Nearly optimal first-order methods for convex optimization under gradient norm measure: An adaptive regularization approach

Masaru Ito∗        Mituhiro Fukuda†

December 2019

Abstract

In the development of first-order methods for smooth (resp., composite) convex optimization problems minimizing $L$-smooth functions, the gradient (resp., gradient mapping) norm is a fundamental optimality measure for which the best known iteration complexity to obtain an $\varepsilon$-solution is $O(\sqrt{LD/\varepsilon \log(1/\varepsilon)})$ for the distance $D$ from the initial point to the optimal solution set. In this paper, we report an adaptive regularization approach attaining this iteration complexity without the prior knowledge of $D$ which was required to be known in the existing regularization approach. To obtain further faster convergence adaptively, we secondly apply this approach to construct a first-order method that is adaptive to the Hölderian error bound condition (or equivalently, the Łojasiewicz gradient property) which covers moderately wide class of applications. The proposed method attains the nearly optimal iteration complexity with respect to the gradient mapping norm.

Keywords: smooth/composite convex optimization; accelerated proximal gradient methods; Hölderian error bound; adaptive methods

Mathematical Subject Classification (2010): 90C25; 68Q25; 49M37

1 Introduction

The class of proximal gradient methods is a fundamental tool for solving the composite convex optimization problem
\[ \varphi^* = \min_x [\varphi(x) \equiv f(x) + \Psi(x)], \]
where $f$ is an $L$-smooth convex function defined on a Euclidean space, i.e., $f$ is a continuously differentiable convex function with $L$-Lipschitz continuous gradient, and $\Psi$ is a proper, lower-semicontinuous convex function. Accelerated first-order methods for this class of problems have been well-studied as they provide optimal iteration complexity to obtain an $\varepsilon$-approximate solution under the measure $\varphi(\cdot) - \varphi^*$ for various classes of problems [2, 14, 17, 18, 20, 22].

A major interest in this paper is to consider the iteration complexity to obtain an $\varepsilon$-approximate solution with respect to the gradient mapping norm. The gradient mapping $g_L(x)$ is defined by
\[ g_L(x) = L(x - \text{prox}_{\varphi/L}(x - L^{-1}\nabla f(x))), \quad \text{where} \quad \text{prox}_{\varphi/L}(y) = \arg\min_x \left[ \Psi(x) + \frac{L}{2} \|x - y\|^2 \right], \]
and $g_L(x) = 0$ holds if and only if $x$ is optimal to (1). The norm $\|g_L(x)\|$ of the gradient mapping is a useful optimality measure as it is computable at each iteration (if prox$\varphi$ is computable) in contrast to the measure $\varphi(\cdot) - \varphi^*$ that is not verifiable if we do not know $\varphi^*$. Note that, for the smooth problems (i.e., the case $\Psi \equiv 0$), the gradient mapping $g_L(x)$ coincides with the gradient $\nabla f(x)$.

To find an approximate solution $x$ such that $\|g_L(x)\| \leq \varepsilon$, the best known iteration complexity of first-order methods for the problem (1) is

$$O\left(\sqrt{\frac{LD}{\varepsilon}} \log \frac{LD}{\varepsilon}\right),$$

where $D := \text{dist}(x_0, X^*)$ for an initial point $x_0$ and the optimal solution set $X^*$. This complexity is attained by a regularization technique [16] but it requires $D$ to be known in advance. Without the prior knowledge of $D$, accelerated gradient methods achieving the iteration complexity $O((LD/\varepsilon)^{2/3})$ seems to be the best known ones [6, 16, 23]. One aim of this paper is to report an adaptive algorithm (Algorithm 3) for the regularization technique that attains the iteration complexity (2) without the requirement of $D$, as shown in Corollary 4.3.

Another motivation is the development of an adaptive first-order method under the Hölderian Error Bound (HEB) condition, that is, given an initial point $x_0$, we assume that

$$\varphi(x) - \varphi^* \geq \kappa \text{dist}(x, X^*)^\rho, \quad \forall x \text{ such that } \varphi(x) \leq \varphi(x_0),$$

for some $\kappa > 0$ and $\rho \geq 1$. This condition is also related to the concept called the Lojasiewicz gradient inequality [10, 11] which is a useful tool for the development and the analysis of algorithms as well as first-order methods [1, 4]. These concepts are known to be satisfied under moderately mild assumptions such as when $\varphi$ is coercive and subanalytic (in particular, semi-algebraic) [3]. The coefficient $\kappa$ and the exponent $\rho$ are critical parameters to determine the convergence rate but they are difficult to estimate in general, so that the development of adaptive algorithms is an important issue.

For the problem (1) under the Hölderian error bound condition, we propose Algorithm 4, a restart scheme of the previous mentioned adaptive regularization algorithm. Our method is inspired by Liu-Yang’s method [8] as we employ an (approximated) proximal-point approach, where the main difference is the adaption parameter: Liu-Yang’s method adaptively estimate the coefficient $\kappa$ while our method adaptively determine the regularization parameter. As a result, without knowing the coefficient $\kappa$ and the exponent $\rho$, the proposed method adapts both the parameters $\kappa$ and $\rho$. To find an approximate solution $x$ such that $\|g_L(x)\| \leq \varepsilon$, we prove the following iteration complexity result (Corollary 4.5):

- Case $\rho = 1$. The algorithm finds an optimal solution with a finite iteration complexity, i.e., the iteration complexity is independent of $\varepsilon$ (if $\varepsilon$ is sufficiently small).

- Case $\rho \in (1, 2)$. The iteration complexity is $O(\log \log \varepsilon^{-1})$ (superlinear convergence).

- Case $\rho = 2$. The iteration complexity is $O(\log \varepsilon^{-1})$ (linear convergence).

- Case $\rho > 2$. The iteration complexity is $O(\varepsilon^{\rho-2} \log \varepsilon^{-1})$ (sublinear convergence).

The finite and the superlinear convergences in $\rho = 1$ and $\rho \in (1, 2)$, respectively, are due to accurate convergence analysis, which were not shown in the existing adaptive methods [8, 20]. Moreover, for the smooth problems (i.e., the case $\Psi \equiv 0$), we show that the proposed method attains the nearly optimal iteration complexity with respect to the gradient norm. We can also immediately deduce the nearly optimal iteration complexity result with respect to the measure $\varphi(\cdot) - \varphi^*$.
Table 1 shows the relation to existing adaptive first-order methods. All the algorithms in this table attain the nearly optimal iteration complexity with respect to the employed measure. The recent first-order methods [20, 22] are applicable to our problem (for specific $\Psi$) and they adapt both $\kappa$ and $\rho$ ensuring the nearly optimal iteration complexity with respect to the measure $\varphi(\cdot) - \varphi^*$. One advantage of our method compared with these methods is the (nearly optimal) convergence guarantee; the method of Roulet and d’Aspremont (see [22, Proposition 3.4]) is a fixed step algorithm (remark that, if we know $\varphi^*$, [22, Algorithm 3] gives nearly optimal convergence), and Reneger-Grimmer’s method [20] fixes the target tolerance $\varepsilon$. Although the other algorithms, i.e., this work and the first four algorithms [5, 7, 8, 17] in Table 1, terminate if an $\varepsilon$-solution is found, they provide the nearly optimal convergence letting $\varepsilon = 0$ as we discuss later.

Table 1: Adaptive first-order methods. The column ‘Parameters’ indicates the parameters that the algorithm can adapt. The column ‘Optimality measures’ is the optimality measure for which the nearly optimal iteration complexity was proved. The column ‘Convergence’ shows whether the algorithm ensures the convergence of the optimality measure to zero (at the nearly optimal rate).

| Algorithm | Problem class | Parameters | Optimality measures | Convergence |
|-----------|---------------|------------|---------------------|-------------|
| Nesterov [17] | $\mu$-strongly convex $\varphi$ | $\mu$ | gradient mapping norm | yes |
| Liu and Xiao [7] | HEB (3) | $\kappa$ | gradient mapping norm | yes |
| Fercoq and Qu [5] | HEB (3) with $\rho = 2$ | $\kappa$ | gradient mapping norm | yes |
| Liu and Yang [8] | HEB (3) with known $\rho$ | $\kappa$ | gradient mapping norm | yes |
| Roulet and d’Aspremont [22, Proposition 3.4] | HEB (3) | $\kappa$ and $\rho$ | $\varphi(\cdot) - \varphi^*$ | no (fixed iteration) |
| Reneger and Grimmer [20] | HEB (3) | $\kappa$ and $\rho$ | $\varphi(\cdot) - \varphi^*$ | no (fixed tolerance) |
| This work (Algorithm 4) | HEB (3) | $\kappa$ and $\rho$ | gradient mapping norm (and $\varphi(\cdot) - \varphi^*$) | yes |

This paper is organized as follows. Section 2 collects preliminary facts on the gradient mapping and the Hölderian error bound condition. In particular, in Section 2.2, we deduce a lower iteration complexity bound with respect to the gradient norm for the class of smooth convex functions satisfying the Hölderian error bound condition. We review in Section 3 the regularization technique [16] preparing auxiliary results. In Section 4, we propose adaptive first-order methods and show their iteration complexity results. We show an adaptive regularization algorithm in Section 4.1 and prove the iteration complexity (2). A restart scheme of this algorithm is given in Section 4.2 and we show that it adaptively attains the nearly optimal iteration complexity under the Hölderian error bound condition. Concluding remarks are given in Section 5.

2 Preliminaries

Throughout this paper, let $\mathbb{E}$ be a finite dimensional real Hilbert space endowed with an inner product $\langle \cdot, \cdot \rangle$. We denote by $\|x\| = \langle x, x \rangle^{1/2}$ the induced norm on $\mathbb{E}$.

A convex function $f : \mathbb{E} \to \mathbb{R}$ is called $L$-smooth for $L > 0$ if $f$ is continuously differentiable and its gradient is $L$-Lipschitz continuous on $\mathbb{E}$:

$$\|\nabla f(x) - \nabla f(y)\| \leq L \|x - y\|, \quad \forall x, y \in \mathbb{E}.$$  

The following inequality is a fundamental property of $L$-smooth functions (e.g., see [15]):

$$f(x) \leq f(y) + \langle \nabla f(y), x - y \rangle + \frac{L}{2} \|x - y\|^2, \quad \forall x, y \in \mathbb{E}.$$  

(4)
We focus on the convex composite optimization problem

\[ \varphi^* = \min_x [\varphi(x) = f(x) + \Psi(x)] \]  

for an \( L_f \)-smooth convex function \( f : \mathbb{E} \to \mathbb{R} \) and a proper lower-semicontinuous convex function \( \Psi : \mathbb{E} \to \mathbb{R} \cup \{+\infty\} \). We denote by \( X^* \) the set of optimal solutions of \( \min_{x \in \mathbb{E}} \varphi(x) \):

\[ X^* = \text{Argmin}_{x \in \mathbb{E}} \varphi(x). \]

The subdifferential of \( \varphi \) at \( x \) is denoted by \( \partial \varphi(x) = \{ g \in \mathbb{E} \mid \varphi(y) \geq \varphi(x) + \langle g, y - x \rangle, \forall y \in \mathbb{E} \} \).

For the objective function \( \varphi(x) = f(x) + \Psi(x) \), we define

\[
m_L(y; x) := f(y) + \langle \nabla f(y), x - y \rangle + \frac{L}{2} \|x - y\|^2 + \Psi(x),
\]

\[ T_L(y) := \text{argmin}_{x \in \mathbb{E}} m_L(y; x) \quad (= \text{prox}_{\Psi/L}(y - L^{-1} \nabla f(y))), \]

where the minimizer \( T_L(y) \) is well-defined since \( m_L(y; \cdot) \) is strongly convex. It is assumed that \( \Psi(\cdot) \) has a “simple” structure, namely, \( T_L(\cdot) \) is moderately computable (see [19] for examples). The gradient mapping of \( \varphi \) is defined by

\[ g_L(y) := L(y - T_L(y)), \quad y \in \mathbb{E}, \quad L > 0. \]

For instance, if \( \Psi \equiv 0 \), we see that \( T_L(y) = y - \nabla f(y)/L \) and \( g_L(y) = \nabla f(y) \) hold.

Remark that the norm of \( g_L(y) \) is given by

\[ \|g_L(y)\| = L\|y - T_L(y)\|, \]

from which the quantity \( \|g_L(y)\| \) can be used as a computable optimality measure at \( y \) (see Lemma 2.1 (ii) below).

The following lemma collects basic properties on \( T_L(x) \) and \( g_L(x) \) which can be found in [2, 15, 17].

**Lemma 2.1.** Let \( \varphi = f + \Psi \) be the sum of a continuously differentiable convex function \( f : \mathbb{E} \to \mathbb{R} \) and a proper lower-semicontinuous convex function \( \Psi : \mathbb{E} \to \mathbb{R} \cup \{+\infty\} \). Then, the following assertions hold.

(i) For all \( y \in \mathbb{E} \), the map \( L \mapsto \|g_L(y)\| \) is increasing.

(ii) \( x^* \in X^* \) holds if and only if \( g_L(x^*) = 0 \).

(iii) \( \nabla f(T_L(y)) - \nabla f(y) + g_L(y) \in \partial \varphi(T_L(y)) \) for all \( y \in \mathbb{E} \). Moreover, if \( f \) is \( L_f \)-smooth, then

\[ \|\nabla f(T_L(y)) - \nabla f(y) + g_L(y)\| \leq \left( \frac{L_f}{L} + 1 \right) \|g_L(y)\|. \]

(iv) If \( y \in \mathbb{E} \) and \( L > 0 \) satisfy \( \varphi(T_L(y)) \leq m_L(y; T_L(y)) \), then we have

\[ \frac{1}{2L} \|g_L(y)\|^2 \leq \varphi(y) - \varphi(T_L(y)) \leq \varphi(y) - \varphi^*, \]

\[ \frac{1}{2L} \|g_L(y)\| \leq \text{dist}(y, X^*). \]
(v) If \( f \) is \( L_f \)-smooth, then \( \varphi(T_L(y)) \leq m_L(y;T_L(y)) \) holds for all \( y \in \mathbb{E} \) and \( L \geq L_f \).

**Proof.** (i) is proved in [17, Lemma 2].

(ii) The optimality condition of the problem \( \min_{x \in \mathbb{E}} m_L(y; x) \) is given as follows:

\[
z = T_L(y) \iff 0 \in \nabla f(y) + L(z - y) + \partial \Psi(z).
\] (6)

On the other hand, the optimality of the original problem \( \min_{x} \varphi(x) \) is characterized by

\[
z \in \text{Argmin}_{x \in \mathbb{E}} \varphi(x) \iff 0 \in \nabla f(z) + \partial \Psi(z).
\]

(Remark that \( \partial \varphi = \nabla f + \partial \Psi \) holds [21, Theorem 23.8]). Plugging \( y = z = x^* \), we see that the equivalence \( x^* \in \text{Argmin}_{x \in \mathbb{E}} \varphi(x) \iff x^* = T_L(x^*) \ (\iff g_L(x^*) = 0) \) follows.

(iii) By the optimality condition (6), we have

\[
0 \in \nabla f(y) + L(T_L(y) - y) + \partial \Psi(T_L(y)) = \nabla f(y) - g_L(y) + \partial \Psi(T_L(y)).
\] (7)

Hence,

\[
\nabla f(T_L(y)) - \nabla f(y) + g_L(y) \in \nabla f(T_L(y)) + \partial \Psi(T_L(y)) = \partial \varphi(T_L(y)).
\]

Now if \( f \) is \( L_f \)-smooth, we have

\[
\| \nabla f(T_L(y)) - \nabla f(y) \| \leq L_f \| T_L(y) - y \| = \frac{L_f}{L} \| g_L(y) \|,
\]

which yields the latter assertion of (iii).

(iv) It is shown in [2, Lemma 2.3] that, if \( \varphi(T_L(y)) \leq m_L(y; T_L(y)) \) holds, then we have

\[
\varphi(x) - \varphi(T_L(y)) \geq \frac{1}{2L} \| g_L(y) \|^2 + \langle g_L(y), x - y \rangle, \quad \forall x \in \mathbb{E}.
\]

Letting \( x := y \) shows the first assertion. On the other hand, since \( \varphi(T_L(y)) \geq \varphi^* \), letting \( x := x^* \in X^* \) gives

\[
\frac{1}{2L} \| g_L(y) \|^2 \leq \langle g_L(y), y - x^* \rangle \leq \| g_L(y) \| \| y - x^* \|, \quad \forall x^* \in X^*.
\]

Thus, we obtain \( \frac{1}{2L} \| g_L(y) \| \leq \text{dist}(y, X^*) \).

(v) Since \( f \) is \( L \)-smooth for any \( L \geq L_f \), the inequality (4) implies \( \varphi(x) \leq m_L(y; x) \) for all \( x, y \in \mathbb{E} \) and \( L \geq L_f \). \( \square \)

### 2.1 Hölderian error bound

Here we introduce the Hölderian error bound condition which is also discussed in the context of Lojasiewicz inequality [3, 9, 11].

**Definition 2.2.** Fix \( x_0 \in \mathbb{E} \). We say that \( \varphi \) satisfies the Hölderian error bound condition with coefficient \( \kappa > 0 \) and exponent \( \rho \geq 1 \) if

\[
\varphi(x) - \varphi^* \geq \kappa \text{dist}(x, X^*)^\rho, \quad \forall x \in \text{lev}_\varphi(\varphi(x_0)),
\] (8)

where \( \text{lev}_\varphi(\gamma) = \{ x \in \mathbb{E} \mid \varphi(x) \leq \gamma \} \) and \( \text{dist}(x, X^*) = \inf_{x^* \in X^*} \| x - x^* \| \).
According to [3, Theorem 3.3], the Hölderian error bound condition is satisfied for some $\kappa$ and $\rho$ if $\varphi(x)$ is a proper, lower semicontinuous, convex, coercive and subanalytic function. As subanalytic functions contain semi-algebraic ones, this condition appears in many applications including popular problems in machine learning; see, e.g., [4, 8] for related studies.

A noteworthy concept related to the Hölderian error bound condition is the Lojasiewicz gradient inequality \cite{10, 11}, which is of the form
\begin{equation}
\text{dist}(0, \partial \varphi(x)) \geq \lambda(\varphi(x) - \varphi^*)^\theta, \quad \forall x \in \text{lev}_\varphi(\varphi(x)) \setminus X^*
\end{equation}
for $\lambda > 0$ and $\theta \in [0, 1)$. In fact, these concepts (8) and (9) are equivalent for convex functions (see Remark 2.4). The Lojasiewicz gradient inequality is a powerful tool for analyzing the convergence of first-order methods as it covers wide class of applications and algorithms \cite{1, 4}.

**Lemma 2.3.** Let $\varphi : \mathbb{E} \to \mathbb{R} \cup \{+\infty\}$ be a proper lower-semicontinuous convex function. For $x_0 \in \mathbb{E}$, suppose that $\varphi$ satisfies the Hölderian error bound condition (8) with coefficient $\kappa > 0$ and exponent $\rho \geq 1$. Then, for every $x \in \text{lev}_\varphi(\varphi(x_0)) \setminus X^*$, we have
\begin{align}
\kappa \text{dist}(x, X^*)^{\rho - 1} & \leq \inf\{\|g\| : g \in \partial \varphi(x)\}, \\
\kappa^\frac{1}{\rho}(\varphi(x) - \varphi^*)^{\frac{\rho - 1}{\rho}} & \leq \inf\{\|g\| : g \in \partial \varphi(x)\}.
\end{align}

**Proof.** Let $x^*$ be the projection of $x$ onto $X^*$, so that $\|x - x^*\| = \text{dist}(x, X^*)$. For every $g \in \partial \varphi(x)$, we have
\begin{align}
\kappa \text{dist}(x, X^*)^\rho & \leq \varphi(x) - \varphi^* - \langle g, x^* - x \rangle \leq \|g\| \text{dist}(x, X^*) \leq \|g\| \frac{1}{\kappa^{1/\rho}}(\varphi(x) - \varphi^*)^{1/\rho}.
\end{align}

In particular, we obtain two inequalities
\begin{align}
\kappa \text{dist}(x, X^*)^\rho & \leq \|g\| \text{dist}(x, X^*), \\
\varphi(x) - \varphi^* & \leq \|g\| \frac{1}{\kappa^{1/\rho}}(\varphi(x) - \varphi^*)^{1/\rho}.
\end{align}

Then, since $x \notin X^*$, the assertion follows. \hfill \Box

**Remark 2.4.** The condition (10) is the Lojasiewicz gradient inequality (9) with the correspondence $\lambda = \kappa^{1/\rho}$ and $\theta = (\rho - 1)/\rho \in [0, 1)$. It is shown in [4] that the Lojasiewicz gradient inequality is essentially equivalent to the Hölderian error bound condition: If (9) holds with $\lambda = \rho \kappa^{1/\rho}$ and $\theta = (\rho - 1)/\rho$, then (8) holds (In [4, Theorem 5 (i)] set $(\kappa^{-1/\rho}, s^{1/\rho}, \varphi(x_0))$ in place of $(\varphi(s), r_0)$ and let the radius $\rho$ of $B(\bar{x}, \rho)$ to $+\infty$). \hfill \Box

### 2.2 Lower complexity bounds

Let us observe lower bounds on the iteration complexity under the Hölderian error bound condition with respect to the optimality measure $\|g_\ell(x)\|$. The lower bound is derived in the case $\Psi \equiv 0$ so that $\varphi = f$ is a smooth function and we have $g_\ell(x) = \nabla \varphi(x)$.

Given a class $\mathcal{F}$ of objective functions and an optimality measure $\delta : \mathcal{F} \times \mathbb{E} \to \mathbb{R} \cup \{+\infty\}$, the iteration complexity of a first-order method $\mathcal{M}$ applied to $\varphi \in \mathcal{F}$ for an accuracy $\varepsilon > 0$, say $C(\mathcal{M}, \varphi, \delta; \varepsilon)$, is defined as the minimal number of evaluations of a first-order oracle $(\varphi(\cdot), \nabla \varphi(\cdot))$ in the method $\mathcal{M}$ required to find a point $x \in \mathbb{E}$ satisfying $\delta(\varphi, x) \leq \varepsilon$. Then we define the iteration complexity of first-order methods associated with the class $\mathcal{F}$ with respect to the measure $\delta$ by
\begin{align}
C(\mathcal{F}, \delta; \varepsilon) := \inf_{\mathcal{M}} \sup_{\varphi \in \mathcal{F}} C(\mathcal{M}, \varphi, \delta; \varepsilon),
\end{align}
where \( \mathcal{M} \) runs all first-order methods for the class \( \mathcal{F} \) starting from some fixed initial point \( x_0 \in \mathbb{E} \).

We are interested in the iteration complexity under the following classes and measures:

- \( \mathcal{F}(x_0, R, L) \) denotes the class of \( L \)-smooth convex functions \( \varphi \) with \( X^* \neq \emptyset \) and \( \text{dist}(x_0, X^*) \leq R \), where \( X^* = \text{Argmin}_{x \in \mathbb{E}} \varphi(x) \).

- Class \( \mathcal{F}(x_0, R, L, \kappa, \rho) \): For \( R, L, \kappa > 0, \rho \geq 2 \), and \( x_0 \in \mathbb{E} \), we say that \( \varphi \) belongs to the class \( \mathcal{F}(x_0, R, L, \kappa, \rho) \) if \( \varphi \in \mathcal{F}(x_0, R, L) \) and it satisfies the Hölderian error bound condition
  \[
  \varphi(x) - \varphi^* \geq \kappa \text{dist}(x, X^*)^\rho, \quad \forall x \in \text{lev}_\varphi(\varphi(x)),
  \]
  where \( X^* = \text{Argmin}_{x \in \mathbb{E}} \varphi(x) \).

Remark that we do not consider the case \( \rho \in [1, 2) \) because any \( L \)-smooth convex function cannot admit the Hölderian error bound condition with exponent \( \rho \in (1, 2) \).

- We consider the optimality measures
  \[
  \delta^*(\varphi, x) := \varphi(x) - \inf \varphi, \quad \delta(\varphi, x) := \|\nabla \varphi(x)\|.
  \]

For the class \( \mathcal{F}(x_0, R, L) \), the following lower bound on the iteration complexity holds (by [12, Section 2.3B] applied to the class of \( L \)-smooth convex quadratic minimization):

\[
C(\mathcal{F}(x_0, R, L), \delta; \varepsilon) = \Omega \left( \min \left\{ \text{dim} \mathbb{E}, \sqrt{\frac{L R}{\varepsilon}} \right\} \right).
\]

Let us observe a lower bound on the iteration complexity for the class \( \mathcal{F}(x_0, R, L, \kappa, \rho) \).

**Proposition 2.5.** For the class \( \mathcal{F} = \mathcal{F}(x_0, R, L, \kappa, \rho) \), we have

\[
C(\mathcal{F}, \delta; \varepsilon) \geq C(\mathcal{F}, \delta^*; \varepsilon^*), \quad \text{where} \quad \varepsilon^* := \left( \frac{1}{\kappa} \right)^{\frac{1}{\rho-1}} \varepsilon^{\frac{\rho}{\rho-1}}.
\]

**Proof.** If a first-order method \( \mathcal{M} \) applied to \( \varphi \in \mathcal{F} \) finds an approximate solution \( x \in \mathbb{E} \) satisfying \( \delta(\varphi, x) \leq \varepsilon \), then Lemma 2.3 implies

\[
\delta^*(\varphi, x) = \varphi(x) - \varphi^* \leq \left( \frac{1}{\kappa} \right)^{\frac{1}{\rho-1}} \|\nabla \varphi(x)\|^{\frac{\rho}{\rho-1}} = \left( \frac{1}{\kappa} \right)^{\frac{1}{\rho-1}} \delta(\varphi, x)^{\frac{\rho}{\rho-1}} \leq \left( \frac{1}{\kappa} \right)^{\frac{1}{\rho-1}} \varepsilon^{\frac{\rho}{\rho-1}} = \varepsilon^*.
\]

Therefore, it follows that

\[
C(\mathcal{M}, \varphi, \delta; \varepsilon) \geq C(\mathcal{M}, \varphi, \delta^*; \varepsilon^*),
\]

and we obtain the assertion. \( \square \)

---

1. Suppose that \( \varphi \) is an \( L \)-smooth convex function satisfying (8) for some exponent \( \rho \in [1, 2) \). For \( \rho = 1 \), Lemma 2.3 implies \( \|\nabla \varphi(x)\| \geq \kappa \) for \( x \notin \text{Argmin} \varphi \). If \( \rho \in (0, 2) \), on the other hand, Lemmas 2.1 and 2.3 imply \( \frac{1}{\rho} \|\nabla \varphi(x)\|^2 \leq \varphi(x) - \varphi^* \leq \kappa^{-1/(\rho-1)} \|\nabla \varphi(x)\|^{\frac{2}{\rho-1}} \) for all \( x \), which yields \( \|\nabla \varphi(x)\| \geq \text{const.} \) for all \( x \notin \text{Argmin} \varphi \). This contradicts to the continuity of \( \nabla \varphi \) at points in \( \text{Argmin} \varphi \).
Under the measure $\delta^*$, the following lower bound is known \cite{13}:

\[
C(\mathcal{F}(x_0, R, L, \kappa, \rho), \delta^*; \varepsilon) = \begin{cases} 
\Omega \left( \min \left\{ \dim \mathbb{E}, \sqrt{\frac{L}{\kappa^2 \varepsilon^2}} \right\} \right) & : \rho > 2, \\
\Omega \left( \min \left\{ \dim \mathbb{E}, \sqrt{\frac{L}{\kappa \varepsilon}} \right\} \right) & : \rho = 2.
\end{cases}
\]  \quad (12)

Consequently, by Proposition 2.5, we obtain lower bounds under the gradient norm measure $\delta$:

\[
C(\mathcal{F}(x_0, R, L, \kappa, \rho), \delta; \varepsilon) = \begin{cases} 
\Omega \left( \min \left\{ \dim \mathbb{E}, \sqrt{\frac{L}{\kappa^2 \varepsilon^2}} \right\} \right) & : \rho > 2, \\
\Omega \left( \min \left\{ \dim \mathbb{E}, \sqrt{\frac{L}{\kappa \varepsilon}} \right\} \right) & : \rho = 2.
\end{cases}
\]  \quad (13)

3 Accelerated proximal gradient method applied to regularized problems

This section is devoted to review the regularization strategy \cite{8,16}, from which we construct adaptive methods in the next section. We consider to apply an accelerated proximal gradient method to the regularized problem

\[
\min_{x \in \mathbb{E}} \left[ \varphi_\sigma(x) := \varphi(x) + \frac{\sigma}{2} \|x - x_0\|^2 \right],
\]

where $x_0 \in \mathbb{E}$ is a fixed initial point and $\sigma > 0$ is a regularization parameter. Since $\varphi_\sigma$ is strongly convex, it has a unique minimizer. Let

\[
x_\sigma^* := \arg\min_{x \in \mathbb{E}} \varphi_\sigma(x), \quad \varphi_\sigma^* := \min_{x \in \mathbb{E}} \varphi_\sigma(x).
\]

We define the gradient mapping $g_\sigma^*(y)$ for the regularized function $\varphi_\sigma$ in the following manner:

\[
f_\sigma(x) := f(x) + \frac{\sigma}{2} \|x - x_0\|^2,
\]

\[
m_\sigma^*(y; x) := f_\sigma(y) + \langle \nabla f_\sigma(y), x - y \rangle + \frac{L}{2} \|x - y\|^2 + \Psi(x),
\]

\[
T_\sigma^*(y) := \arg\min_{x \in \mathbb{E}} m_\sigma^*(y; x),
\]

\[
g_\sigma^*(y) := L(y - T_\sigma^*(y)).
\]

The following relations between $\varphi_\sigma(x)$ and $\varphi(x)$ are useful.

**Lemma 3.1.**  \(i\) $\varphi_\sigma(x) \leq \varphi_\sigma(x_0)$ implies $\varphi(x) \leq \varphi(x_0)$.

\(i\) $\|x_0 - x_\sigma^*\| \leq \text{dist}(x_0, X^*)$.

\(iii\) We have $\|g_\sigma^*(y) - g_\sigma^*(y)\| \leq \sigma \|y - x_0\|$ for any $y \in \mathbb{E}$.

**Proof.** (i) is immediate by $\varphi(x) \leq \varphi_\sigma(x)$ and $\varphi_\sigma(x_0) = \varphi(x_0)$.

(ii) For any $x^* \in X^*$, the strong convexity of $\varphi_\sigma$ implies $\varphi_\sigma(x^*) \geq \varphi^* + \frac{\sigma}{2} \|x^* - x_\sigma^*\|^2$, which can be rewritten as

\[
\varphi(x^*) - \varphi(x_\sigma^*) \geq \frac{\sigma}{2}(-\|x^* - x_0\|^2 + \|x^* - x_\sigma^*\|^2 + \|x^* - x_\sigma^*\|^2).
\]
As \( \varphi(x^*) - \varphi(x^*_a) \leq 0 \), we conclude \( \|x^* - x_0\|^2 \geq \|x^*_a - x_0\|^2 + \|x^* - x^*_a\|^2 \geq \|x^*_a - x_0\|^2 \), which proves the assertion.

(iii) In general, if \( h \) is a lower-semicontinuous and \( \mu \)-strongly convex function, we have for any \( a, b \in E \) that

\[
\|x^*_a - x^*_b\| \leq \frac{\|a - b\|}{\mu}, \quad \text{where} \quad x^*_a = \arg\min_{x \in \mathbb{R}} \langle a, x \rangle + h(x), \quad x^*_b = \arg\min_{x \in \mathbb{R}} \langle b, x \rangle + h(x).
\]

This fact implies

\[
\|T_L(y) - T^\sigma_L(y)\| \leq \frac{\|\nabla f(y) - \nabla f_\sigma(y)\|}{L} = \frac{\sigma \|y - x_0\|}{L}.
\]

Therefore, we conclude (iii) because of \( \|g_L(y) - g^\sigma_L(y)\| = L \|T_L(y) - T^\sigma_L(y)\| \).

\[\Box\]

### 3.1 Accelerated proximal gradient method

We employ Nesterov’s accelerated proximal gradient method [17] for solving \( \min_{x \in E} \varphi_\sigma(x) \), by regarding the objective function as

\[
\varphi_\sigma(x) = f(x) + \Psi_\sigma(x), \quad \Psi_\sigma(x) := \Psi(x) + \frac{\sigma}{2} \|x - x_0\|^2.
\]

The analogy of the definition of \( T_L(\cdot) \) for this regularization is

\[
\tilde{T}_L(y) = \arg\min_{x \in \mathbb{E}} \left[ f(y) + \langle \nabla f(y), x - y \rangle + \frac{L}{2} \|x - y\|^2 + \Psi_\sigma(x) \right].
\]

Observe that \( \tilde{T}_L(y) = T_L^\sigma(y) \) holds (because of the identity \( m^\sigma_L(y; x) = f(y) + \langle \nabla f(y), x - y \rangle + \frac{L}{2} \|x - y\|^2 + \Psi_\sigma(x) \)). Therefore, the accelerated method \( A(x_0, L_0, \sigma) \) given in [17, Algorithm (4.9)] applied to the regularized function (14) can be described as follows: Let \( x_0 \in \mathbb{E} \), \( \psi_0(x) = \frac{1}{2} \|x - x_0\|^2 \), \( A_0 = 0 \), \( L_0 \geq L_{\min} \). Generate the sequence \( \{x_k, \psi_k, M_k, L_k, A_k\} \) by the iteration

\[
\{x_{k+1}, \psi_{k+1}, M_k, L_{k+1}, A_{k+1}\} \leftarrow \text{APGIter}_\sigma(x_k, \psi_k, L_k, A_k)
\]

for each \( k \geq 0 \). The scheme \text{APGIter} at each iteration is shown in Algorithm 1. Nesterov’s method involves the backtracking line-search procedure to adapt the Lipschitz constant \( L_f \) with the estimate \( M_k \) (and \( L_{k+1} \)) which is controlled by the parameters \( \gamma_{nc} > 1 \) and \( \gamma_{dec} \geq 1 \).

**Remark 3.2.** In one execution of the loop (Lines 3–10) in \text{APGIter}, we have three evaluations of \( \varphi(x) \) (at \( x \in \{z, T_L(z), T^\sigma_L(z)\} \)), two evaluations of \( \nabla f(x) \) (at \( x \in \{y, z\} \)), and three proximal operations \( T_L^\sigma(y), T^\sigma_L(z), T_L(z) \). There is one proximal operation to compute \( v_k \) outside the loop at Line 1. Remark that \( v_0 = x_0 \) holds and, by the recurrence formula for \( \psi_k \) at Line 13, \( v_k \) for \( k \geq 1 \) can be computed as

\[
v_k = \text{prox}_{\gamma_k \varphi}(w_k), \quad \text{where} \quad \gamma_k = \frac{A_k}{1 + \sigma A_k}, \quad w_k = x_0 - \frac{1}{1 + \sigma A_k} \sum_{i=1}^{k} \alpha_i \nabla f(x_i).
\]

\[\Box\]

---

2 By the strong convexity of \( \langle a, x \rangle + h(x) \) and \( \langle b, x \rangle + h(x) \), we have

\[
\frac{\mu}{2} \|x^*_a - x^*_b\|^2 \leq \|\langle a, x^*_a \rangle + h(x^*_a)\| - \|\langle a, x^*_b \rangle + h(x^*_b)\|,
\]

\[
\frac{\mu}{2} \|x^*_a - x^*_b\|^2 \leq \|\langle b, x^*_a \rangle + h(x^*_a)\| - \|\langle b, x^*_b \rangle + h(x^*_b)\|,
\]

respectively. Adding them implies \( \mu \|x^*_a - x^*_b\|^2 \leq \langle a - b, x^*_a - x^*_b \rangle \leq \|a - b\| \|x^*_a - x^*_b\| \).
Algorithm 1: Accelerated Proximal Gradient Iteration

\{x_{k+1}, \psi_{k+1}, M_k, L_{k+1}, A_{k+1}\} \leftarrow \text{APGIter}_\sigma(x_k, \psi_k, L_k, A_k)

**Parameters:** \(\gamma_{\text{inc}} > 1, \gamma_{\text{dec}} \geq 1, L_{\text{min}} \in (0, L_f]\).

**Input:** \(\sigma > 0, x_k \in \mathbb{E}, \psi_k : \mathbb{E} \to \mathbb{R} \cup \{+\infty\}, L_k > 0, A_k > 0\).

1. Compute \(v_k := \arg\min_{x \in \mathbb{E}} \psi_k(x)\) (cf. (16)).
2. Set \(L := L_k/\gamma_{\text{inc}}\).
3. repeat
   4. Set \(L := L\gamma_{\text{inc}}\).
   5. Find the largest root \(a > 0\) of the equation \(\frac{a^2}{A_k + a} = 2^{1+\sigma} L\).
   6. Set \(y = \frac{A_k a_k + av_k}{A_k + a}\).
   7. Compute \(z = T_{L+\sigma}^\sigma(y) = \arg\min_x [f(y) + \langle \nabla f(y), x - y \rangle + \frac{L}{2} \|x - y\|^2 + \psi(x)]\).
   8. Compute \(T_L(z)\) and \(T_{L+\sigma}(z)\).
   9. Test the conditions

\[
\begin{align*}
\langle \nabla f(y) - \nabla f(T_{L+\sigma}^\sigma(y)), y - T_{L+\sigma}^\sigma(y) \rangle & \geq \frac{1}{L} \|\nabla f(y) - \nabla f(T_{L+\sigma}^\sigma(y))\|^2, \\
\psi_{L+\sigma}(z) & \leq m_{L+\sigma}^\sigma(z; T_{L+\sigma}^\sigma(z)), \\
\varphi(T_L(z)) & \leq \varphi(z).
\end{align*}
\] (15a, 15b, 15c)

10. until the conditions in (15) hold.
11. Define \(y_k := y, M_k := L, x_{k+1} := z = T_{M_k+\sigma}^\sigma(y_k)\),
12. \(a_{k+1} := a, A_{k+1} := A_k + a_{k+1}, L_{k+1} := \max\{L_{\text{min}}, M_k/\gamma_{\text{dec}}\}\),
13. \(\psi_{k+1}(x) := \psi_k(x) + a_{k+1} [f(x_{k+1}) + \langle \nabla f(x_{k+1}), x - x_{k+1} \rangle + \psi_\sigma(x)]\).
14. Output \(\{x_{k+1}, \psi_{k+1}, M_k, L_{k+1}, A_{k+1}\}\).

**Remark 3.3.** Compared with the original Nesterov’s method, there are small modifications for our development. The update \(L_{k+1} := \max\{L_{\text{min}}, M_k/\gamma_{\text{dec}}\}\) at Line 12 is slightly different from the original one \(L_{k+1} := M_k/\gamma_{\text{dec}}\) in [17], which affects Lemma 3.5. Moreover, we have additional computations \(T_L(z)\) and \(T_{L+\sigma}^\sigma(z)\) at Line 8 in order to test the conditions (15b) and (15c). Remark that, when \(L = L_f\) is known, the computation of \(T_{L+\sigma}^\sigma(z)\) at Line 8 can be omitted as it is only used to check the second condition (15b). We let the third criterion (15c) optional; it is independent of the analysis of Algorithm 3 while we need it in Algorithm 4. The first condition (15a) is equivalent to the one in Nesterov’s method (see the proof of Lemma 5 in [17]). It will be verified in Lemmas 3.4 and 3.5 that our modification does not affect the original complexity analysis.

**Lemma 3.4.** The condition (15) of APGIter holds whenever \(L \geq L_f\).

**Proof.** The first condition (15a) is satisfied since \(f\) is \(L\)-smooth (e.g., see [15, Theorem 2.1.5]). Since \(f_\sigma\) is \((L_f + \sigma)\)-smooth, the second one (15b) holds if \(L \geq L_f\) by Lemma 2.1 (v). The third one (15c) can be verified again by Lemma 2.1 (v): If \(L \geq L_f\), we have

\[
\varphi(T_L(z)) \leq m_L(z; T_L(z)) \leq \varphi(z),
\]

where the second inequality follows from

\[
m_L(z; T_L(z)) = \min_{x \in \mathbb{E}} \left\{ f(z) + \langle \nabla f(z), x - z \rangle + \psi(x) + \frac{L}{2} \|x - z\|^2 \right\} \leq f(z) + \psi(z) = \varphi(z). \tag{17}
\]
The following lemma is given in [17, Lemma 6] while we contain its proof due to the difference in the update of $L_{k+1}$.

**Lemma 3.5.** Suppose that $L_k \leq \gamma_{inc} L_f$ holds. Then, $\text{APGIter}$ ensures $M_k \leq \gamma_{inc} L_f$ and $L_{k+1} \leq \max\{L_{min}, \frac{\gamma_{inc}}{\gamma_{dec}} L_f\} \leq \gamma_{inc} L_f$. The number of the executions of the loop (Lines 3–10) is bounded by

$$1 + \frac{\log \gamma_{dec}}{\log \gamma_{inc}} + \frac{1}{\log \gamma_{inc}} \log \left(\frac{L_{k+1}}{L_k}\right).$$

**Proof.** Let $n_k \geq 1$ be the number of inner loops so that $M_k = L_k^{\gamma_{inc}^{-n_k}}$. If $n_k = 1$, then $M_k = L \leq \gamma_{inc} L_f$. If $n_k > 1$, then $M_k \leq \gamma_{inc} L_f$ must hold because otherwise $L_k^{\gamma_{inc}^{-n_k-1}} = M_k/\gamma_{inc} > L_f$ and the $n_k$-th loop cannot occur (by Lemma 3.4). Hence, we conclude $M_k \leq \gamma_{inc} L_f$ and also $L_{k+1} = \max\{L_{min}, M/k/\gamma_{dec}\} \leq \max\{L_{min}^{\gamma_{inc}}, L_{inc}^{\gamma_{inc}}\}$. Now, the relation $M_k = L_k^{\gamma_{inc}^{-n_k}}$ implies

$$L_{k+1} = \max\{L_{min}, M/k/\gamma_{dec}\} \geq \frac{1}{\gamma_{dec}} L_k^{\gamma_{inc}^{-n_k}}.$$

Then, we have $(n_k - 1) \log \gamma_{inc} \leq \log \frac{\gamma_{dec} L_{k+1}}{L_k} = \log \gamma_{dec} + \log \frac{L_{k+1}}{L_k}$ and therefore

$$n_k \leq 1 + \frac{\log \gamma_{dec}}{\log \gamma_{inc}} + \frac{1}{\log \gamma_{inc}} \log \frac{L_{k+1}}{L_k}.$$

\[\square\]

The complexity estimate of Nesterov’s method is given as follows.

**Proposition 3.6.** Let $\{x_k, \psi_k, M_k, L_k, A_k\}$ be generated by the accelerated proximal gradient method applied to the regularized objective function (14), that is,

$$\{x_{k+1}, \psi_{k+1}, M_{k+1}, L_{k+1}, A_{k+1}\} \leftarrow \text{APGIter}_\sigma(x_k, \psi_k, L_k, A_k), \quad k = 0, 1, 2, \ldots,$$

with the initialization $x_0 \in \mathbb{E}$, $\psi_0(x) = \frac{1}{2} \|x - x_0\|^2$, $A_0 = 0$, $L_0 > 0$.

(i) If $L_0 \in [L_{min}, \gamma_{inc} L_f]$, then we have $L_{min} \leq L_k \leq M_k \leq \gamma_{inc} L_f$ for all $k \geq 0$. The total number of the executions of the loop (Lines 3–10) until the $k$-th iteration is bounded by

$$\left[1 + \frac{\log \gamma_{dec}}{\log \gamma_{inc}}\right] (k + 1) + \frac{1}{\log \gamma_{inc}} \log \frac{L_{k+1}}{L_0}.$$

(ii) For each $k \geq 1$, we have

$$A_k \geq \frac{2}{\gamma_{inc} L_f} \left[1 + \sqrt{\frac{\sigma}{2 \gamma_{inc} L_f}}\right]^{2(k-1)}.$$

(iii) $\varphi_\sigma(x_k) - \varphi^* \leq \frac{\|x_0 - x_0\|^2}{2 A_k}$ holds for all $k \geq 1$.

(iv) $\varphi(x_k) \leq \varphi(x_0)$ holds for all $k \geq 1$.

(v) For every $k \geq 1$, we have

$$\|x_k - x_0\| \leq \left(1 + \frac{1}{\sqrt{\sigma A_k}}\right) \text{dist}(x_0, X^*),$$

$$\|g_{M_k-1}(x_k)\| \leq \|g_{M_k-1}^\sigma(x_k)\| + \sigma \|x_k - x_0\| \leq \left(2 \sqrt{\frac{M_{k-1} + \sigma}{A_k}} + \sigma\right) \text{dist}(x_0, X^*).$$
Proof. (i) \( L_{\min} \leq L_k \leq M_k \) is clear by the construction. \( M_k \leq \gamma_{\text{inc}} L_f \) is obtained by applying Lemma 3.5 inductively.

Since \( \Psi_\sigma \) is \( \sigma \)-strongly convex, (ii) follows by [17, Lemma 8] applied to the objective function \( \varphi_\sigma = f + \Psi_\sigma \).

According to [17, Lemma 7], the following relations hold for all \( k \geq 0 \):

\[
\begin{align*}
A_k \varphi_\sigma(x_k) &\leq \min_{x \in \mathcal{E}} \psi_k(x), \\
\psi_k(x) &\leq A_k \varphi_\sigma(x) + \frac{1}{2} \|x - x_0\|^2, \quad \forall x \in \mathcal{E}.
\end{align*}
\]

Combining them, we obtain

\[
A_k \varphi_\sigma(x_k) \leq \min_{x \in \mathcal{E}} \left\{ A_k \varphi_\sigma(x) + \frac{1}{2} \|x - x_0\|^2 \right\}, \quad \forall k \geq 0.
\]

Taking \( x = x_\sigma^* \) on the right hand side, we obtain (iii). On the other hand, taking \( x = x_0 \) yields \( \varphi_\sigma(x_k) \leq \varphi_\sigma(x_0) \). Then Lemma 3.1 (i) gives the assertion \( \varphi(x_k) \leq \varphi(x_0) \).

(v) By the \( \sigma \)-strong convexity of \( \varphi_\sigma \) and using (iii), we have

\[
\frac{\sigma}{2} \|x_k - x_\sigma^*\|^2 \leq \varphi_\sigma(x_k) - \varphi_\sigma^* \leq \frac{\|x_0 - x_\sigma^*\|^2}{2A_k} \quad \implies \quad \|x_k - x_\sigma^*\| \leq \frac{1}{\sqrt{\sigma A_k}} \|x_0 - x_\sigma^*\|.
\]

This shows the former inequality of (v):

\[
\|x_k - x_0\| \leq \|x_k - x_\sigma^*\| + \|x_0 - x_\sigma^*\| \leq \left(1 + \frac{1}{\sqrt{\sigma A_k}}\right) \|x_0 - x_\sigma^*\| \leq \left(1 + \frac{1}{\sqrt{\sigma A_k}}\right) \text{dist}(x_0, X^*).
\]

where the last inequality follows by Lemma 3.1 (ii).

Since \( \varphi_\sigma(T_{M_k-1+\sigma}(x_k)) \leq m^\sigma_{M_k-1+\sigma}(x_k; T_{M_k-1+\sigma}^\sigma(x_k)) \) holds by (15b), Lemma 2.1 (iv) yields

\[
\frac{1}{2(M_k-1+\sigma)} \left\| g_{M_k-1+\sigma}^\sigma(x_k) \right\|^2 \leq \varphi_\sigma(x_k) - \varphi_\sigma^* \leq \frac{\|x_0 - x_\sigma^*\|^2}{2A_k} \leq \frac{\text{dist}(x_0, X^*)}{2A_k}.
\]

Thus, \( \left\| g_{M_k-1+\sigma}^\sigma(x_k) \right\| \leq \sqrt{\frac{M_k-1+\sigma}{A_k}} \text{dist}(x_0, X^*) \) holds. Consequently, using Lemma 2.1 (i) and Lemma 3.1 (iii), we obtain

\[
\left\| g_{M_k-1}(x_k) \right\| \leq \left\| g_{M_k-1+\sigma}(x_k) \right\| \leq \left( \|g_{M_k-1+\sigma}^\sigma(x_k)\| + \sigma \|x_k - x_0\| \right) \leq \sqrt{\frac{M_k-1+\sigma}{A_k}} \text{dist}(x_0, X^*) + \sigma \left(1 + \frac{1}{\sqrt{\sigma A_k}}\right) \text{dist}(x_0, X^*) \leq \left(2 \sqrt{\frac{M_k-1+\sigma}{A_k}} + \sigma\right) \text{dist}(x_0, X^*).
\]

\( \Box \)

3.2 Proximal gradient method

We end this section by preparing Algorithm 2, a basic proximal gradient descent with a backtracking strategy to estimate \( L_f \) [17, Algorithm (3.3)], which will be used in the initialization of our method. The method consists of evaluations of \( \varphi(x) \) at \( x \in \{x_k, T_L(x_k)\} \) (which can be omitted if \( L_f \) is known), one gradient evaluation \( \nabla f(x_k) \), and proximal operations \( T_L(x_k) \), for each guess \( L \) of the Lipschitz constant.
Algorithm 2: Proximal Gradient Iteration

\[ \{T_{M_k}(x_k), M_k, L_{k+1}\} \leftarrow \text{PGIter}(x_k, L_k) \]

**Parameters:** \( \gamma_{\text{inc}} > 1, \gamma_{\text{dec}} \geq 1, L_{\text{min}} \in (0, L_f) \).

**Input:** \( x_k \in E, L_k > 0 \).

1. Set \( L := L_k / \gamma_{\text{inc}} \).
2. repeat
3. Set \( L := \gamma_{\text{inc}} L \).
4. Compute \( T_L(x_k) \).
5. until the following condition holds:

\[ \varphi(T_L(x_k)) \leq m_L(x_k; T_L(x_k)). \]  \hspace{1cm} (18)

6. Define \( M_k := L, L_{k+1} := \max\{L_{\text{min}}, M_k / \gamma_{\text{dec}}\} \).
7. Output \( \{T_{M_k}(x_k), M_k, L_{k+1}\} \).

**Lemma 3.7.** Let \( \{T_{M_k}(x_k), M_k, L_{k+1}\} \) be given by PGIter\((x_k, L_k)\). Then the following assertions hold.

(i) \( \varphi(T_{M_k}(x_k)) \leq \varphi(x_k) \) holds.

(ii) If \( L_k \leq \gamma_{\text{inc}} L_f \), then we have \( M_k \leq \gamma_{\text{inc}} L_f \) and \( L_{k+1} \leq \max\{L_{\text{min}}, \gamma_{\text{dec}} L_f\} \leq \gamma_{\text{inc}} L_f \). Moreover, the number of the executions of the loop (Lines 2–5) is bounded by

\[ 1 + \frac{\log \gamma_{\text{dec}}}{\log \gamma_{\text{inc}}} + \frac{1}{\log \gamma_{\text{inc}}} \log \frac{L_{k+1}}{L_k}. \]

**Proof.** (i) The condition (18) ensures \( \varphi(T_{M_k}(x_k)) \leq m_{M_k}(x_k; T_{M_k}(x_k)) \leq \varphi(x_k) \) (recall (17) for the second inequality).

(ii) can be verified in the same way as Lemma 3.5. \( \square \)

### 4 Adaptive proximal gradient methods

In this section, we propose an adaptive proximal gradient method (Algorithm 3) and its restart scheme (Algorithm 4). We show that these two are nearly optimal for the classes \( \mathcal{F}(x_0, R, L) \) and \( \mathcal{F}(x_0, R, L, \kappa, \rho) \), respectively.

#### 4.1 Adaptive determination of regularization parameter

For solving (5) under the measure \( \|g_L(x)\| \), we propose the adaptive accelerated proximal gradient method AdaAPG shown in Algorithm 3, which can be seen as a simple extension of the regularization technique [16] introducing a guess-and-check procedure to adapt the regularization parameter \( \sigma \). The \( j \)-th outer loop of AdaAPG corresponds to applying Nesterov’s accelerated proximal gradient method to the regularized problem \( \min_{x \in E} \varphi_{\sigma_j}(x) \) where \( \sigma_j = \sigma_0 / \gamma_{\text{reg}} \quad (\gamma_{\text{reg}} > 1) \). We stop Nesterov’s method if it successfully finds an \( \varepsilon \)-solution or it iterates excessively as detected by the growth condition of \( A_{k+1} \) at Line 10. The growth of \( A_{k+1} \) is used as the criterion that the current guess of \( \sigma_j \) is not desirable and then we restart Nesterov’s method reallocating the regularization parameter as \( \sigma_{j+1} := \sigma_j / \gamma_{\text{reg}} \). The proposed method involves the parameter \( \beta \in (0, 1] \) which controls the accuracy of solving \( \min_{x} \varphi_{\sigma_j}(x) \) by Nesterov’s method (recall Proposition 3.6 (iii)).

The next lemma observes what happens if an outer loop fails to terminate the algorithm.
Algorithm 3: Adaptive Accelerated Proximal Gradient Method

AdaAPG($x_0, L_{-1}, \sigma_0, \varepsilon$)

**Parameters:** $\gamma_{\text{inc}} > 1$, $\gamma_{\text{dec}} \geq 1$, $L_{\text{min}} \in (0, L_f]$, $\gamma_{\text{reg}} > 1$, $\beta \in (0, 1]$.

**Input:** $x_0 \in \mathbb{E}$, $L_{-1} \in [L_{\text{min}}, \gamma_{\text{inc}} L_f]$, $\sigma_0 > 0$, $\varepsilon > 0$.

1: $L_0 := L_{-1}$.
2: for $j = 0, 1, 2, \ldots$ do
3:   $\sigma_j := \sigma_0 / \gamma_{\text{reg}}$.
4:   $\psi_0(x) := \frac{1}{2} \|x - x_0\|^2$, $A_0 := 0$.
5:   repeat for $k = 0, 1, 2, \ldots$ do
6:     $\{x_{k+1}, \psi_{k+1}, M_k, L_{k+1}, A_{k+1}\} \leftarrow \text{APGIter}_{\sigma_j}(x_k, \psi_k, L_k, A_k)$.
7:     if $\|g_{M_k}(x_{k+1})\| \leq \varepsilon$ then
8:       output $\{\sigma_j, x_{k+1}, T_{M_k}(x_{k+1}), M_k, L_{k+1}\}$ and terminate the algorithm.
9:     end if
10:   until $A_{k+1} \geq \frac{2(M_{k+1} + \sigma_j)}{\beta^2 \sigma_j^2}$.
11:   $L_0 := L_{k+1}$.
12: end for

**Lemma 4.1.** In AdaAPG, suppose that a $j$-th outer loop finished with the criterion $A_{k+1} \geq \frac{2(M_k + \sigma_j)}{\beta^2 \sigma_j^2}$ for some $k \geq 0$. Then we have

$$\|x_{k+1} - x_0\| \leq \left(1 + \frac{\beta}{\sqrt{2}}\right) \text{dist}(x_0, X^*),$$

$$\|g_{M_k}(x_{k+1})\| \leq (1 + \sqrt{2} \beta) \sigma_j \text{dist}(x_0, X^*).$$

Moreover, the number of inner iterations is bounded as follows.

$$k + 1 \leq 2 + \left(\sqrt{\frac{2\gamma_{\text{inc}} L_f}{\sigma_j}} + 1\right) \log \frac{\gamma_{\text{inc}} L_f + \sigma_j}{\beta \sigma_j}.$$ 

**Proof.** The bounds on $\|x_{k+1} - x_0\|$ and $\|g_{M_k}(x_{k+1})\|$ can be obtained by Proposition 3.6 (v) applying the assumption $A_{k+1} \geq \frac{2(M_k + \sigma_j)}{\beta^2 \sigma_j^2}$. To show the bound on $k + 1$, suppose $k \geq 1$ (the result is clear when $k = 0$). By the assumption on $k$ and Proposition 3.6 (i), we have

$$A_k < \frac{2(M_{k-1} + \sigma_j)}{\beta^2 \sigma_j^2} \leq \frac{2(\gamma_{\text{inc}} L_f + \sigma_j)}{\beta^2 \sigma_j^2}.$$ 

On the other hand, Proposition 3.6 (ii) implies

$$A_k \geq \frac{2}{\gamma_{\text{inc}} L_f} \left[1 + \sqrt{\frac{\sigma_j}{2\gamma_{\text{inc}} L_f}}\right]^{2(k-1)} \geq \frac{2}{\gamma_{\text{inc}} L_f} \exp\left(2(k-1)\sqrt{\frac{2 \gamma_{\text{inc}} L_f}{\sigma_j}} + 1\right),$$
where the second inequality is due to the fact\(^3\) \(1 + x \geq \exp \frac{x}{1+x} (\forall x > -1)\). Therefore,

\[
\frac{2}{\gamma_{\text{inc}} L_f} \exp \left( 2(k - 1) \frac{1}{\sqrt{2 \gamma_{\text{inc}} L_f} + 1} \right) \leq \frac{2(\gamma_{\text{inc}} L_f + \sigma_j)}{\beta^2 \sigma_j^2}
\]

\[
\implies k + 1 \leq 2 + \frac{1}{2} \left( \sqrt{\frac{2 \gamma_{\text{inc}} L_f}{\sigma_j}} + 1 \right) \log \frac{\gamma_{\text{inc}} L_f (\gamma_{\text{inc}} L_f + \sigma_j)}{\beta^2 \sigma_j^2}.
\]

The assertion follows by relaxing \(\gamma_{\text{inc}} L_f \leq \gamma_{\text{inc}} L_f + \sigma_j\).

In view of Proposition 3.6 (i) and Remark 3.2, the total number of the executions of \texttt{APGIter}, say \(N\), determines the iteration complexity of \texttt{AdaAPG}. For instance, the total number of the evaluations of \(\nabla f(\cdot)\) in \texttt{AdaAPG} is bounded by

\[
2 \left[ 1 + \frac{\log_{\text{dec}}}{\log_{\text{inc}}} \right] N + \frac{2}{\log_{\text{inc}}} \log \frac{\gamma_{\text{inc}} L_f}{L-1}.
\]

**Theorem 4.2.** In \texttt{AdaAPG}, let \(N\) be the total number of the executions of \texttt{APGIter}. Then the following assertions hold.

(i) The algorithm terminates at the \(j\)-th outer loop whenever \(\sigma_j \leq \sigma(x_0, \varepsilon)\), where

\[
\sigma(x_0, \varepsilon) := \frac{\varepsilon}{(1 + \sqrt{2}) \text{dist}(x_0, X^*)}
\]

(We let \(\sigma(x_0, \varepsilon) := +\infty\) when \(x_0 \in X^*\)). Moreover, we have

\[
\sigma_j \geq \sigma(x_0, \varepsilon)/\gamma_{\text{reg}}, \quad \forall j > 0.
\]

(ii) Suppose that the algorithm terminates at \(j = \ell\) for some \(\ell \geq 0\). Then \(N\) is at most

\[
\sqrt{\frac{2 \gamma_{\text{inc}} L_f}{\gamma_{\text{reg}}}} \frac{1}{\sqrt{\frac{1}{\sigma_\ell} - \frac{1}{\sigma_0}}} \log \frac{\gamma_{\text{inc}} L_f + \sigma_j}{\beta \sigma_\ell}
\]

\[
+ \left( 1 + \log_{\gamma_{\text{reg}}} \frac{\sigma_0}{\sigma_\ell} \right) \left( 2 + \log \frac{\gamma_{\text{inc}} L_f + \sigma_j}{\beta \sigma_\ell} \right).
\]

(iii) If \(\sigma_0 \leq \sigma(x_0, \varepsilon)\), then

\[
N \leq 2 + \left( \sqrt{\frac{2 \gamma_{\text{inc}} L_f}{\sigma_0}} + 1 \right) \log \frac{\gamma_{\text{inc}} L_f + \sigma_0}{\beta \sigma_0}.
\]

(iv) If \(\sigma_0 \geq \sigma(x_0, \varepsilon)\), then \(N\) is at most

\[
\sqrt{\frac{2 \gamma_{\text{inc}} L_f}{\gamma_{\text{reg}}}} \frac{1}{\sqrt{\frac{1}{\sigma(x_0, \varepsilon)} - \frac{1}{\sigma_0}}} \log \left( \frac{\gamma_{\text{reg}} \gamma_{\text{inc}} L_f}{\beta \sigma(x_0, \varepsilon)} + \frac{1}{\beta} \right)
\]

\[
+ \left( 2 + \log_{\gamma_{\text{reg}}} \frac{\sigma_0}{\sigma(x_0, \varepsilon)} \right) \left[ 2 + \log \left( \frac{\gamma_{\text{reg}} \gamma_{\text{inc}} L_f}{\beta \sigma(x_0, \varepsilon)} + \frac{1}{\beta} \right) \right]
\]

\[
= O \left( \frac{L_f \text{dist}(x_0, X^*)}{\varepsilon} \log \frac{L_f \text{dist}(x_0, X^*)}{\varepsilon} + \log \frac{\sigma_0 \text{dist}(x_0, X^*)}{\varepsilon} \log \frac{L_f \text{dist}(x_0, X^*)}{\varepsilon} \right). \tag{21}
\]

\(^3\) In fact, since the derivative \(\log(1+x)\) of the function \(h(x) := (1+x)\log(1+x) - x\) is increasing and vanishes at \(x = 0\), we have \(\min_{x > -1} h(x) = h(0) = 0\).
Proof. (i) By Lemma 4.1, the algorithm must terminate at the $j$-th loop whenever
\[
(1 + \sqrt{2\beta})\sigma_j \text{dist}(x_0, X^*) \leq \varepsilon, \quad \text{i.e.,} \quad \sigma_j \leq \frac{\varepsilon}{(1 + \sqrt{2\beta}) \text{dist}(x_0, X^*)} = \sigma(x_0, \varepsilon).
\]
To see the latter assertion, assume that $\sigma_j < \sigma(x_0, \varepsilon)/\gamma_{\text{reg}}$ holds for some $j > 0$. Then the previous $(j-1)$-th loop satisfies $\sigma_{j-1} < \sigma(x_0, \varepsilon)$ so that the $j$-th loop is not executed by the former assertion. This verifies the assertion (20).

(ii) Since $\sigma_\ell = \sigma_0/\gamma_{\text{reg}}^\ell$, we have $\ell = \log_{\gamma_{\text{reg}}} \sigma_0/\sigma_\ell$. Using Lemma 4.1, $N$ is bounded as follows.
\[
N \leq \sum_{j=0}^{\ell} \left[ 2 + \left( \frac{2\gamma_{\text{inc}} L_f}{\sigma_j} + 1 \right) \log \frac{\gamma_{\text{inc}} L_f + \sigma_j}{\beta \sigma_j} \right]
\leq 2(\ell + 1) + \sqrt{2\gamma_{\text{inc}} L_f} \log \frac{\gamma_{\text{inc}} L_f + \sigma_\ell}{\beta \sigma_\ell} \sum_{j=0}^{\ell} \left[ \frac{1}{\sigma_j} + (\ell + 1) \frac{1}{\sigma_j} \right],
\]
where the second inequality is due to $\sigma_j \geq \sigma_\ell$ ($\forall j \leq \ell$). Note that
\[
\sum_{j=0}^{\ell} \sqrt{\frac{1}{\sigma_j}} = \sum_{j=0}^{\ell} \sqrt{\frac{1}{\sigma_0/\gamma_{\text{reg}}^j}} = \sqrt{\frac{1}{\sigma_0}} \sum_{j=0}^{\ell} \sqrt{\gamma_{\text{reg}}^j} = \frac{1}{\sigma_0} \sqrt{\gamma_{\text{reg}}^{\ell+1} - 1} \sqrt{\gamma_{\text{reg}} - 1}
= \sqrt{\frac{1}{\gamma_{\text{reg}}}} \sqrt{\frac{1}{\sigma_0}} \left[ \sqrt{\gamma_{\text{reg}}} \sqrt{\frac{1}{\sigma_\ell}} - \sqrt{\frac{1}{\sigma_0}} \right].
\]
Therefore, we see that
\[
N \leq (\ell + 1) \left( 2 + \log \frac{\gamma_{\text{inc}} L_f + \sigma_\ell}{\beta \sigma_\ell} \right) + \sqrt{2\gamma_{\text{inc}} L_f} \log \frac{\gamma_{\text{inc}} L_f + \sigma_\ell}{\beta \sigma_\ell} \frac{1}{\sqrt{\gamma_{\text{reg}} - 1}} \left[ \sqrt{\gamma_{\text{reg}}} \sqrt{\frac{1}{\sigma_\ell}} - \sqrt{\frac{1}{\sigma_0}} \right].
\]
The assertion follows by substituting $\ell = \log_{\gamma_{\text{reg}}} \sigma_0/\sigma_\ell$.

In view of (i), the assertions (iii) and (iv) follow by applying (ii) with $\sigma_\ell = \sigma_0$ and $\sigma_\ell \geq \sigma(x_0, \varepsilon)/\gamma_{\text{reg}}$, respectively. The big-$O$ expression (21) is obtained by substituting the definition of $\sigma(x_0, \varepsilon)$.

If $\sigma_0$ is chosen appropriately, then the complexity estimates in Theorem 4.2 (iii) and (vi) match the lower complexity bound (11) for the class $\mathcal{F}(x_0, R, L)$, up to a logarithmic factor. Nesterov’s regularization technique [16] essentially corresponds to the ideal choice $\sigma_0 = \sigma(x_0, \varepsilon)$, which requires dist($x_0, X^*$) to be known. Here we show a simple example to choose $\sigma_0$ so that AdaAPG attains the near optimality without knowing dist($x_0, X^*$).

**Corollary 4.3.** Given $x_0 \in \mathbb{E}$ and $L_{-1} \in [L_{\text{min}}, \gamma_{\text{inc}} L_f]$, apply $\{T_M(x_0), M, L\} \leftarrow \text{PGiter}(x_0, L_{-1})$. For any $\varepsilon > 0$ such that $\|g_M(x_0)\| \geq \varepsilon$, choose $\sigma_0$ from the interval
\[
\sigma_0 \in \left[ \frac{2\varepsilon M}{(1 + \sqrt{2\beta}) \|g_M(x_0)\|}, \frac{2M}{1 + \sqrt{2\beta}} \right].
\]
Then we have
\[
\sigma(x_0, \varepsilon) \leq \sigma_0 \leq \frac{2\gamma_{\text{inc}} L_f}{1 + \sqrt{2\beta}}.
\]
Consequently, AdaAPG($x_0, L_{-1}, \sigma_0, \varepsilon$) finds $x_k \in \mathbb{E}$ and $M_k > 0$ satisfying $\|g_{M_k}(x_k)\| \leq \varepsilon$ with the iteration complexity at most
\[
O \left( \sqrt{\frac{L_f \text{dist}(x_0, X^*)}{\varepsilon}} \log \frac{L_f \text{dist}(x_0, X^*)}{\varepsilon} \right).
\]
Proof. Since $\varphi(T_M(x_0)) \leq m_M(x_0; T_M(x_0))$ holds by the condition (18) in PGIter, Lemma 2.1 (iv) implies
\[
\text{dist}(x_0, X^*) \geq \frac{1}{2M} \| g_M(x_0) \| \geq \frac{1}{2M} \varepsilon \geq \frac{1}{2\gamma_{\text{inc}} L_f} \varepsilon,
\]
where the last inequality follows from Lemma 3.7 (ii). This can be rewritten as
\[
\sigma(x_0, \varepsilon) \equiv \frac{\varepsilon}{(1 + \sqrt{2}\beta) \text{dist}(x_0, X^*)} \leq \frac{2\varepsilon M}{(1 + \sqrt{2}\beta) \| g_M(x_0) \|} \leq \frac{2M}{1 + \sqrt{2}\beta} \leq 2\gamma_{\text{inc}} L_f.
\]
Therefore, (22) implies (23). In particular, we can apply Theorem 4.2 (iv) to obtain the complexity bound (21) whose second term is dominated by the first one due to the upper bound (23) of $\sigma_0$. \qed

Finally, we observe on the convergence of the proposed method. Let us consider the execution of AdaAPG with $\varepsilon = 0$ which is possibly an infinite step algorithm. Then the choice
\[
\sigma_0 := 2M/(1 + 2\sqrt{\beta})
\]
given in Corollary 4.3 ensures the nearly optimal complexity bound (24) for every $\varepsilon \in (0, \| g_M(x_0) \|_*)$. This means that, with this choice of $\sigma_0$, the algorithm AdaAPG with $\varepsilon = 0$ yields a nearly optimal convergence with respect to $\| g_L(x) \|$.

4.2 Adaptive restart algorithm under Hölderian error bound condition

In this section, given an initial point $x^{(0)} \in \mathbb{E}$, we assume that the objective function $\varphi$ admits the Hölderian error bound condition
\[
\varphi(x) - \varphi^* \geq \kappa \text{dist}(x, X^*)^\rho, \quad \forall x \in \text{lev}_\varphi(\varphi(x^{(0)})),
\]
for some $\kappa > 0$ and $\rho \geq 1$. For this case, we propose the restart scheme rAdaAPG described in Algorithm 4. Namely, given a current solution $x^{(t)}$, we apply a proximal gradient iteration $x^{(t)} := T_{M(t)}(x^{(t)})$ from which we start AdaAPG to find the next $x^{(t+1)}$ reducing the gradient mapping norm at the ratio $\theta \in (0, 1)$:
\[
\| g_{M^{(t+1)}}(x^{(t+1)}) \| \leq \theta \| g_{M^{(t)}}(x^{(t)}) \|.
\]
Remarkably, the regularization parameter $\sigma^{(t)}$ is input to AdaAPG which adaptively finds the next $\sigma^{(t+1)}$. Therefore, the next $x^{(t+1)}$ can be seen as an approximate solution to the regularized problem
\[
\min_{x \in \mathbb{E}} \left[ \varphi(x) + \frac{\sigma^{(t+1)}}{2} \| x - x_+^{(t)} \|^2 \right]
\]
computed by an accelerated proximal gradient method. Finally, we note that the initial regularization parameter $\sigma^{(0)}$ may be determined depending on the result of Line 1, as observed in Corollary 4.5.

4.2.1 Iteration complexity results and near optimality

To show the iteration complexity result, remark that the total number $N$ of the executions of APGIter determines the complexity of rAdaAPG. For instance, the total number of the evaluations of $\nabla f(\cdot)$ in rAdaAPG can be bounded by (recall Proposition 3.6 (i), Lemma 3.7 (ii), and Remark 3.2)
\[
\left[ 1 + \frac{\log \gamma_{\text{dec}}}{\log \gamma_{\text{inc}}} \right] (2N + 1) + \frac{2}{\log \gamma_{\text{inc}}} \log \frac{\gamma_{\text{inc}} L_f}{L(-1)}.
\]
Algorithm 4: Restart Scheme for Adaptive Accelerated Proximal Gradient Method

\[ r_{\text{AdaAPG}}(x^{(0)}, L^{-1}, \sigma^{(0)}, \varepsilon) \]

Parameters:
- \( \gamma_{\text{inc}} > 1 \), \( \gamma_{\text{dec}} \geq 1 \), \( L_{\min} \in (0, L_f] \) (for backtracking line-search);
- \( \gamma_{\text{reg}} > 1 \) (the ratio to reallocate the regularization parameter);
- \( \beta \in (0, 1] \) (controls the accuracy applying accelerated proximal gradient method);
- \( \theta \in (0, 1) \) (the ratio reducing the residue per iteration).

Input: \( x^{(0)} \in \mathbb{E}, L^{-1} \in [L_{\min}, \gamma_{\text{inc}}L_f], \sigma^{(0)} > 0, \varepsilon > 0. \)

1. Compute \( \{x_+^{(0)}, M^{(0)}, L^{(0)}\} \leftarrow \text{PGIter}(x^{(0)}, L^{(-1)}) \).
2. for \( t = 0, 1, 2, \ldots \) do
   3. if \( \|g_{M^{(t)}}(x^{(t)})\| \leq \varepsilon \) then output \( \{x^{(t)}, M^{(t)}, x_+^{(t)}\} \) and terminate the algorithm.
   4. \( \varepsilon^{(t)} := \theta \|g_{M^{(t)}}(x^{(t)})\| \).
   5. \( \{\sigma^{(t+1)}, x^{(t+1)}, x_+^{(t+1)}, M^{(t+1)}, L^{(t+1)}\} \leftarrow \text{AdaAPG}(x_+^{(t)}, L^{(t)}, \sigma^{(t)}, \varepsilon^{(t)}) \)
   6. (with testing the optional condition (15c) of APGIter).
3. end for

We focus on the bound on \( N \) in the remaining of this section.

To describe the iteration complexity bounds, we define \( N(\varepsilon, \sigma_*, C) \) and \( \bar{\sigma} \) as follows. Given \( \varepsilon, \sigma_*, C > 0 \), let \( N(\varepsilon, \sigma_*, C) := 0 \) if \( \|g_{M^{(0)}}(x^{(0)})\| \leq \varepsilon \) and otherwise

\[
N(\varepsilon, \sigma_*, C) := \left( 1 + \log_{1/\theta} \frac{\|g_{M^{(0)}}(x^{(0)})\|}{\varepsilon} + \log_{\gamma_{\text{reg}}} \frac{\sigma^{(0)}}{\sigma_*} \right) \left( 2 + \log \frac{\gamma_{\text{inc}}L_f + \sigma_*}{\beta \sigma_*} \right) \\
+ \sqrt{2\gamma_{\text{inc}}L_f} \sqrt{\gamma_{\text{reg}} - 1} \left[ \sqrt{\frac{1}{\sigma_*} - \sqrt{\frac{1}{\sigma^{(0)}}}} \log \frac{\gamma_{\text{inc}}L_f + \sigma_*}{\beta \sigma_*} \right] \\
+ C \sqrt{2\gamma_{\text{inc}}L_f} \log \frac{\gamma_{\text{inc}}L_f + \sigma_*}{\beta \sigma_*}.
\]

Moreover, we define

\[
\bar{\sigma} = \begin{cases} 
\theta \frac{L_f}{L_{\min}} + 1 & \left( \frac{L_f}{L_{\min}} + 1 \right)^{1-\frac{1}{\rho-1}} \varepsilon^{1-\frac{2}{\rho-1}} \quad \text{(if } \rho \geq 2), \\
1 + \sqrt{2\beta} \frac{L_f}{\sqrt{L_{\min}}} & \left( \varphi(x^{(0)}) - \varphi^* \right)^{-\frac{2}{\rho}} \quad \text{(if } 1 \leq \rho < 2). 
\end{cases}
\]

The next theorem provides the descriptions of the iteration complexity bounds which have complicated forms in order to express the effects of parameters. A simplified form is presented in Corollary 4.5. Their proofs are given in Section 4.2.2.

**Theorem 4.4.** Assume that the Hölderian error bound condition (25) holds. In \( r_{\text{AdaAPG}} \), let \( N \) be the total number of the executions of APGIter. Denote

\[
\sigma_* := \begin{cases} 
\sigma^{(0)} & \text{(if } \sigma^{(0)} \geq \bar{\sigma}), \\
\frac{\bar{\sigma}}{\gamma_{\text{reg}}} & \text{(otherwise),}
\end{cases}
\]

for \( \bar{\sigma} \) defined in (27). Also, let \( N(\cdot, \cdot, \cdot) \) be defined by (26). Then the following assertions hold.

(i) If \( \rho = 2 \), then \( N \leq N(\varepsilon, \sigma_*, C) \) holds with

\[
C = \sqrt{\frac{1}{\sigma_*}} \left( 1 + \log_{1/\theta} \frac{\|g_{M^{(0)}}(x^{(0)})\|}{\varepsilon} \right).
\]

18
(ii) Suppose $\rho > 2$. If $\sigma^{(0)} \geq \bar{\sigma}$, then $N \leq N(\varepsilon, \sigma, C)$ holds with

$$C = \sqrt{\frac{1}{\sigma^{(0)}}} \left( 1 + \frac{\rho - 1}{\rho - 2} \log_{1/\theta} \frac{\sigma^{(0)}}{\min(\sigma^{(0)}, \sigma(0))} \right) + \frac{\sqrt{\text{reg}}}{1 - \sqrt{\theta^{\rho-2}}} \left( \sqrt{\frac{1}{\sigma}} - \sqrt{\theta^{\rho-2}} \frac{1}{\sigma^{(0)}} \right),$$

where $\sigma^{(0)} := \frac{\theta}{1+\sqrt{2} \beta} \cdot \kappa^{\frac{1}{\rho}} \left( \frac{L_f}{T_{\text{min}}} + 1 \right)^{-\frac{1}{\rho-1}} \|g_{M^{(0)}(x^{(0)})}\|_{\sigma^{(0)}}$. Otherwise, it follows $\sigma^{(t)} = \sigma^{(0)}$ ($\forall t \geq 0$) and $N \leq N(\varepsilon, \sigma^{(0)}, C)$ holds with

$$C = \sqrt{\frac{1}{\sigma^{(0)}}} \left( 1 + \log_{1/\theta} \frac{\|g_{M^{(0)}(x^{(0)})}\|}{\varepsilon} \right).$$

(iii) Suppose $\rho \in (1, 2)$. Then we have

$$N \leq 1 + N(\max(\varepsilon, \varepsilon_*), \sigma, C) + \left( \log \frac{1}{\rho - 1} \right)^{-1} \left( \log \log \frac{\varepsilon_*}{\theta^{\rho} \min(\varepsilon, \varepsilon_*)} - \log \log \frac{1}{\theta^{\rho}} \right),$$

where

$$\varepsilon_* = \left( 1 + \sqrt{2} \theta^{-1} (\gamma_{\text{inc}} L_f + \sigma^{(0)}) \right)^{-\frac{1}{\rho-1}} \kappa^{-\frac{1}{\rho}} \left( \frac{L_f}{T_{\text{min}}} + 1 \right)^{-\frac{1}{\rho-1}},$$

$$C = \sqrt{\frac{1}{\sigma_*}} \left( 1 + \log_{1/\theta} \frac{\|g_{M^{(0)}(x^{(0)})}\|}{\max(\varepsilon, \varepsilon_*)} \right).$$

(iv) If $\rho = 1$, then we have

$$N \leq 1 + N(\max(\varepsilon, \varepsilon_*), \sigma, C),$$

where

$$\varepsilon_* = \kappa \left( \frac{L_f}{T_{\text{min}}} + 1 \right)^{-1}, \quad C = \sqrt{\frac{1}{\sigma_*}} \left( 1 + \log_{1/\theta} \frac{\|g_{M^{(0)}(x^{(0)})}\|}{\max(\varepsilon, \varepsilon_*)} \right).$$

Moreover, if $\varepsilon < \varepsilon_*$, then $x^{(t)}_{+}$ in the output of the algorithm must be an optimal solution to the original problem (5).

**Corollary 4.5.** Let $x^{(0)} \in \mathbb{E}$ and $L^{(-1)} \in [L_{\text{min}}, \gamma_{\text{inc}} L_f]$. Assume that the Hölderian error bound condition (25) holds. After the initialization step (Line 1) in rAdaAPG, determine $\sigma^{(0)}$ by

$$\sigma^{(0)} := \frac{2 \varepsilon^{(0)} M}{(1 + \sqrt{2} \beta) \|g_{M(x^{(0)})}\|}, \quad \text{where} \quad \{T_M(x^{(0)}_+, M, L) \leftarrow \text{PGIter}(x^{(0)}_+, L^{(0)}). \quad (31)$$

Then, rAdaAPG($x^{(0)}, L^{(-1)}, \sigma^{(0)}, \varepsilon$) finds $x^{(t)} \in \mathbb{E}$ and $M^{(t)} > 0$ such that $\|g_{M^{(t)}(x^{(t)})}\| \leq \varepsilon$ with iteration complexity at most the following quantities, where we denote

$$g_0 := g_{M^{(0)}(x^{(0)})}, \quad \Delta_0 := \varphi(x^{(0)}) - \varphi^*,$$
\( \varepsilon_* \) is defined by (30), and we regard \( \theta, \gamma_{\text{inc}}, \gamma_{\text{reg}}, \beta, \frac{L_f}{L_{\min}} \) as constants.

\[
\begin{align*}
O \left( \log \frac{\|g_0\|}{\varepsilon} + \sqrt{\frac{L_f}{\kappa \rho_{\min}} \frac{\rho - 1}{\rho - 2}} \log \frac{L_f}{\varepsilon^{\rho - 1}} \right) & \quad (\rho > 2), \\
O \left( \frac{L_f}{\kappa} \log \frac{L_f}{\varepsilon^{\rho - 1}} \right) & \quad (\rho = 2), \\
O \left( \sqrt{\frac{L_f \Delta_0}{\kappa \rho}} \log \frac{\|g_0\|}{\varepsilon} + (\log \frac{1}{\rho - 1})^{-1} \log \frac{\Delta_0 L_f}{\varepsilon^{\rho - 1}} \right) & \quad (\rho \in (1, 2), \varepsilon \leq \varepsilon_*), \\
O \left( \sqrt{\frac{L_f \Delta_0}{\kappa \rho}} \log \frac{\|g_0\|}{\varepsilon} \right) & \quad (\rho \in (1, 2), \varepsilon \geq \varepsilon_*), \\
O \left( \sqrt{\frac{L_f \Delta_0}{\kappa \rho}} \log \frac{\|g_0\|}{\max(\kappa, \varepsilon)} \right) & \quad (\rho = 1).
\end{align*}
\]

Let us observe the consequences of Corollary 4.5. Notice that the iteration complexity bounds (32) in the cases \( \rho = 2 \) and \( \rho > 2 \) match the lower bounds (13) up to a logarithmic factor. Therefore, rAdaAPG achieves the near optimality for the class \( \mathcal{F}(x_0, R, L, \kappa, \rho) \).

Note that \( \sigma^{(0)} \) defined in (31) is independent of \( \varepsilon \). Therefore, if we consider rAdaAPG with \( \varepsilon = 0 \), the algorithm ensures the above iteration complexity for every \( \varepsilon \) so that we obtain a convergence result.

The algorithm rAdaAPG with \( \varepsilon = 0 \) can also provide an iteration complexity result with respect to the measure \( \varphi(\cdot) - \varphi^* \). As we prove the inequality (35), the following relation holds if \( \rho \neq 1 \).

\[
\varphi(x_+^{(t)}) - \varphi^* \leq \frac{1}{\kappa^{\rho - 1}} \left( \frac{L_f}{L_{\min}} + 1 \right)^{\rho - 1} \frac{\|g_{M(t)}(x^{(t)})\|}{\varepsilon^{\rho - 1}}.
\]

This means that, given \( \delta > 0 \), we have the following implication:

\[
\|g_{M(t)}(x^{(t)})\| \leq \varepsilon := \kappa^{\frac{1}{\rho - 1}} \left( \frac{L_f}{L_{\min}} + 1 \right)^{-1} \delta^{\frac{1}{\rho - 1}} \quad \Rightarrow \quad \varphi(x_+^{(t)}) - \varphi^* \leq \delta.
\]

Substituting this \( \varepsilon \) to our complexity bound (32), we also obtain an iteration complexity bound under the measure \( \varphi(\cdot) - \varphi^* \) which is nearly optimal in view of the lower complexity bound (12). Although it enjoys an adaptive and nearly optimal convergence, the proposed method does not provide a stopping criterion for the measure \( \varphi(\cdot) - \varphi^* \) since the right hand side of (33) is not verifiable unless we know \( \kappa \) and \( \rho \).

### 4.2.2 Proof of the main results

Here we complete the proofs of Theorem 4.4 and Corollary 4.5. We prepare some lemmas below.

**Lemma 4.6.** Assume that the Hölderian error bound condition (25) holds. In the execution of rAdaAPG, the following assertions hold.

(i) \( L^{(t)}(t) \in [L_{\min}, \gamma_{\text{inc}} L_f] \) for all \( t \geq 0 \).

(ii) \( \varphi(x_+^{(t+1)}) \leq \varphi(x_+^{(t)}) \leq \cdots \leq \varphi(x_+^{(0)}) \leq \varphi(x^{(0)}) \) for all \( t \geq 0 \).

(iii) \( t \leq \log \frac{1}{\theta} \left( \frac{\|g_{M(0)}(x^{(0)})\|}{\|g_{M(t)}(x^{(t)})\|} \right) \) for each \( t \geq 0 \).
(iv) Whenever \( x_+^{(t)} \notin X^* \), we have
\[
\text{dist}(x_+^{(t)}, X^*)^{\rho-1} \leq \frac{1}{\kappa} \left( \frac{L_f}{L_{\min}} + 1 \right) \left\| g_{M(t)}(x_+^{(t)}) \right\|, \tag{34}
\]
\[
(\varphi(x_+^{(t)}) - \varphi^*)^{\rho-1} \leq \frac{1}{\kappa} \left( \frac{L_f}{L_{\min}} + 1 \right)^{\rho} \left\| g_{M(t)}(x_+^{(t)}) \right\|^\rho. \tag{35}
\]

Proof. (i) Since \( L^{-1}(\cdot) \in [L_{\min}, \gamma_{\text{inc}} L_f] \), it follows \( L(0), M(0) \in [L_{\min}, \gamma_{\text{inc}} L_f] \) by Lemma 3.7 (ii). Then, using Proposition 3.6 (i) inductively, we obtain (i).

(ii) For \( t = 0 \), we have \( \varphi(x_+^{(0)}) = \varphi(T_{M(0)}(x_0^{(0)})) \leq \varphi(x_0^{(0)}) \) by Lemma 3.7 (i). Moreover, according to the criterion (35c) and Proposition 3.6 (iv) applied to the subroutine \( \text{AdaAPG} \) in \( \text{rAdaAPG} \) satisfies
\[
\varphi(x_+^{(t+1)}) \leq \varphi(x_+^{(t+1)}) \quad \text{and} \quad \varphi(x_+^{(t+1)}) \leq \varphi(x_+^{(t)}),
\]
respectively. This shows \( \varphi(x_+^{(t+1)}) \leq \varphi(x_+^{(t)}) \).

(iii) Since the recurrence \( \varepsilon^{(t)} / \theta = \left\| g_{M(t)}(x_+^{(t)}) \right\| \leq \varepsilon^{(t-1)} \) holds for \( t \geq 1 \), we have \( \varepsilon^{(0)} \geq \varepsilon^{(t)}/\theta^t \) for each \( t \geq 0 \). Therefore,
\[
t \leq \log_{1/\theta} \varepsilon^{(t)} = \log_{1/\theta} \frac{\left\| g_{M(0)}(x_0^{(0)}) \right\|}{\left\| g_{M(t)}(x_+^{(t)}) \right\|},
\]
(iv) Since \( x_+^{(t)} = T_{M(t)}(x_+^{(t)}) \), Lemma 2.1 (iii) implies that \( g_t := \nabla f(x_+^{(t)}) - \nabla f(x_+^{(t)}) + g_{M(t)}(x_+^{(t)}) \) belongs to \( \partial \varphi(x_+^{(t)}) \). Then, Lemma 2.3 shows (note that \( x_+^{(t)} \) belongs to \( \text{lev} \varphi(x_0^{(0)}) \setminus X^* \) by (ii))
\[
\kappa \text{dist}(x_+^{(t)}, X^*)^{\rho-1} \leq \| g_t \| \leq \left( \frac{L_f}{M(t)} + 1 \right) \left\| g_{M(t)}(x_+^{(t)}) \right\| \leq \left( \frac{L_f}{L_{\min}} + 1 \right) \left\| g_{M(t)}(x_+^{(t)}) \right\|,
\]
where the second inequality is due to Lemma 2.1 (iii) and the last follows by (i). This shows the assertion (34). Similarly, (35) can be obtained using (10). \( \square \)

The following lemma plays an essential role to derive our iteration complexity results.

Lemma 4.7. Let \( N^{(t)} \) be the number of the executions of \( \text{APGIter} \) at the \( t \)-th outer loop of \( \text{rAdaAPG} \). Assume that, for some \( T_\ast \geq 0 \), \( \sigma_\ast > 0 \), and \( \varepsilon_\ast > 0 \), we have
\[
\sigma^{(t+1)} \geq \sigma_\ast \quad (t = 0, \ldots, T_\ast) \quad \text{and} \quad \left\| g_{M(T_\ast)}(x^{(T_\ast)}) \right\| \geq \varepsilon_\ast.
\]
Then, under the definition (26) of \( N(\cdot, \cdot, \cdot) \), the following inequality holds.
\[
\sum_{t=0}^{T_\ast} N^{(t)} \leq N(\varepsilon_\ast, \sigma_\ast, C) \leq N(\varepsilon_\ast, \sigma_\ast, C_\ast),
\]
where
\[
C := \sum_{t=0}^{T_\ast} \sqrt{\frac{1}{\sigma^{(t+1)}}} \leq C_\ast := \sqrt{\frac{1}{\sigma_\ast}} \left( 1 + \log_{1/\theta} \frac{\left\| g_{M(0)}(x_0^{(0)}) \right\|}{\varepsilon_\ast} \right).
\]
Proof. Since $\sigma^{(t+1)} \geq \sigma_*$ for each $t = 0, \ldots, T_*$, Theorem 4.2 (ii) gives the following bound for $t = 0, \ldots, T_*$:

$$N^{(t)} \leq \left(1 + \log_{\gamma_{\text{reg}}} \frac{\sigma^{(t)}}{\sigma^{(t+1)}}\right) \left(2 + \log \frac{\gamma_{\text{inc}} L_f + \sigma^{(t+1)}}{\beta \sigma^{(t+1)}}\right)$$

$$+ \frac{\sqrt{2 \gamma_{\text{inc}} L_f}}{\sqrt{\gamma_{\text{reg}} - 1}} \left[\sqrt{\gamma_{\text{reg}}} \sqrt{\frac{1}{\sigma^{(t+1)}}} - \sqrt{\frac{1}{\sigma^{(t)}}}\right] \log \frac{\gamma_{\text{inc}} L_f + \sigma^{(t+1)}}{\beta \sigma^{(t+1)}}$$

$$\leq \left(1 + \log_{\gamma_{\text{reg}}} \frac{\sigma^{(t)}}{\sigma^{(t+1)}}\right) \left(2 + \log \frac{\gamma_{\text{inc}} L_f + \sigma_*}{\beta \sigma_*}\right)$$

$$+ \frac{\sqrt{2 \gamma_{\text{inc}} L_f}}{\sqrt{\gamma_{\text{reg}} - 1}} \left[\sqrt{\gamma_{\text{reg}}} \sqrt{\frac{1}{\sigma^{(t+1)}}} - \sqrt{\frac{1}{\sigma^{(t)}}}\right] \log \frac{\gamma_{\text{inc}} L_f + \sigma_*}{\beta \sigma_*}.$$ 

By Lemma 4.6 (iii), $T_*$ is bounded by

$$T_* \leq \log_{1/\theta} \frac{\|g_{M^{(0)}}(x^{(0)})\|}{\|g_{M(T_*)}(x(T_*))\|} \leq \log_{1/\theta} \frac{\|g_{M^{(0)}}(x^{(0)})\|}{\varepsilon_*}.$$ 

To estimate the sum $\sum_{t=0}^{T_*} N^{(t)}$, note that

$$\sum_{t=0}^{T_*} \left(1 + \log_{\gamma_{\text{reg}}} \frac{\sigma^{(t)}}{\sigma^{(t+1)}}\right) = 1 + T_* + \log_{\gamma_{\text{reg}}} \frac{\sigma^{(0)}}{\sigma^{(T_*+1)}} \leq 1 + \log_{1/\theta} \frac{\|g_{M^{(0)}}(x^{(0)})\|}{\varepsilon_*} + \log_{\gamma_{\text{reg}}} \frac{\sigma^{(0)}}{\sigma_*},$$

and

$$\sum_{t=0}^{T_*} \left[\sqrt{\gamma_{\text{reg}}} \sqrt{\frac{1}{\sigma^{(t+1)}}} - \sqrt{\frac{1}{\sigma^{(t)}}}\right] = (\sqrt{\gamma_{\text{reg}}} - 1) \sum_{t=0}^{T_*} \sqrt{\frac{1}{\sigma^{(t+1)}}} + \sum_{t=0}^{T_*} \left[\sqrt{\frac{1}{\sigma^{(t+1)}}} - \sqrt{\frac{1}{\sigma^{(t)}}}\right]$$

$$= (\sqrt{\gamma_{\text{reg}}} - 1) \sum_{t=0}^{T_*} \sqrt{\frac{1}{\sigma^{(t+1)}}} + \sqrt{\frac{1}{\sigma^{(T_*+1)}}} - \sqrt{\frac{1}{\sigma^{(0)}}}.$$ 

Therefore, $\sum_{t=0}^{T_*} N^{(t)}$ is bounded by

$$\sum_{t=0}^{T_*} N^{(t)} \leq \left(1 + \log_{1/\theta} \frac{\|g_{M^{(0)}}(x^{(0)})\|}{\varepsilon_*} + \log_{\gamma_{\text{reg}}} \frac{\sigma^{(0)}}{\sigma_*}\right) \left(2 + \log \frac{\gamma_{\text{inc}} L_f + \sigma_*}{\beta \sigma_*}\right)$$

$$+ \frac{\sqrt{2 \gamma_{\text{inc}} L_f}}{\sqrt{\gamma_{\text{reg}} - 1}} \left[\sqrt{\frac{1}{\sigma_*}} - \sqrt{\frac{1}{\sigma^{(0)}}}\right] \log \frac{\gamma_{\text{inc}} L_f + \sigma_*}{\beta \sigma_*}$$

$$+ \frac{\sqrt{2 \gamma_{\text{inc}} L_f}}{\sqrt{\gamma_{\text{reg}} - 1}} \sum_{t=0}^{T_*} \frac{1}{\sigma^{(t+1)}} \log \frac{\gamma_{\text{inc}} L_f + \sigma_*}{\beta \sigma_*}$$

$$= N(\varepsilon_*, \sigma_*, C).$$

Finally, $C$ has the following bound:

$$C = \sum_{t=0}^{T_*} \sqrt{\frac{1}{\sigma^{(t+1)}}} \leq \sqrt{\frac{1}{\sigma_*}} (1 + T_*) \leq \sqrt{\frac{1}{\sigma_*}} \left(1 + \log_{1/\theta} \frac{\|g_{M^{(0)}}(x^{(0)})\|}{\varepsilon_*}\right) = C_*,$$

which also concludes $N(\varepsilon_*, \sigma_*, C) \leq N(\varepsilon_*, \sigma_*, C_*).$
In view of this lemma, the complexity analysis boils down to analyze lower bounds of \( \sigma^{(t)} \) as we discuss next.

**Lemma 4.8.** Assume that the Hölderian error bound condition (25) holds. Suppose that \( r \text{AdaAPG} \) terminated with the stopping criterion at the \((T+1)\)-th outer loop for some \( T \geq 0 \). Let \( \bar{\sigma} \) be defined by (27).

(i) For each \( t = 0, \ldots, T \), we have

\[
\begin{align*}
\sigma^{(t+1)} \left\{ \begin{array}{ll}
= \sigma^{(t)} & (\sigma^{(t)} \leq \sigma(x^+_+, \varepsilon^{(t)})), \\
\geq \sigma(x^+_+, \varepsilon^{(t)})/\gamma_{\text{reg}} & (\text{otherwise}), 
\end{array} \right.
\end{align*}
\]

where \( \sigma(\cdot, \cdot) \) is defined by (19).

(ii) It follows that

\[
\sigma(x^+_+, \varepsilon^{(t)}) \geq \bar{\sigma}, \quad t = 0, \ldots, T.
\]

When \( \rho \geq 2 \), we further obtain

\[
\sigma(x^+_+, \varepsilon^{(t)}) \geq \frac{\theta^{-\frac{1}{\rho-1}}}{1 + \sqrt{2\beta}} \cdot \frac{1}{\gamma_{\text{reg}}} \left( \frac{L_f}{L_{\min}} + 1 \right)^{-\frac{1}{\rho-1}} (\varepsilon^{(t)})^{\frac{\rho-2}{\rho-1}} \geq \bar{\sigma}
\]

for each \( t = 0, \ldots, T \).

(iii) For each \( t = 0, \ldots, T + 1 \), we obtain

\[
\sigma^{(t)} \left\{ \begin{array}{ll}
= \sigma^{(0)} & (\sigma^{(0)} \leq \bar{\sigma}), \\
\geq \bar{\sigma}/\gamma_{\text{reg}} & (\text{otherwise}). 
\end{array} \right.
\]

**Proof.** (i) In the case \( \sigma^{(t)} \leq \sigma(x^+_+, \varepsilon^{(t)}) \), Theorem 4.2 (i) implies that the subroutine AdaAPG at the \( t \)-th outer loop must terminate at the first loop \( j = 0 \) so that \( \sigma^{(t+1)} \) is defined by \( \sigma^{(t+1)} = \sigma^{(t)} \). On the other hand, consider the case \( \sigma^{(t)} > \sigma(x^+_+, \varepsilon^{(t)}) \). When the subroutine AdaAPG at the \( t \)-th outer loop terminates at the first loop \( j = 0 \), then it is clear that

\[
\sigma^{(t+1)} = \sigma^{(t)} > \sigma(x^+_+, \varepsilon^{(t)}) \geq \sigma(x^+_+, \varepsilon^{(t)})/\gamma_{\text{reg}}.
\]

In the other case, (20) implies \( \sigma^{(t+1)} \geq \sigma(x^+_+, \varepsilon^{(t)})/\gamma_{\text{reg}} \).

(ii) We may assume \( x^+_+ \notin X^* \) which allows us to apply Lemma 4.6 (iv) (Note that the assertion is clear if \( x^+_+ \in X^* \) since then \( \sigma(x^+_+, \varepsilon^{(t)}) = +\infty \)). In the case \( \rho \geq 2 \), using (34) implies

\[
\sigma(x^+_+, \varepsilon^{(t)}) = \frac{\theta \| g_{M(t)}(x^{(t)}) \|}{(1 + \sqrt{2\beta}) \text{dist}(x^+_+, X^*)} \geq \frac{\theta}{1 + \sqrt{2\beta}} \cdot \frac{1}{\gamma_{\text{reg}}} \left( \frac{L_f}{L_{\min}} + 1 \right)^{-\frac{1}{\rho-1}} \| g_{M(t)}(x^{(t)}) \|^{\frac{\rho-2}{\rho-1}}.
\]

Since \( \varepsilon^{(t)} \equiv \theta \| g_{M(t)}(x^{(t)}) \| \) and \( \| g_{M(t)}(x^{(t)}) \| \geq \varepsilon \) (by the definition of \( T \)), we obtain (37).

If \( \rho \in [1, 2) \), on the other hand, since \( \varphi(x^+_+) \leq \varphi(x^{(0)}) \) by Lemma 4.6 (ii), the inequalities (25) and (35) imply (remark that \( \frac{2-\rho}{\rho} > 0 \)

\[
\text{dist}(x^+_+, X^*) \leq \frac{1}{\gamma_{\text{reg}}} (\varphi(x^+_+) - \varphi^*) \leq \frac{1}{\gamma_{\text{reg}}} (\varphi(x^+_+) - \varphi^*) \leq \frac{1}{\gamma_{\text{reg}}} \varphi(x^+_+) - \varphi^* \leq \frac{1}{\gamma_{\text{reg}}} \varphi(x^+_+) - \varphi^* \leq \frac{1}{\gamma_{\text{reg}}} \varphi(x^+_+) - \varphi^*. \]

\[
\leq \frac{1}{\gamma_{\text{reg}}} \left( \frac{L_f}{L_{\min}} + 1 \right) \| g_{M(t)}(x^{(t)}) \| (\varphi(x^{(t)}) - \varphi^*)^{\frac{2-\rho}{\rho}} \]

\[
\leq \frac{1}{\gamma_{\text{reg}}} \left( \frac{L_f}{L_{\min}} + 1 \right) \| g_{M(t)}(x^{(t)}) \| (\varphi(x^{(0)}) - \varphi^*)^{\frac{2-\rho}{\rho}}. \]

\[23\]
Therefore, we conclude that
\[
\sigma(x_+^{(t)}, \varepsilon^{(t)}) = \frac{\theta \|g_{M(t)}(x^{(t)})\|}{(1 + \sqrt{2}\beta) \text{dist}(x_+^{(t)}, X^*)} \geq \frac{\theta}{1 + \sqrt{2}\beta} \frac{\kappa^2}{\rho} \left( \frac{L_f}{L_{\min}} + 1 \right)^{-1} (\varphi(x^{(0)}) - \varphi^*)^{-\frac{2-\rho}{\rho}} = \bar{\sigma}.
\]
This proves (36).

(iii) In the case \(\sigma(0) \leq \bar{\sigma}, \) (ii) implies \(\sigma(0) \leq \varepsilon(x_+^{(0)}, \varepsilon^{(0)})\). Then, using (i), we have \(\sigma^{(1)} = \sigma^{(0)}\) and also \(\sigma^{(1)} \leq \bar{\sigma}\). Continuing this argument inductively, we conclude that \(\sigma^{(t)} = \sigma^{(t-1)} = \cdots = \sigma^{(0)}\) for all \(t\).

In the case \(\sigma(0) > \bar{\sigma}\), on the other hand, let us show \(\sigma^{(t)} \geq \bar{\sigma}/\gamma_{\text{reg}} (t = 0, \ldots, T + 1)\) by induction. The assertion for \(t = 0\) is clear since \(\sigma(0) \geq \bar{\sigma} \geq \bar{\sigma}/\gamma_{\text{reg}}\). Assume that \(\sigma^{(t)} \geq \bar{\sigma}/\gamma_{\text{reg}}\) holds for some \(t \geq 0\). By (i) and (ii), we have
\[
\sigma^{(t+1)} \geq \min\{\sigma^{(t)}, \varepsilon(x_+^{(t)}, \varepsilon^{(t)})/\gamma_{\text{reg}}\} \geq \min\{\bar{\sigma}/\gamma_{\text{reg}}, \bar{\sigma}/\gamma_{\text{reg}}\} = \bar{\sigma}/\gamma_{\text{reg}}.
\]
This completes the proof of (iii).

In order to provide more accurate complexity analysis, we prove bounds of \(\sigma^{(t)}\) specialized to the case \(\rho > 2\).

**Lemma 4.9.** Assume that the Hölderian error bound condition (25) holds with \(\rho > 2\). Suppose that rAdaAPG terminated with the stopping criterion at the \((T+1)\)-th outer loop for some \(T \geq 0\). If \(\sigma(0) \geq \bar{\sigma}\) holds for \(\bar{\sigma}\) defined by (27), then there exists \(t_0 \in \{0, \ldots, T + 1\}\) such that the following conditions hold, where \(\sigma_*^{(0)} : = \frac{\rho - 2}{\rho - 1} \cdot \kappa^{\frac{1}{\rho - 1}} \left( \frac{L_f}{L_{\min}} + 1 \right)^{-\frac{1}{\rho - 1}} \|g_{M(0)}(x^{(0)})\|^{\frac{\rho - 2}{\rho - 1}}\).

\[
\begin{align*}
(i) & \quad \sigma^{(0)} = \cdots = \sigma^{(t_0)} \tag{38} \\
(ii) & \quad \sigma^{(t+1)} \geq \theta^{-\frac{\rho - 2}{\rho - 1}}(T-t) \bar{\sigma}/\gamma_{\text{reg}}, \quad t = t_0, \ldots, T. \tag{39} \\
(iii) & \quad t_0 \leq 1 + \frac{\rho - 1}{\rho - 2} \log_\frac{\rho}{\rho - 1} \frac{\sigma_*^{(0)}}{\min(\sigma^{(0)}, \sigma_*^{(0)})}. \tag{40} \\
(iv) & \quad \theta^{-\frac{\rho - 2}{\rho - 1}}(T-t_0) \geq \bar{\sigma}/\sigma^{(0)}. \tag{41}
\end{align*}
\]

**Proof.** Define
\[
\sigma_*^{(t)} := \frac{\theta^{-\frac{1}{\rho - 1}}}{1 + \sqrt{2}\beta} \cdot \kappa^{\frac{1}{\rho - 1}} \left( \frac{L_f}{L_{\min}} + 1 \right)^{-\frac{1}{\rho - 1}} (\varepsilon^{(t)})^{\frac{\rho - 2}{\rho - 1}}, \quad t \geq 0.
\]
Then Lemma 4.8 (ii) can be written as
\[
\sigma(x_+^{(t)}, \varepsilon^{(t)}) \geq \sigma_*^{(t)} \geq \bar{\sigma}, \quad t = 0, \ldots, T. \tag{42}
\]
For simplicity, denote
\[
\omega : = \frac{\rho - 2}{\rho - 1} \in (0, 1), \quad c : = \frac{\theta^{-\frac{1}{\rho - 1}}}{1 + \sqrt{2}\beta} \cdot \kappa^{\frac{1}{\rho - 1}} \left( \frac{L_f}{L_{\min}} + 1 \right)^{-\frac{1}{\rho - 1}}
\]
so that we have
\[
\bar{\sigma} = c(\theta \varepsilon)\omega, \quad \sigma_*^{(t)} = c(\varepsilon^{(t)})\omega, \quad t \geq 0.
\]
Note that \( \{ \sigma_s^{(t)} \} \) is non-increasing; in fact, the relation \( \varepsilon^{(t+1)} \leq \theta \varepsilon^{(t)} \) implies
\[
\sigma_s^{(t+1)} = c(\varepsilon^{(t+1)})^\omega \leq c\theta^\omega(\varepsilon^{(t)})^\omega = \theta^\omega \sigma_s^{(t)} \leq \sigma_s^{(t)}.
\] (43)

Let \( t_0 \) be the smallest integer in \( \{0, \ldots, T+1\} \) such that \( \sigma^{(0)} \geq \sigma_s^{(t_0)} \). Remark that, by the definition of \( T \), we have \( \varepsilon^{(T+1)} = \theta \|g_{M(T+1)}(x^{(T+1)})\|_s \leq \theta \varepsilon \). This implies that
\[
\sigma^{(0)} \geq \bar{\sigma} = c(\theta \varepsilon)^\omega \geq c(\varepsilon^{(T+1)})^\omega = \sigma_s^{(T+1)}.
\]

Therefore, \( t_0 \) is well-defined.

(i) By the definition of \( t_0 \) and (42), we have
\[
\sigma^{(0)} < \sigma_s^{(t)} \leq \sigma(x_+^{(t)}, \varepsilon^{(t)}), \quad 0 \leq t < t_0.
\]

Therefore, by induction, we obtain \( \sigma^{(0)} = \sigma^{(1)} = \cdots = \sigma^{(t_0)} \) due to Lemma 4.8 (i).

(ii) Let us show \( \sigma^{(t+1)} \geq \sigma_s^{(t)} / \gamma_{\text{reg}} \) for \( t = t_0, \ldots, T+1 \) by induction. To prove this, we verify \( \sigma^{(t)} \geq \sigma_s^{(t)} / \gamma_{\text{reg}} \) for \( t = t_0, \ldots, T \) by induction. Note that \( \sigma^{(t_0)} = \sigma^{(0)} \geq \sigma_s^{(t_0)} > \sigma_s^{(t_0)} / \gamma_{\text{reg}} \) holds by (i) and the definition of \( t_0 \). Now under the hypothesis \( \sigma^{(t)} \geq \sigma_s^{(t)} / \gamma_{\text{reg}} \) for \( t \) with \( t_0 \leq t \leq T \), Lemma 4.8 (i) and (42) imply
\[
\sigma^{(t+1)} \geq \min\{\sigma^{(t)}, \sigma(x_+^{(t)}, \varepsilon^{(t)}) / \gamma_{\text{reg}}\} \geq \min\{\sigma_s^{(t)} / \gamma_{\text{reg}}, \sigma_s^{(t)} / \gamma_{\text{reg}}\} = \sigma_s^{(t)} / \gamma_{\text{reg}} \geq \sigma_s^{(t+1)} / \gamma_{\text{reg}}.
\]

Therefore, this completes the induction; in addition, the above inequality proves the desired inequality \( \sigma^{(t+1)} \geq \sigma_s^{(t)} / \gamma_{\text{reg}} \) \( (t_0 \leq t \leq T) \). This yields (ii) combined with (42) and (43):
\[
\sigma^{(t+1)} \geq \sigma_s^{(t)} / \gamma_{\text{reg}} \geq \theta^{-\omega(T-t)} \sigma_s^{(T)} / \gamma_{\text{reg}} \geq \theta^{-\omega(T-t)} \bar{\sigma} / \gamma_{\text{reg}}, \quad t = t_0, \ldots, T.
\]

(iii) If \( t_0 = 0 \), then (iii) is trivial since \( \sigma^{(0)} \geq \sigma_s^{(0)} = \sigma_s^{(t_0)} \). If \( t_0 > 0 \), then the definition of \( t_0 \) and using (43) imply
\[
\sigma^{(0)} < \sigma_s^{(t_0-1)} \leq \theta^{-\omega(t_0-1)} \sigma_s^{(t_0)},
\]
which yields \( t_0 \leq 1 + \log_1 / \theta / \frac{\sigma_s^{(0)}}{\gamma_{\text{reg}}} \).

(iv) By (42), (43), and the definition of \( t_0 \), remark that
\[
\bar{\sigma} \leq \sigma_s^{(T)} \leq \theta^{-\omega(T-t_0)} \sigma_s^{(t_0)} \leq \theta^{-\omega(T-t_0)} \sigma^{(0)}.
\]
Hence, \( \theta^{-\omega(T-t_0)} \geq \bar{\sigma} / \sigma^{(0)} \) holds. \( \Box \)

Finally, we present the proofs of Theorem 4.4 and Corollary 4.5.

**Proof of Theorem 4.4.** We may assume that \( \|g_{M(0)}(x^{(0)})\| > \varepsilon \) since \( N = 0 \) on the other case. Suppose that \texttt{rAdaAPG} terminated with the stopping criterion at the \( (T+1) \)-th outer loop for some \( T \geq 0 \). Denote by \( N^{(t)} \) the number of the executions of \texttt{APGIter} at the \( t \)-th outer loop so that \( N = \sum_{t=0}^{T} N^{(t)} \).

Let \( \bar{\sigma} \) be defined by (27).

By the definition of \( T \), we have
\[
\|g_{M(t)}(x^{(t)})\| > \varepsilon, \quad t = 0, \ldots, T.
\] (44)

Moreover, by the definition of \( \sigma_s \) in (28), using Lemma 4.8 (iii) implies
\[
\sigma^{(t)} \geq \sigma_s, \quad t = 0, \ldots, T+1.
\]
Therefore, applying Lemma 4.7 with \( T_s = T \), we obtain the assertion

\[
N \leq N(\varepsilon, \sigma_*, C) \quad \text{with} \quad C = \sqrt{\frac{1}{\sigma_*}} \left( 1 + \log_{1/\theta} \frac{\|g_{M(0)}(x^{(0)})\|}{\varepsilon} \right). \tag{45}
\]

For the case \( \rho = 2 \), (45) proves the assertion (i). We discuss the other cases to improve (45).

(ii) Case \( \rho > 2 \). If \( \sigma(0) < \bar{\sigma} \), then \( \sigma_* \) is defined as \( \sigma_* = \sigma(0) \). Therefore, the latter bound of (ii) is obtained by (45).

Now consider the case \( \sigma(0) \geq \bar{\sigma} \). Then, there exists \( t_0 \in \{0, \ldots, T + 1\} \) satisfying the conditions in Lemma 4.9. By (41), remark that

\[
\sum_{t=t_0}^{T} \sqrt{\theta_{\rho-1}^{\alpha-2}(T-t)} = \sum_{t=0}^{T-t_0} \sqrt{\theta_{\rho-1}^{\alpha-2}} = 1 - \sqrt{\frac{\theta_{\rho-1}^{\alpha-2}}{1 - \sqrt{\theta_{\rho-1}^{\alpha-2}}} \frac{\sigma}{\sigma(0)}} \leq 1 - \sqrt{\frac{\theta_{\rho-1}^{\alpha-2}}{1 - \sqrt{\theta_{\rho-1}^{\alpha-2}}} \frac{\sigma}{\sigma(0)}}. \tag{46}
\]

Therefore, we conclude that

\[
\sum_{t=0}^{T} \frac{1}{\sigma(t+1)} = \sum_{t=0}^{t_0-1} \frac{1}{\sigma(t+1)} + \sum_{t=t_0}^{T} \frac{1}{\sigma(t+1)} \leq t_0 \frac{1}{\sigma(0)} + \sqrt{\gamma_{\text{reg}} \sum_{t=t_0}^{T} \theta_{\rho-1}^{\alpha-2}(T-t)} \leq \frac{1}{\sigma(0)} \left( 1 + \frac{\rho - 1}{\rho - 2} \log_{1/\theta} \frac{\sigma(0)}{\min(\sigma_*, \sigma(0))} \right) + \sqrt{\gamma_{\text{reg}}} \left( \sqrt{\frac{1}{\sigma}} - \sqrt{\frac{\theta_{\rho-1}^{\alpha-2}}{1 - \sqrt{\theta_{\rho-1}^{\alpha-2}}} \frac{1}{\sigma(0)}} \right) \leq \frac{1}{\sigma_*(t)} := \frac{1}{\sigma(t+1)}
\]

With this definition of \( C \), Lemma 4.7 gives \( N \leq N(\varepsilon, \sigma_*, C) \).

(iii) Case \( \rho \in (1, 2) \). If \( \varepsilon \geq \varepsilon_* \), then (45) gives our assertion because the second term of (29) vanishes. Suppose, on the other hand, that \( \varepsilon < \varepsilon_* \). Denote

\[
\xi_t := \frac{1}{\|g_{M(t)}(x^{(t)})\|},
\]

and let \( T_s \geq 0 \) be the smallest integer such that \( \xi_{T_s} \leq \varepsilon_* \). Then, since \( \xi_{T_s-1} > \varepsilon_* \) holds, Lemma 4.7 shows that

\[
\sum_{t=0}^{T_s-1} N^{(t)} \leq N(\varepsilon_*, \sigma_*, C) \quad \text{with} \quad C = \sqrt{\frac{1}{\sigma_*}} \left( 1 + \log_{1/\theta} \frac{\|g_{M(0)}(x^{(0)})\|}{\varepsilon} \right). \tag{45}
\]

Note that, under the convention \( \sum_{t=0}^{T} N^{(t)} = 0 \), this inequality also holds if \( T_s = 0 \) since then \( \xi_0 \leq \varepsilon_* \) and \( N(\varepsilon_*, \sigma_*, C) = 0 \).

It remains to observe \( \sum_{t=t_s}^{T_s} N^{(t)} \). Take \( t \in \{T_s, \ldots, T\} \). We shall prove \( N^{(t)} = 1 \). In the \( t \)-th outer loop, consider the first iteration of the subroutine \( \text{AdaAPG}(x_+, L, \sigma(t), \varepsilon(t)) \), which executes

\[
\{x_1, \psi_1, M_0, L_1, A_1\} \leftarrow \text{APGIter}_{\sigma(t)}(x^{(t)}_+, \psi_0, L^{(t)}, A_0),
\]

26
where \( \psi_0(x) = \frac{1}{2} \| x - x_+^{(t)} \|^2 \) and \( A_0 = 0 \). Then Proposition 3.6 (v) implies
\[
\| g_{M_0}(x_1) \| \leq \left( 2 \sqrt{\frac{M_0 + \sigma^{(t)}}{A_1}} + \sigma^{(t)} \right) \text{dist}(x_+^{(t)}, X^*).
\]

Moreover, according to the equation at Line 5 in Algorithm 1, \( A_1 \) can be calculated as \( A_1 = 2/M_0 \). Now remark that, using \( M_0 \leq \gamma_{\text{inc}} L_f \) (Proposition 3.6 (i)), we have
\[
2 \sqrt{\frac{M_0 + \sigma^{(t)}}{A_1}} + \sigma^{(t)} = 2 \sqrt{\frac{M_0(M_0 + \sigma^{(t)})}{2}} + \sigma^{(t)} \leq 2 \sqrt{\frac{(M_0 + \sigma^{(t)})^2}{2}} + (M_0 + \sigma^{(t)}) = (1 + \sqrt{2})(M_0 + \sigma^{(t)}) \leq (1 + \sqrt{2})(\gamma_{\text{inc}} L_f + \sigma^{(t)}).
\]

Combining them and using (34)\(^4\), we conclude that
\[
\| g_{M_0}(x_1) \| \leq (1 + \sqrt{2})(\gamma_{\text{inc}} L_f + \sigma^{(t)}) \text{dist}(x_+^{(t)}, X^*),
\]
\[
\leq (1 + \sqrt{2})(\gamma_{\text{inc}} L_f + \sigma^{(t)}) \left( \frac{1}{\kappa} \right) \frac{1}{\rho} \frac{1}{\kappa} \left( \frac{L_f}{L_{\text{min}}} + 1 \right) \frac{1}{\kappa} \frac{1}{\rho} \xi_t \frac{1}{\rho - 1},
\]
\[
= \theta \varepsilon_t \frac{\rho - 2}{\rho - 1} \xi_t \frac{1}{\rho - 1}, \quad t = T_v, \ldots, T.
\]

Since \( \frac{1}{\rho - 1} > 1 \), it reduces \( \xi_t \) superlinearly. In particular, solving this recurrence implies
\[
\log \frac{\varepsilon_t}{\theta \varepsilon_t \frac{\rho - 2}{\rho - 1} \xi_T} \geq \left( \frac{1}{\rho - 1} \right)^{T - T_v} \log \frac{\varepsilon_t}{\theta \varepsilon_t \frac{\rho - 2}{\rho - 1} \xi_T}. \]

Since \( \xi_T > \varepsilon \) and \( \xi_{T_v} \leq \varepsilon \), we obtain
\[
\sum_{t = T_v}^{T} N(t) = T - T_v + 1 \leq 1 + \left( \log \frac{1}{\rho - 1} \right)^{-1} \left( \log \log \frac{\varepsilon_T}{\theta \varepsilon_T \frac{\rho - 2}{\rho - 1} \xi_T} - \log \log \frac{1}{\theta \varepsilon_T \frac{\rho - 2}{\rho - 1} \xi_T} \right).
\]

Consequently, \( N \) is bounded as follows.
\[
N = \sum_{t = 0}^{T_v - 1} N(t) + \sum_{t = T_v}^{T} N(t) \leq N(\varepsilon, \sigma, C) + 1 + \left( \log \frac{1}{\rho - 1} \right)^{-1} \left( \log \log \frac{\varepsilon_T}{\theta \varepsilon_T \frac{\rho - 2}{\rho - 1} \xi_T} - \log \log \frac{1}{\theta \varepsilon_T \frac{\rho - 2}{\rho - 1} \xi_T} \right).
\]

(iv) Case \( \rho = 1 \). We have \( \sigma^{(t)} \geq \sigma \) for each \( t = 0, \ldots, T + 1 \), by Lemma 4.8 (iii). Moreover, Lemma 4.6 (vi) shows that, if \( x_+^{(t)} \notin X^* \), then we have
\[
1 \leq \frac{1}{\kappa} \left( \frac{L_f}{L_{\text{min}}} + 1 \right) \| g_{M(t)}(x(t)) \|, \quad \text{i.e.,} \quad \| g_{M(t)}(x(t)) \| \geq \varepsilon_* := \kappa \left( \frac{L_f}{L_{\text{min}}} + 1 \right)^{-1}.
\]
\(^4\)Although (34) is asserted in the case \( x_+^{(t)} \notin X^* \), it trivially holds if \( x_+^{(t)} \in X^* \) unless \( \rho = 1 \).
In other words, the condition \( \| g_{M(t)}(x(t)) \| < \varepsilon_s \) must imply \( x_+^{(t)} \in X^* \) which also yields \( N(t) = 1 \) and \( x_+^{(t+1)} = x_+^{(t)} \in X^* \) by Proposition 3.6 (v) (then the algorithm terminates at the \((t+1)\)-th outer loop). Therefore, we have
\[
\| g_{M(t)}(x(t)) \| \geq \varepsilon_s, \quad 0 \leq t \leq T - 1.
\] (48)

Now we consider two cases. If \( \| g_{M(T)}(x(T)) \| \geq \varepsilon_s \) holds, then combining with (44) yields \( \| g_{M(T)}(x(T)) \| \geq \max(\varepsilon, \varepsilon_s) \), from which Lemma 4.7 with \( T_s = T \) concludes
\[
N \leq N(\max(\varepsilon, \varepsilon_s), \sigma_s, C) \quad \text{with} \quad C = \sqrt{\frac{T}{\sigma_s}} \left( 1 + \log_{1/\theta} \frac{\| g_{M(0)}(x(0)) \|}{\max(\varepsilon, \varepsilon_s)} \right).
\]

On the other case \( \| g_{M(T)}(x(T)) \| < \varepsilon_s \), we have \( N(T) = 1 \). Since (44) and (48) implies \( \| g_{M(T-1)}(x(T-1)) \| \geq \max(\varepsilon, \varepsilon_s) \), Lemma 4.7 with \( T_s = T - 1 \) shows \( \sum_{t=0}^{T-1} N(t) \leq N(\max(\varepsilon, \varepsilon_s), \sigma_s, C) \). Hence,
\[
N = N(T) + \sum_{t=0}^{T-1} N(t) \leq 1 + N(\max(\varepsilon, \varepsilon_s), \sigma_s, C).
\]

This proves the desired bound on \( N \). To show the latter assertion of (iv), suppose \( \varepsilon < \varepsilon_s \). Then the output \( \{ x(T+1), M(T+1), x_+^{(T+1)} \} \) satisfies \( \| g_{M(T+1)}(x(T+1)) \| \leq \varepsilon < \varepsilon_s \). Therefore, \( x_+^{(T+1)} \) must be optimal.

The proof of Theorem 4.4 is completed.

**Proof of Corollary 4.5.** The function \( N(\cdot, \cdot, \cdot) \) defined in (26) has the following expression.
\[
N(\varepsilon, \sigma_0, C) = O \left( \log \frac{L_f + \sigma_s}{\sigma_s} \left[ \log \frac{\| g_0 \|}{\varepsilon} + \log \frac{\sigma_0}{\sigma_s} + \sqrt{\frac{L_f}{\sigma_s} + C \sqrt{L_f}} \right] \right).
\]

By the choice (31) of \( \sigma_0(0) \), we can apply Corollary 4.3 and then the bound (23) becomes
\[
\varepsilon(x_+^{(0)}, \varepsilon(0)) \leq \sigma(0) \leq \frac{2\gamma \min L_f}{1 + \sqrt{2\beta}}.
\] (49)

Then, we have \( \sigma(0) \geq \bar{\sigma} \) since \( \varepsilon(x_+^{(0)}, \varepsilon(0)) \geq \bar{\sigma} \) holds by Lemma 4.8 (ii). Therefore, \( \sigma_s \) in (28) becomes \( \sigma_s = \Theta(\bar{\sigma}) \), which also implies \( \sigma_* = O(\sigma(0)) = O(L_f) \) combined with (49). Applying the bounds \( \sigma(0) = O(L_f) \), \( \sigma_* = O(L_f) \), and \( \sigma_s = \Omega(\bar{\sigma}) \), we obtain
\[
N(\varepsilon, \sigma_0, C) = O \left( \log \frac{L_f}{\sigma} \left[ \log \frac{\| g_0 \|}{\varepsilon} + \sqrt{\frac{L_f}{\sigma} + C \sqrt{L_f}} \right] \right).
\] (50)

If \( \rho = 2 \), Theorem 4.4 (i) implies \( N(\varepsilon, \sigma_0, C) \) with \( C = O \left( \sqrt{\frac{1}{\sigma}} \log \frac{\| g_0 \|}{\varepsilon} \right) \). In particular, (50) yields
\[
N(\varepsilon, \sigma_0, C) = O \left( \sqrt{\frac{L_f}{\sigma}} \log \frac{L_f}{\sigma} \log \frac{\| g_0 \|}{\varepsilon} \right).
\] (51)

Since \( \bar{\sigma} = \Theta(\kappa) \) by (27), we conclude the bound (32) in the case \( \rho = 2 \).

In the case \( \rho = 1 \), using Theorem 4.4 (iv), the same argument as the case \( \rho = 2 \) can be applied to obtain (51) replacing \( \varepsilon \) by \( \max(\varepsilon, \varepsilon_s) \), where \( \varepsilon_s = \kappa(L_f/L_\min + 1)^{-1} = O(\kappa) \). Since \( \bar{\sigma} = \Omega(\kappa^2/\Delta_0) \) by (27), we obtain the bound (32) in the case \( \rho = 1 \).
In the case \( \rho \in (1, 2) \), we apply Theorem 4.4 (iii) and the argument is similar to the previous cases. Therefore, the bound (32) in this case can be obtained based on the estimate (51) replacing \( \varepsilon \) by \( \max(\varepsilon, \varepsilon_*) \) and applying \( \bar{\sigma} = \Omega(\kappa^{\frac{1}{\rho}} L f^{-\frac{1}{\rho}}) \).

Finally, consider the case \( \rho > 2 \). By Lemma 4.8 (ii) and (49), remark that \( \sigma(0) \geq \sigma_* \geq \bar{\sigma} \) holds. Then, Theorem 4.4 (ii) implies \( N \leq N(\varepsilon, \sigma_*, C) \) with \( C = O(\sqrt{\frac{\sigma(0)}{\varepsilon}} + \sqrt{\frac{1}{\sigma_*}}) = O\left(\sqrt{\frac{1}{\sigma_*}}\right) \). Therefore, (50) applying \( \bar{\sigma} = \Omega(\kappa^{\frac{1}{\rho}} \varepsilon^{-\frac{1}{\rho}}) \) concludes the bound (32) in the case \( \rho > 2 \).

5 Concluding remarks

In this paper, we proposed two adaptive proximal gradient methods, Algorithms 3 and 4. The former algorithm is nearly optimal for the class of problems where \( f \) is \( L \)-smooth. If we additionally assume the Hölderian error bound condition, the latter algorithm ensures the near optimality. It is unclear whether the latter algorithm also provides the near optimality without the Hölderian error bound.

A remarkable fact of the proposed method (Algorithm 4) is the near optimality with respect to the gradient norm under the Hölderian error bound condition, thanks to the lower complexity bound (13). Remark that the optimal complexity of the first-order methods for \( L \)-smooth convex functions under the gradient norm is unknown [16], namely, it is open whether we can reduce the logarithmic factor of the complexity bound (24). Similarly, it is an important question whether we can improve the complexity (32) to attain the lower bounds (13).

The essential idea of this work is the adaptive determination of the regularization parameter \( \sigma \) used to define the regularization \( \varphi_{\sigma}(x) \). As proved in Theorem 4.2, our method (Algorithm 3) adapts the unknown desired regularization parameter \( \sigma(x_0, \varepsilon) = \varepsilon (1 + \sqrt{2\beta}) \text{dist}(x_0, X^*) \). This feature is also critical for the development of the restart scheme (Algorithm 4) to adapt the Hölderian error bound condition. Basically, this adaption is obtained thanks to the connection of \( \sigma(x_0, \varepsilon) \) (in other words, \( \text{dist}(x_0, X^*) \)) with the “problem structure” denoted as \( \bar{\sigma} \) (cf. Lemma 4.8 (ii)). This might suggest the possibility of dealing with this adaptive regularization approach under other kinds of problem structures.
