574–GYQEFQG–579) in mouse and human to substi-
tute the equivalent glutamine residue of the mouse receptor
(also Q576) with arginine. A targeting construct was designed
to replace exon 12 of Il4ra of embryonic stem (ES) cells with
another bearing AG→GA substitutions at the second and
third positions of the Q576 codon that changed the codon
specificity to R576 (Fig. S1 A; Wrighton et al., 1992). Suc-
cessfully targeted ES clones were used to derive mouse male
chimera that transmitted the R576 mutation into the germine
(Fig. S1 B). Matings of IL-4Rα heterozygotes (Hets) resulted
in generation of R576 homozygous mutant mice in numbers
consistent with Mendelian inheritance. Homozygous mutant
mice of both sexes were phenotypically indistinguishable from
their WT and Het littermates. The transmission and integrity
of the mutant allele was verified by several methods, including
Southern blot analysis, allele-specific PCR amplification, and
direct sequencing of genomic DNA (Fig. S1, B–D; and not
depicted). Expression of mutant receptor protein was verified by
flow cytometry to be closely matched to WT controls (Fig. S1 E).
Analysis revealed the T and B lymphocytes of the
IL-4Rα R576 mutant mice to be normal in number and phe-
onotype (unpublished data).

The R576 allele promotes antigen–induced allergic
airway inflammation and remodeling

The functional consequences of the R576 mutation were
analyzed in antigen–driven mouse models of allergic airway
inflammation. In an acute model of allergic airway inflamma-
tion, C.129.II4raQ576/R576 and C.129.II4raQ576/Q576 mice were
t.p. sensitized and boosted with OVA in alum, and challenged
at 4 wk after sensitization with inhaled OVA for three con-
secutive days. Control mice were immunized and boosted
with PBS/alum and challenged with inhaled OVA. Examina-
tion of lung tissue of WT and mutant mice stained with
hematoxylin and eosin (H&E) revealed patchy peribronchial
inflammatory infiltrates, composed primarily of eosinophils
and lymphocytes, that were substantially more prominent
in OVA–sensitized and –challenged C.129.II4raQ576/R576 mice
as compared with C.129.II4raQ576/Q576 controls (Fig. 1 A).
In contrast, sham–immunized mice exposed to aerosolized
OVA showed normal lung histology (unpublished data).
Significantly, OVA–challenged C.129.II4raQ576/R576 mutants
exhibited markedly increased peribronchial and perivascular
inflammation and increased numbers of goblet cells com-
pared with C.129.II4raQ576/Q576 controls (Fig. 1, B and C;
Grünig et al., 1998; Wills-Karp et al., 1998; Dabbagh et al.,
1999; Kuperman et al., 2002). Analysis of bronchoalveolar
lavage (BAL) fluid of OVA–sensitized and –challenged mice
revealed that C.129.II4raQ576/R576 mice exhibited increased
accumulation of eosinophils in the airways as compared with
similarly treated controls (Fig. 1 D). These results indicated
that the R576 substitution caused an increase in the airway
inflammatory response to allergen.

We next examined the impact of the R576 mutation on
airway inflammation and remodeling in chronic OVA–driven
allergic airway inflammation (Wegmann et al., 2005). This
model better reflects some of the physiological changes
associated with chronic asthma, including subepithelial
fibrosis. Accordingly, C.129.II4raR576/R576 and control
C.129.II4raQ576/Q576 mice were sensitized and boosted with
OVA in alum, and starting at week 4 after sensitization they
were challenged with OVA by inhalation twice daily for an
additional 8 wk (Wegmann et al., 2005). Histological analy-
sis revealed that the C.129.II4raR576/R576 mice exhibited
increased perivascular inflammation and tissue eosinophilia.
as compared with control mice (Fig. 2, A–E, arrows in B and D). Sirius red staining revealed markedly increased subepithelial collagen deposition in the mutant mice as compared with controls (Fig. 2, F–J). These findings indicated that the R576 mutation exacerbated chronic sequelae of airway inflammation, such as airway remodeling, that are key determinants of disease morbidity in asthma.

The R576 allele promotes IL-13–induced allergic airway inflammation

Many aspects of antigen–induced allergic airway inflammation, including AHR, eosinophilic infiltration, goblet cell metaplasia, and tissue remodeling, can be induced by the direct action of IL-13 on resident airway tissue independent of the adaptive immune response. To determine whether
the R576 mutation could augment IL-13–induced airway inflammation, C.129.IIl4raR576/R576 and WT BALB/c control mice were subjected to daily instillations of recombinant IL-13 or vehicle alone (BSA) for three consecutive days and compared for the magnitude of their responses. For both genotypes, the IL-13–challenged mice developed an allergic inflammatory response characterized by AHR to methacholine, eosinophilic infiltration, and goblet cell hyperplasia. (Fig. 3, A–D). However, for each of these parameters the C.129.Il4raR576/Q576 mice exhibited an enhanced response as compared with WT BALB/c control mice, indicating that the R576 substitution augmented the IL-13–induced airway inflammation.

These results were validated in a second IL-13–dependent allergic airway inflammatory model that used a doxycycline-responsive IL-13 transgene (tg) driven by the Clara cell–specific promoter CC10 and maintained on a C57BL/6 background. Double-transgenic B6.IIl4raR576/Q576/IL-13tg mice were derived and compared with single-transgenic B6.Il4raQ576/Q576/IL-13tg mice for allergic airway inflammation both in the absence of and upon treatment with doxycycline for a total of 7 d. Both sets of mice exhibited basal airway eosinophilia and goblet cell metaplasia as compared with their respective IL-13tg-negative controls, a reflection of the leaky nature of the IL-13tg (Fig. 4 A; Zheng et al., 2000). Importantly however, the B6.Il4raR576/IL-13tg double-transgenic mice exhibited increased basal airway eosinophilia as compared with the B6.IIl4raQ576/Q576/IL-13tg single-transgenic mice, and this difference was further amplified upon doxycycline induction of IL-13 (Fig. 4 A). Although the single- and double-transgenic mice exhibited equivalent percentages of goblet cells at baseline, the B6.IIl4raR576/Q576/IL-13tg double-transgenic mice were more responsive to doxycycline treatment. While the percentage of goblet cells doubled upon doxycycline treatment of IL-13tg single-transgenic mice, it nearly quadrupled in the similarly treated B6.IIl4raR576/Q576/IL-13tg mice was associated with increased detection by real-time PCR analysis of mRNA encoding the eosinophil chemotactic factor Ccl11 (eotaxin; Fig. 4 C). In contrast, transcripts of other chemokines such as Ccl2 were not significantly affected (Fig. 4 D). The capacity of the R576 mutation to up-regulate IL-13–induced Ccl11 expression in the airways was mirrored in studies on primary cell cultures of several lineages involved in allergic airway inflammation. Both IL-4– and IL-13–induced Ccl11 expression was increased in bone marrow–derived macrophages (BMDMs) and lung fibroblasts derived from R576 mutant mice as compared with WT controls (Fig. 4 E). Collectively, these results established that the R576 substitution heightened IL-13–induced allergic airway inflammation and tissue eosinophilia irrespective of the genetic background of the mice tested.

Figure 3. The Q576R substitution promotes airway hyperreactivity, airway eosinophilia, and goblet cell metaplasia after IL-13 administration. (A) WT BALB/c mice [Q576; genotype Il4raQ576/Q576] and C.129.Il4raR576/Q576 (R576) mutant mice (n = 14–15 mice per group) were tested for their enhanced pause (Penh) response, a proxy measure of AHR, to aerosolized methacholine at 96 h after three daily intranasal instillations of IL-13 or BSA (5 µg each). Group responses were analyzed by repeated measures ANOVA (P < 0.001, R576/IL-13 vs. Q576/IL-13 groups). (B) Eosinophil count in BAL fluid. (C) PAS staining of IL-13–treated lung tissue. Arrowheads represent PAS+ goblet cells. (D) Enumeration of PAS-positive goblet cells. Values represent means ± SEM derived from three to four independent experiments. **, P < 0.01; *** P < 0.001. Bar, 100 µm.
Expression profiling revealed that the induction by doxycycline of IL-13tg expression resulted in the up-regulation of related sets of canonical IL-13–responsive genes in the B6.129Il4ra^{R576/Q576}/IL-13tg and B6.129Il4ra^{R576/R576}/IL-13tg mice as compared with their respective control groups (Tables S1 and S2). Comparison of the gene sets up-regulated by the IL-13tg revealed several asthma-related genes that met a rather restrictive criterion for selection (a twofold change cutoff in expression) on the R576 but not the Q576 background (Tables S3 and S4). A more direct comparison of the magnitude of gene expression in doxycycline-treated B6.129Il4ra^{R576/R576}/IL-13tg versus B6.129Il4ra^{Q576/Q576}/IL-13tg mice, done at a more inclusive 1.2-fold change cutoff, continued to reveal enhanced expression of several IL-13–responsive genes in the homozygous R576 allele group as compared with their Q576 counterparts (Fig. 5 and Table S5). These included genes involved in airway inflammation and remodeling such as Retnlb (resistin-like β) and Alox15 (15 lipoxygenase; Chu et al., 2002; Mishra et al., 2007), goblet cell metaplasia (Clca3 and Clca1) (Nakanishi et al., 2001), mucin and mucin granule components (Muc5b and Gp2), regulators...
of ion transport (Fxyd3 and Fxyd4) (Geering, 2006), protease and protease inhibitors (Adam8 and Timp4) (King et al., 2004), and epithelial barrier formation (Spr2a; Zimmermann et al., 2005; Segre, 2006). When normalized for gene expression in the respective control groups, several IL-13–responsive genes persisted in being overexpressed in doxycycline-treated B6.129Il4raR576/R576/IL-13tg as compared with similarly treated B6.129Il4raQ576/Q576/IL-13tg mice, including Adra2a, Alox15, Cle3, Fxyd4, Cgp2, Muc5b, and Spr2a (Fig. 5 B). The results of the gene array studies were further validated by real-time PCR analysis, which confirmed the up-regulation by the R576 substitution of several IL-13–induced genes, including Alox15, Retnlb, and Spr2a (Fig. 5 C). These results established that the R576 substitution differentially up-regulated the transcription of a subset of IL-13–responsive genes, especially ones involved in mucus secretion and airway inflammation and remodeling.

The R576 mutation promotes IL-4 production by Th2 cells and IgE responses

To determine whether the R576 substitution influenced Th cell differentiation as a contributing factor in its promotion of allergic airway inflammation, we compared cytokine production of T cells of C.129.II4raR576/R576 and control C.129.II4raQ576/Q576 mice that were induced to differentiate in vitro into Th1 or Th2 effector lymphocytes. C.129.II4raR576/R576 Th2 cells exhibited a significant increase in IL-4 production as compared with C.129.II4raQ576/Q576 Th2 cells. In contrast, production of the Th2 cytokines IL-5 and IL-13 was not significantly different between the two populations (Fig. 6 A). Similarly, there was no significant difference in IFN-γ production between Th1 cells of the respective genotype. These results indicated that the R576 substitution selectively up-regulated IL-4 production by Th2 cells.

The impact of the Q576R polymorphism on humoral immunity was examined by measuring the total and antigen-specific antibody responses after immunization with OVA mixed with alum adjuvant to promote Th2-type responses (Brewer et al., 1999), or with saline/alum as immunization control. Fig. 6 B revealed that the C.129.II4raR576/R576 mice exhibited increased total serum concentrations of IgE after immunization with OVA/alum as compared with C.129.II4raQ576/Q576 control mice. In contrast, IgG1 levels were unchanged (unpublished data). Significantly, OVA-specific antibody responses were also increased in the Q576R mutant mice as compared with controls (Fig. 6 B). The heightened IgE production in the Q576R mutant mice was associated with an increased capacity of the C.129.II4raR576/R576 B cells to produce IgE but not IgG1 when stimulated in vitro with anti-CD40 mAb plus IL-4 (Fig. 6 C). Also, the R576

Figure 5. The R576 substitution heightens the expression of a subset of IL-13–induced genes in the airways. (A) Differential expression of a subset of IL-13–induced genes in doxycycline-treated (Dox) B6.129Il4raR576/R576/IL-13tg double-transgenic versus B6.129Il4raQ576/Q576/IL-13tg single-transgenic mice (n = 11 and 8, respectively). Results depict mean fold change values scoring P < 0.05 by the Student’s unpaired two-tailed t test. (B) Selected results from A were normalized for gene expression levels in doxycycline-treated, IL-13tg–negative B6.129Il4raR576/R576, and B6.129Il4raQ576/Q576 littermate controls, respectively (n = 5 for each control group). (C) Real-time PCR analysis of Alox15, Retnlb, and Spr2a mRNA levels in total lung extracts of doxycycline-treated and IL-13tg–negative and positive Q576 and R576 mice (n = 4–11 per group). Values represent means ± SEM derived from two to four independent experiments, *, P < 0.05; and **, P < 0.01 for doxycycline-treated R576/IL-13tg versus Q576/IL-13tg groups.
substitution did not affect the up-regulation by IL-4 of CD23 and the MHC class II antigen expression in B cells, which proceeds in a STAT-6–dependent manner (Fig. 6 D; Kaplan et al., 1996; Shimoda et al., 1996).

We also examined the impact of the R576 substitution on the induction in BMDMs of the STAT6–dependent genes arginase 1 (Arg1) and chitinase (Chi3l3) and of arginase enzymatic activity (Gordon, 2003; Munitz et al., 2008; Ramalingam et al., 2008). Although the R576 substitution augmented Ccl11 gene expression in BMDMs (Fig. 4), it did not influence the induction of Arg1 and Chi3l3 transcripts nor the expression of arginase enzymatic activity in BMDM cells treated with IL-4 or IL-13 (Fig. S2). Collectively, these results established that the R576 substitution selectively augmented some IL-4R–dependent responses in T and B cells and in BMDMs but not others.

The R576 substitution does not augment proximal STAT6 activation

To elucidate signaling mechanisms by which the R576 substitution mediates its proallergic inflammatory effects, we examined the capacity of the R576 mutation to augment the activation of STAT6 in different cell types in response to IL-4 and IL-13. Results revealed that the R576 substitution did not augment the increase in STAT6 phosphorylation in response to IL-4 in T or B cells, nor did it alter the time course of STAT6 dephosphorylation in both cell types upon the cessation of IL-4 treatment (Fig. 7, A–C). Because T and B cells express the type I but not type II IL-4R and, as such, do not respond to IL-13, we examined STAT6 activation in response to IL-4 and IL-13 in BMDMs, which express both the type I and II IL-4Rs. There were no differences in the induction of STAT6 phosphorylation, or in its dephosphorylation upon signal termination, between WT and R576 mutant BMDMs treated with IL-4 or IL-13 (Fig. 7, D–F and G–I, respectively). These results established that the R576 substitution did not directly affect STAT6 activation in T and B lymphocytes or BMDMs.

We also examined the activation of several pathways downstream of IL-4R that have been previously implicated in receptor signaling. The R576 substitution was not associated with enhanced Shc phosphorylation, nor was it associated with enhanced activation of the PI3-kinase–Akt pathway, suggesting that the association at the I4R motif and the subsequent activation of the adaptor IRS2, which lies upstream of PI3-kinase–Akt, was similarly unperturbed (Fig. S3).

To further determine the role of STAT6 in the up-regulation of allergic airway inflammation in the R576 mutant mice, we examined the induction of goblet cell metaplasia and tissue eosinophilia in doxycycline-treated WT and mutant mice that harbor the CC10-driven IL-13tg and are either STAT6 sufficient or deficient. Goblet cells and eosinophils were detected by tissue staining with anti-MUC5AC and anti-eosinophil major basic protein 1 (MBP1) antibodies, respectively. Results revealed that although doxycycline-/IL-13tg–induced goblet cell metaplasia was increased in the R576 mutant mice as compared with the Q576 control mice, concurrent STAT6 deficiency abrogated goblet cell metaplasia in both mouse strains (Fig. 8, A and B). STAT6 deficiency reduced tissue eosinophilia induced by doxycycline/IL-13tg.
back to background levels in Q576 control mice. In contrast, the STAT6-deficient R576 mutant mice continued to exhibit significantly increased eosinophil infiltration, reaching up to 50% of that observed in STAT6-sufficient R576 mutant mice (Fig. 8, C and D). The residual, STAT6-independent tissue eosinophilia in the triple-transgenic B6.12Il4raR576/R576/STAT6−/−/IL-13tg mice involved a Ccl11- and Alox15-independent mechanism, as the increased Ccl11 and Alox15 expression induced by the IL-13tg was abolished in both WT and mutant mice by concurrent STAT6 deficiency (Fig. 8, E and F). Hence, although the R576 mutation augmented several STAT6-dependent responses, the promotion by R576 allele of tissue eosinophilia involved both STAT6-dependent and -independent mechanisms.

**Activation of alternative signaling pathways by the R576 substitution**

To determine potential alternative mechanisms by which the R576 substitution promoted allergic airway inflammation, we examined the activation of other pathways downstream of IL-4R that have been previously implicated in receptor signaling. Induction of IL-13tg expression by doxycycline treatment was associated with enhanced MAPK phosphorylation in lung extracts of B6.12Il4raR576/R576/IL-13tg mice as compared with similarly treated B6.12Il4raR576/R576/IL-13tg controls (Fig. S3 A). Similarly, treatment of primary cultures of tracheal airway epithelial cells (TECs) revealed that IL-4 treatment of C.129.129R576/R576 cells was associated with enhanced Erk1/2 kinase activation (Fig. S3 B). IL-4 (and IL-13) treatment of C.129.129R576/R576 TEC cultures was not associated with enhanced Shc phosphorylation, suggesting that the enhancement of MAPK activation proceeded by a distinct mechanism (Fig. S3 B and not depicted). Treatment of TEC cultures with IL-4 resulted in increased expression of Ccl11 transcripts, with a twofold superinduction noted in mutant C.129.129R576/R576 TECs as compared with C.129.129Q576/Q576 controls. This differential induction of Ccl11 transcripts in mutant TEC cells was sensitive to inhibition by the MAPK inhibitor PD98059 (Fig. S3 C). Activation of other downstream kinases, including AKT and p38 back to background levels in Q576 control mice. In contrast, the STAT6-deficient R576 mutant mice continued to exhibit significantly increased eosinophil infiltration, reaching up to 50% of that observed in STAT6-sufficient R576 mutant mice (Fig. 8, C and D). The residual, STAT6-independent tissue eosinophilia in the triple-transgenic B6.12Il4raR576/R576/STAT6−/−/IL-13tg mice involved a Ccl11- and Alox15-independent mechanism, as the increased Ccl11 and Alox15 expression induced by the IL-13tg was abolished in both WT and mutant mice by concurrent STAT6 deficiency (Fig. 8, E and F). Hence, although the R576 mutation augmented several STAT6-dependent responses, the promotion by R576 allele of tissue eosinophilia involved both STAT6-dependent and -independent mechanisms.

**Activation of alternative signaling pathways by the R576 substitution**

To determine potential alternative mechanisms by which the R576 substitution promoted allergic airway inflammation, we examined the activation of other pathways downstream of IL-4R that have been previously implicated in receptor signaling. Induction of IL-13tg expression by doxycycline treatment was associated with enhanced MAPK phosphorylation in lung extracts of B6.12Il4raR576/R576/IL-13tg mice as compared with similarly treated B6.12Il4raR576/R576/IL-13tg controls (Fig. S3 A). Similarly, treatment of primary cultures of tracheal airway epithelial cells (TECs) revealed that IL-4 treatment of C.129.129R576/R576 cells was associated with enhanced Erk1/2 kinase activation (Fig. S3 B). IL-4 (and IL-13) treatment of C.129.129R576/R576 TEC cultures was not associated with enhanced Shc phosphorylation, suggesting that the enhancement of MAPK activation proceeded by a distinct mechanism (Fig. S3 B and not depicted). Treatment of TEC cultures with IL-4 resulted in increased expression of Ccl11 transcripts, with a twofold superinduction noted in mutant C.129.129R576/R576 TECs as compared with C.129.129Q576/Q576 controls. This differential induction of Ccl11 transcripts in mutant TEC cells was sensitive to inhibition by the MAPK inhibitor PD98059 (Fig. S3 C). Activation of other downstream kinases, including AKT and p38...
MAPK, appeared unaffected by the R576 substitution (unpublished data). Collectively, these findings identified enhanced MAPK activation as one putative effector mechanism of the IL-4Rα R576 substitution.

DISCUSSION
Several factors restrict the interpretation of association studies examining the role of genetic polymorphisms in the pathogenesis of allergic diseases, including asthma. These include the genetic heterogeneity of outbred human populations, which results in confounding genetic influences from other disease susceptibility and modifier loci. In addition, the polymorphisms under study might be but markers in linkage disequilibrium with other true disease susceptibility loci. Finally, any particular polymorphism may influence only selective aspects of a complex phenotype such as asthma. In the present study, we have addressed some of these restrictions as they apply to the IL-4Rα Q576R polymorphism by studying the functional impact of this polymorphism in the context of the mouse receptor, in which the Q576 residue and the motif within which it is embedded are conserved. By comparing the functional attributes of the WT and the R576 mutant

---

**Figure 8.** STAT6-dependent and -independent effects of the R576 substitution. (A and B) Induction of MUC5AC expression in airway epithelial cells. (A) IL-13tg+ B6.Ilr4αQ576/Q576 and B6.129Ilr4αR576/R576 mice, and tg-negative controls, that were either STAT6 sufficient or deficient were examined by immunofluorescence staining for expression of MUC5AC after doxycycline (Dox) treatment (red-staining cells). (B) MUC5AC+ cells (red-staining cells; A) were counted and expressed as the percentage of total airway epithelial cells (DAPI [blue]-staining nuclei) in the respective airways. (C and D) Lung tissue eosinophilia. (C) Mouse groups as in A were treated with doxycycline, and their lungs were stained with anti-eosinophil MBP1 antibodies (red-staining cells). (D) MBP1+ cells were counted and expressed as mean cell numbers per 20× objective field (n = 10 fields per group). (E and F) Real-time PCR analysis of Ccl11 and Alox15 expression in the different mouse groups treated with doxycycline. Values represent means ± SEM of 4–15 mice per group derived from three to five independent experiments. *, P < 0.05; **, P < 0.01; ***, P < 0.001. Bars, 100 µm.
alleles on a homogenous genetic background, we have identified a role for this polymorphism in promoting atopic responses and allergic airway inflammation and remodeling.

The R576 allele potentiated allergic airway inflammation in an antigen-dependent (OVA sensitization) and -independent manner (IL-13 inhalation and transgenic expression). In both cases, the inflammation was associated with increased airway eosinophilia, which persisted in the chronic antigen-driven airway inflammation model. Given that airway eosinophilia plays a critical role in unfolding the acute and chronic changes associated with asthma, including AHR, mucous production, and subepithelial fibrosis, the increased airway eosinophil load would provide one mechanism by which the R576 allele promotes allergic airway inflammation (Humbles et al., 2004; Lee et al., 2004). Gene expression profiling identified additional mechanisms by which the R576 allele may exert proinflammatory functions. A subset of IL-13-regulated genes associated with airway inflammation, remodeling, and mucous production, including Alox15, Retnllb, Clca3, and others were superinduced by the R576 allele. Although some metabolites of 15-lipoxygenase, such as the lipoxins, may serve an antiinflammatory function, others such as 15(S)-hydroxyeicosatetraenoic acid may promote airway remodeling (Chu et al., 2002; Kühn and O'Donnell, 2006). In addition, expression of Clca3 is sufficient for induction of goblet cell metaplasia in mice (Patel et al., 2006). Collectively with the recent demonstration of the induction of subepithelial fibrosis by resistin-like β, these findings point to potential targets of intervention to interrupt the evolution of chronic airway changes promoted by the R576 allele (Mishra et al., 2007).

The R576 allele enhanced total and antigen-specific IgE responses, a likely reflection of both increased IL-4 production by Th2 cells and IL-4–driven isotype switching to e heavy chain in B cells. An increased atopic response and a heightened resident airway tissue response to IL-4 and IL-13 may both contribute to the aggressive allergic airway inflammatory phenotype of the R576 allele. However, the capacity of the R576 allele to potentiate IL-13–induced allergic airway inflammation, which proceeds in the absence of an IgE–associated adaptive immune response, indicates that the airway inflammatory phenotype can be uncoupled from the atopic response. Nevertheless, it is likely that the two mechanisms interact synergistically in vivo in the context of an antigen-driven allergic airway inflammation.

The proallergic inflammatory phenotype of the R576 allele was associated with the selective enhancement of some STAT6–dependent responses in a tissue- and gene-specific manner but in the absence of increased STAT6 phosphorylation on the regulatory tyrosine residue or the activation of pathways such as PI3-kinase–Akt, She, or p38 MAPK. These findings are in agreement with an earlier report that failed to document evidence of enhanced STAT6 activation in mouse cell lines transfected with a human IL-4R allele carrying the R576 substitution (Wang et al., 1999).

The capacity of the R576 substitution to selectively augment some STAT6–dependent responses in the absence of increased proximal STAT6 activation may be best explained by the activation by the R576 substitution of an alternative signaling mechanism that acts in synergy with STAT6 in a gene- and tissue-specific manner. This conclusion is supported by the finding that the enhanced eosinophil accumulation in lung tissues of Il4ra<sup>R576/R576</sup>/IL-13tg<sup>+</sup> mice proceeds in part by STAT6-independent mechanisms (Fig. 8). Increased MAPK activation was observed in lung tissues of Il4ra<sup>R576/R576</sup>/IL-13tg<sup>+</sup> mice and in cultured Il4ra<sup>R576/R576</sup> primary TECs, indicating that this may represent one such mechanism (Duan et al., 2005; Lee et al., 2006). However, the precise mechanisms by which the R576 alter signaling via the IL-4R, and the role of MAPK and other signaling pathways in mediating the effects of the R576 substitution, remains to be fully established.

Earlier studies have linked the R576 substitution to altered binding at Y575 with increased association with SHP-1 and SHP-2 (Hershey et al., 1997; Kruse et al., 2002). More detailed analysis revealed that recombinant SHP-1 protein selectively binds to the ITIM at positions Y713 and Y709 in the human and mouse receptors, respectively. Mutagenesis of the ITIM in vivo was associated with enhanced STAT6 phosphorylation, grossly elevated baseline serum IgE levels, and exaggerated total and antigen–specific IgE responses upon antigen sensitization (unpublished data). These findings indicate that the effects of the R576 substitution are distinct from those associated with disruption of a bona fide ITIM.

Epidemiological surveys have linked different IL-4Rα polymorphisms to distinct phenotypes of atopy and asthma. In particular, the R576 allele has been linked to severe asthma and low lung function in asthmatics. Other alleles such as the cysteine 431 arginine (C431R) have been linked to atopy, whereas the E400A has been linked to both severe asthma and atopy (Ober et al., 2000; Wenzel et al., 2007). Furthermore, the linkage to both asthma and atopy appears to be strengthened when analysis involves combinatorial haplotypes of different IL-4Rα polymorphisms, indicative of interaction among the alleles (Ober et al., 2000; Risma et al., 2002; Hytönen et al., 2004). These findings are consistent with some of the IL-4Rα polymorphisms acting by distinct though possibly overlapping mechanisms to promote atopy and asthma. It would be important to decipher the molecular mechanisms underlying these interactions, as they are likely to reflect on the different clinical phenotypes associated with asthma, including disease progression and severity.

Previous analysis has indicated that the association of the R576 polymorphism with severe asthma is independent of the racial group analyzed (Wenzel et al., 2007). However, the R576 polymorphism exists at a much higher prevalence among the racial group analyzed (Wenzel et al., 2007). However, the precise mechanisms by which the R576 alter signaling via the IL-4R, and the role of MAPK and other signaling pathways in mediating the effects of the R576 substitution, remains to be fully established.

Epidemiological surveys have linked different IL-4Rα polymorphisms to distinct phenotypes of atopy and asthma. In particular, the R576 allele has been linked to severe asthma and low lung function in asthmatics. Other alleles such as the cysteine 431 arginine (C431R) have been linked to atopy, whereas the E400A has been linked to both severe asthma and atopy (Ober et al., 2000; Wenzel et al., 2007). These findings are consistent with some of the IL-4Rα polymorphisms acting by distinct though possibly overlapping mechanisms to promote atopy and asthma. It would be important to decipher the molecular mechanisms underlying these interactions, as they are likely to reflect on the different clinical phenotypes associated with asthma, including disease progression and severity.
interactions between IL-13 and IL-4Rα alleles have been demonstrated for African Americans with asthma (Battle et al., 2007). The specific contribution of the R576 allele to asthma incidence and severity among different ethnic groups, especially African Americans, requires further investigation. Its association with a distinct mechanism of cellular activation via the IL-4Rα suggests, however, that novel therapeutic interventions may be beneficial to asthma treatment in this and other ethnic groups.

MATERIALS AND METHODS

Construction of targeting vector and generation of mutant mice. Genomic DNA used to construct the targeting vector was isolated from a bacterial artificial chromosome clone derived from the 129X1/SvJ mouse strain that contained the mouse IL-4Rα gene (Genome Systems; Wrighton et al., 1997). The replacement-type targeting vector (pKO; Lexicon) contained 13.5 kb of IL4Rα sequences that extended from a XhoI site proximal to exon 9 to a KpnI site distal to exon 12 of the gene. An AG→GA substitution was introduced by site-directed mutagenesis (QuickChange; Agilent Technologies) into the second and third positions of codon Q576 (corresponding to bp 1964–1965 of the mouse IL-4Rα cDNA; Mosley et al., 1989), changing it to R576 (CGA). The targeting construct included a floxed neomycin resistance gene (neo) and a diphtheria toxin gene for positive/negative selection. Targeting plasmids were transfected into RW4 ES cells and subjected to G418 selection. Successfully targeted clones were transiently transfected with a Cre recombinase to remove the inserted neomycin gene.

Heterozygous ES cells were injected into C57BL/6 blastocysts, and the resultant male chimeras were mated with BALB/c females. Offspring were screened for Hets by Southern blotting and PCR analysis. May-Grünwald–Giemsa stained bone marrow cells were prepared from chimeric mice by isolating femur and tibia. Heterozygous ES cells were injected into C57BL/6 blastocysts, and the resultant male chimeras were mated with BALB/c females. Offspring were screened for Hets by Southern blotting and PCR analysis. B6.129.If4ra<sup>+/−</sup> KO mice were obtained from The Jackson Laboratory.

Flow cytometry and intracellular staining. Single-color suspensions were stained with the antibodies indicated in the figures and analyzed on a flow cytometer (FACSCalibur; BD). FITC- or PE-conjugated mAbs used were obtained from BD and eBioscience. Intracellular staining with anti–phospho-Y641→STAT6 (pSTAT6), anti–phospho–threonine 308–AKT (pAKT), and anti–pT180/pY182 p38 MAPK (pp38) antibodies (BD) was performed as previously described (Krutzik et al., 2004). The following antibodies were used: anti–pSTAT6, -pAKT, -pERK1/2, and -p38 (Cell Signaling Technology). The blots were developed using horseradish peroxidase–conjugated secondary antibodies and enzyme-linked chemiluminescence (ECL; GE Healthcare).

Immunofluorescence. Tissue section preparation was performed as previously described (Gomperts et al., 2007). Sections were stained with either Alexa Fluor 647 (anti–mouse monoclonal antibodies or biotinylated secondary antibody and enzyme-linked chemiluminescence (ECL; GE Healthcare).

ARTICLE

serum total and OVA-specific IgE antibodies, in vitro IgE production, and Th cell differentiation. These assays were performed as previously described (Blaser et al., 2003).

Cell preparation, stimulation, and immunoblotting. Purified T and B cell populations were derived by magnetic bead separation (Blaser et al., 2000). BMDMs, primary lung fibroblast cultures, and primary air–liquid interface cultures of mTECs were established as previously described (Blaeser et al., 2000). The replacement-type targeting vector (pKO; Lexicon) was used to generate the control C.129H4<sup>+/−/−</sup> congenic mouse strain. WT BALB/c and IL-4Rα KO mice (BALB/c-Il4ra<sup>tm1/vs6</sup>) were obtained from The Jackson Laboratory.

Control and IL-13tg strains. The mouse Il4ra exists as two distinct allotypes, each restricted to different strains of inbred mice, that differ at a single amino acid (129X1/SvJ and C57BL/6 strains). The C.129H4<sup>+/−/−</sup> congenic mouse strain has been deposited at the Jackson Laboratory (strain no. 007746).

PCR analysis. Screening of WT and mutant Il4ra alleles was performed by PCR amplification using genomic DNA and the following primers: common forward (F) primer, 5′-TTGCAGACAATCTCTGGCTTA-3′; WT-specific reverse (R) primer, 5′-ACTGCTGTGACAAATCCTC-3′; and mutant-specific R primer, 5′-ACTGCTGTGACAAATCCTC-3′. The following primers were used for PCR screening of the residualLoxP-containing allele: F, 5′-GGTGCTCTATTTAGGTTGCC-3′, and R, 5′-CTCTCTCTCTCTCTCTCCTGCT-3′. For RT-PCR analysis, total RNA was extracted from spleenocytes of WT and IL-4Rα R576R mutant mice using TRIzol (Invitrogen). The RNA was treated with DNase I to remove residual genomic DNA contamination and reverse transcribed. Il4ra transcripts were amplified by a two-step process using the following pairs of nested primers: outer pair F (exon 11), 5′-CAGACCCGAAGCAGGATCACC-3′, and R, (exon 12) 5′-CCCTGCTTCCCTGCTGCAACAAAC-3′; and inner pair (both exon 12) F, 5′-GAGGACCTCCACACACGACGACAGCGACAC-3′, and R, 5′-ACTGCTGTGACAAATCCTC-3′. For GAPDH, the following primers were used: F, 5′-ACACAGCTCCATGCACTCAC-3′, and R, 5′-TCCACACCTCTGTCGTA-3′. For real-time PCR analysis, cDNA was reverse transcribed from 2 μg RNA per sample and used in real-time PCR assays that used commercially available oligonucleotides and SYBR green–based reagents (SA Bioscience). The comparative Ct (threshold cycle) method normalized to GAPDH was used to analyze relative changes in gene expression. The fold change was calculated as 2<sup>−ΔΔCt</sup> for negative ΔΔCt values (indicating a fold-change increase) and −2ΔΔCt for positive ΔΔCt values (indicating a fold-change decrease).

Flow cytometry and intracellular staining. Single-color suspensions were stained with the antibodies indicated in the figures and analyzed on a flow cytometer (FACSCalibur; BD). FITC- or PE-conjugated mAbs used were obtained from BD and ebioscience. Intracellular staining with anti–phospho-Y641→STAT6 (pSTAT6), anti–phospho–threonine 308→AKT (pAKT), and anti–pT180/pY182 p38 MAPK (pp38) antibodies (BD) was performed as previously described (Krutzik et al., 2004). Cell aliquots were stimulated with IL-4 or IL-13 at the concentrations and time periods indicated in the figures. Immunoblotting was performed as previously described (Blaser et al., 2000). The following antibodies were used: anti–pSTAT6, -pAKT, -pERK1/2, and -p38 (Cell Signaling Technology). The blots were developed using horseradish peroxidase-conjugated secondary antibodies and enzyme-linked chemiluminescence (ECL; GE Healthcare).

Immunofluorescence. Tissue section preparation was performed as previously described (Gomperts et al., 2007). Primary antibodies used were mouse anti–Muc5AC mAb (1:100; Neomarkers) and 0.4 μg/ml of monoclonal rat anti–mouse eosinophil MBP1 mAb 14.7.4 (a gift of J. Lee; Mayo Clinic Arizona, Scottsdale, AZ). Sections were incubated with either Alexa Fluor 647 goat anti–mouse antibody (for MUC5AC staining) or biotinylated secondary antibody and enzyme-linked chemiluminescence (ECL; GE Healthcare).

serum total and OVA-specific IgE antibodies, in vitro IgE production, and Th cell differentiation. These assays were performed as previously described (Blaser et al., 2003).

Cell preparation, stimulation, and immunoblotting. Purified T and B cell populations were derived by magnetic bead separation (Blaser et al., 2000). BMDMs, primary lung fibroblast cultures, and primary air–liquid interface cultures of mTECs were established as previously described (You et al., 2002; Sugiuara et al., 2007). Cells were serum starved for 4 h (T and B cells) or overnight (BMDMs, fibroblasts, and mTECs) at 37°C before stimulation with IL-4 or IL-13 at the concentrations and time periods indicated in the figures. Immunoblotting was performed as previously described (Blaser et al., 2000). The following antibodies were used: anti–pSTAT6, -pAKT, and anti–p38 (Santa Cruz Biotechnology, Inc.). Immunoblotting was performed as previously described (Krutzik et al., 2004). Cell aliquots were stimulated with IL-4 or IL-13 (PeproTech) for the periods and concentrations indicated in the figures. The cells were then fixed with 1% paraformaldehyde and permeabilized for 10 min with methanol. After washing, the cells were stained with conjugated pSTAT6, pAKT, or pp38 (Alexa Fluor 647; BD) and analyzed by flow cytometry.

Immunofluorescence. Tissue section preparation was performed as previously described (Gomperts et al., 2007). Primary antibodies used were mouse anti–Muc5AC mAb (1:100; Neomarkers) and 0.4 μg/ml of monoclonal rat anti–mouse eosinophil MBP1 mAb 14.7.4 (a gift of J. Lee; Mayo Clinic Arizona, Scottsdale, AZ). Sections were incubated with either Alexa Fluor 647 goat anti–mouse antibody (for MUC5AC staining) or biotinylated secondary antibody for 45 min, and then with Texas red–avidin (for MBP1 staining). After washing in PBS, all slices were stained with DAPI (Vector Laboratories) for 2 min and mounted. All images were obtained with a fluorescent microscope (Axioskop 2 Plus; Carl Zeiss, Inc.) and a camera (AxioCam HR; Carl Zeiss, Inc.), and imaged with a scanner (AxioVision; Carl Zeiss, Inc.) and LE Real 4.2 software.
Macrophase and lung fibroblast cultures and arginase assay. BMDMs were derived by culturing bone marrow aspirates for 7 d with M-CSF, cultured in 24-well tissue culture plates, and stimulated with IL-4 or IL-13 at the concentrations and times indicated in the figures. The arginase assay was performed as previously described (Ramalingam et al., 2008). Primary lung fibroblast cultures were prepared as previously described (Sugurra et al., 2007).

Allergic airway inflammation models. For the acute antigen-induced airway inflammation model, mice were sensitized and boosted with a mixture of OVA in alum, and challenged 4 wk later intranasally with 50 µg OVA daily for three consecutive days. Control mice were sensitized and boosted with PBS mixed with alum, and challenged with OVA. For the chronic model, mice were immunized and boosted with OVA/alum, and starting on week 4, challenged twice weekly with intranasal OVA through week 12. Control mice were immunized with PBS/alum challenged with PBS. Inhaled IL-13–induced allergic airway inflammation was accomplished by instilling 5 µg of recombinant IL-13 intranasally daily for three consecutive days. Control instillation was performed using 5 µg BSA in 50 µl PBS. The IL-13tg–induced airway inflammation model was effected by feeding IL-13tg mice and their tg-negative littermates with doxycycline-containing chow (300 ppm; Research Diets, Inc.) for 1 wk.

Measurement of airway tissue and functional responses. Paraaffin-embedded lungs sections were stained with H&E and periodic acid–Schiff (PAS) staining as previously described (Wegmann et al., 2005). BAL was performed as previously described (Blaser et al., 2003). Airway functional responses were examined in mice treated intranasally with either recombinant IL-13 or BSA (5 µg/50 µl PBS for three consecutive days), and were measured at 24 h after the last inhalation treatment using whole-body plethysmography (Buxco). Peribronchiolar and subepithelial collagen deposition was detected by Sirius red staining (Wegmann et al., 2005). BAL fluid was analyzed for total RNA, which was then amplified and used to create probes for Affymetrix 430 2.0 chips. For the analysis of gene expression measures, all Affymetrix probes matching a target sequence were summarized using the first thresold (chosen to be the 10th percentile of all selected for further analysis). Listed genes had to additionally show a group mean difference above a threshold, chosen to be the 10th percentile of all measured for the group (Gentleman et al., 2004). Pairwise comparisons were made for all experimental conditions such that probe sets that showed at least a 1.2–2-fold change in expression, as specified for the respective group comparisons, were selected for further analysis. Listed genes had to additionally show a group mean difference above a threshold, chosen to be the 10th percentile of all group mean differences across all probe sets. Results represent mean fold change values derived from 5–11 independent arrays (one mouse per array) for the respective genotype, and scoring P < 0.05 by the Student’s unpaired two-tailed t test. Microarray data have been deposited in the Gene Expression Omnibus under accession no. 18010.

Statistical analysis. The Student’s t test, two-way analysis of variance (ANOVA), and repeat measures two-way ANOVA with the Bonferroni posttest analysis of groups were used to compare test groups, as appropriate. P < 0.05 was considered statistically significant.

Online supplemental material. Fig. S1 details the derivation of Il4raR576/R576 mutant mice. Fig. S2 shows the induction of arginase activity, and Arg1 and Chi333 transcripts in IL-4– and IL-13–treated Il4raQ737/W376 and Il4raR576/R576 BMDMs. Fig. S3 demonstrates the induction of MAPK activation in Il4raQ737/Q737 Il4raR576/R576 mice and TECs in response to IL-13 and IL-4. Gene expression profiles in the lungs of nontransgenic and IL-13tg Il4raQ737/Q737 Il4raR576/R576 mice are detailed in Tables S1–S5. Online supplemental material is available at http://www.jem.org/cgi/content/full/jem.20091480/DC1.

We thank N. Truong and B. Caplan for technical assistance, and J.J. Booth for animal care. We also thank Dr. J. Elias for his gift of IL-13tg mice, Dr. J. Lee for his gift of rat anti–mouse MBP1 mAbs, and Drs. R. Geha and B. Comports for critical reading of the manuscript.
