GENERAL RELATIVISTIC EFFECTS ON
THE INDUCED ELECTRIC FIELD
EXTERIOR TO PULSARS

Abstract

The importance of general relativity to the induced electric field exterior to pulsars has been investigated by assuming aligned vacuum and non-vacuum magnetosphere models. For this purpose the stationary and axisymmetric vector potential in Schwarzschild geometry has been considered and the corresponding expressions for the induced electric field due to the rotation of the magnetic dipole have been derived for both vacuum and non-vacuum conditions. Due to the change in the magnetic dipole field in curved spacetime the induced electric field also changes its magnitude and direction and increases significantly near the surface of the star. As a consequence the surface charge density, the acceleration of charged particles in vacuum magnetospheres and the space charge density in non-vacuum magnetosphere greatly increase near the surface of the star. The results provide the most general feature of the important role played by gravitation and could have several potentially important implications for the production of high-energy radiation from pulsars.

Subject headings: electromagnetism : theory – pulsars : general – relativity – stars : neutron
1. INTRODUCTION

The realization that pulsars are most likely to be neutron stars surrounded by a dense magnetosphere (Gold 1968; Pacini 1968) and the pioneering work by Goldreich and Julian (1969) have provided the basic physical model on which virtually all particular models have been based. At present two general types of models are being considered in-order to understand the phenomenon of high energy radiation from pulsars viz., the polar cap model (Arons 1983) and the outer gap model (Cheng, Ho & Ruderman 1986). Goldreich and Julian first realized that in spite of the intense surface gravity, the neutron star must possess a dense magnetosphere. Unfortunately the actual role played by gravitation in this aspect has not been investigated so far in detail.

General relativistic effects near pulsars have been explored only in the context of emission models for X-ray pulsars and gamma-ray burst. The effect of light bending in X-ray burst and X-ray pulsars was studied by Meszaros and Riffert (1988), Riffert, Meszaros & Bagoly (1989). Recently Gonthier and Harding (1994) have examined the importance of general relativistic corrections to the production of gamma rays near the surface of neutron stars.

It is well-known that the induced electric field due to the rapid rotation of the magnetic dipole of a neutron star plays the main role in determining the characteristic of the pulsar magnetosphere since this quantity determines the number density of charged particles torn off from the surface of the star, the acceleration of charged particles and hence the production of electromagnetic radiation, etc. Since the magnetic field in curved spacetime differs in both magnitude and direction from that in flat spacetime, the induced electric field is also different in curved spacetime. Therefore it is very important to include general relativity in any discussion of pulsar magnetosphere.

In this paper the importance of general relativistic corrections to the induced electric field external to a neutron star has been investigated quantitatively by considering the simplest aligned vacuum and non-vacuum magnetosphere models.

The paper is organized in the following way: In section 2 the Schwarzschild metric and the corresponding orthonormal tetrad components alongwith the transformation rules are given. In section 3 we discuss the dipole magnetic field in Schwarzschild spacetime which has been used to determine the induced electric field in section 4. In section 4 a detail quantitative
discussion on the effects of spacetime curvature to the various important quantities governed by the electric field has been presented. For simplicity we have assumed the vector potential to be stationary and axisymmetric. Finally we conclude the discussions in section 5.

2. THE SPACETIME METRIC

Since we are interested on the electromagnetic field exterior to the neutron star, we consider the Schwarzschild metric as it provides a simple description of the spacetime geometry exterior to neutron stars.

The metric is given by:

$$ds^2 = (1 - 2m/r)c^2 dt^2 - (1 - 2m/r)^{-1} dr^2 - r^2 d\theta^2 - r^2 \sin^2 \theta d\phi^2$$  \hspace{1cm} (1)

where \( m = MG/c^2 \), M being the total mass of the star.

The non-zero components of the orthonormal tetrad \( \lambda^i_{(\alpha)} \) of the local Lorentz frame for Schwarzschild geometry are given by

$$\lambda^t_{(t)} = (1 - 2m/r)^{-1/2}, \lambda^r_{(r)} = (1 - 2m/r)^{1/2}, \lambda^\theta_{(\theta)} = \frac{1}{r}, \lambda^\phi_{(\phi)} = \frac{1}{r \sin \theta}. \hspace{1cm} (2)$$

If \( F_{(\alpha\beta)} \) are the components of the electromagnetic field tensor in local Lorentz frame, then the components of the electromagnetic field tensor \( F_{ij} \) defined in the curved spacetime through

$$F_{(\alpha\beta)} = \lambda^i_{(\alpha)} \lambda^j_{(\beta)} F_{ij} \hspace{1cm} (2)$$

3. THE DIPOLE MAGNETIC FIELD IN CURVED SPACETIME

Since the magnetic field of a neutron star is generally approximated to be that of a pure magnetic dipole, in flat spacetime we can write the components of the magnetic field (in polar coordinates) as

$$B = \frac{2 \mu}{r^3} (\cos \theta, \frac{1}{2} \sin \theta, 0) \hspace{1cm} (3)$$

where \( \mu \) is the magnetic dipole moment.

The magnetic dipole has to be modified in curved spacetime. In Schwarzschild spacetime the electromagnetic potential \( A_i \) is given by (Pettersen 1974; Wasserman & Shapiro 1983)

$$A_i = (0, 0, A_\phi, 0) \hspace{1cm} (4)$$
with
\[ A_\phi = -\frac{3\mu \sin^2 \theta}{8m^3} [r^2 \ln(1 - 2m/r) + 2mr + 2m^2] \] (4)

Using the definition \( F_{ij} = (A_{j,i} - A_{i,j}) \) we get the components of the magnetic field in Schwarzschild geometry as
\[ F_{r\phi} = -\frac{3\mu \sin^2 \theta}{4m^2} \left[ \frac{r}{m} \ln(1 - 2m/r) + (1 - 2m/r)^{-1} + 1 \right] \] (5)
\[ F_{\theta\phi} = -\frac{3\mu r^2}{4m^3} \sin \theta \cos \theta \left[ \ln(1 - 2m/r) + \frac{2m}{r}(1 + m/r) \right] \] (6)

Therefore using equation (2) we get
\[ B_r(Sch) = -\frac{3\mu \cos \theta}{4m^3} \left[ \ln(1 - 2m/r) + \frac{2m}{r}(1 + m/r) \right] \] (7)
\[ B_\theta(Sch) = \frac{3\mu \sin \theta}{4m^2r} \left[ \frac{r}{m} \ln(1 - 2m/r) + (1 - 2m/r)^{-1} + 1 \right] (1 - 2m/r)^{1/2} \] (8)

It should be mentioned that the above expressions are specialized to the lowest order expansion in terms of spherical harmonics. Nevertheless they are valid in the context of neutron stars since the magnetic field is not so strong relative to the gravitational field such that the spacetime geometry could be affected significantly by the magnetic field.

4. THE INDUCED ELECTRIC FIELD IN CURVED SPACETIME

In order to investigate the effect of curved spacetime on the electric field exterior to a rotating neutron star, we consider two simplest models, viz., (1) the aligned vacuum rotator and (2) the aligned non-vacuum rotator. Since the effect of curvature would be the same, the results will provide the most general feature for any magnatospheric model which assumes stationary \( (\frac{\partial}{\partial t} = 0) \) and axisymmetric \( (\frac{\partial}{\partial \phi} = 0) \) behavior of the vector potential. In the present study we have ignored any effects due to magnetosphere plasma. Also we have neglected the dragging of inertial frame due to rotation which is insignificant at the exterior of even millisecond pulsars.

4.1. The Aligned Vacuum Rotator

Since the derivations are nothing but a generalization of Goldreich - Julian solution, we briefly discuss it before going to derive the electromagnetic field in curved spacetime although it can be found in any text book on Pulsars e.g., Shapiro and Teukolsky (1983).
First of all it is considered that a rotating neutron star has an aligned dipole external magnetic field given by equation (3). The stellar material is assumed to be an excellent conductor so that just inside the star an electric field will be present which satisfies

\[ \mathbf{E}^{\text{int}} + \frac{\mathbf{\omega} \times \mathbf{r}}{c} \times \mathbf{B}^{\text{int}} = 0 \]  

where \( \mathbf{\omega} \) is the angular velocity vector of the star.

Here and afterwards the superscript ‘int’ is to be understood to represent the quantities just inside the star and not far below the surface where the above condition may not be valid.

Assuming there are no surface currents, both the normal and the tangential components of \( \mathbf{B} \) are continuous across the stellar surface. Thus just inside the surface the magnetic field can be written by taking \( r = R \) in equation (3) where \( R \) is the radius of the star. Then equation (9) gives for \( \mathbf{E} \) just inside the surface

\[ \mathbf{E}^{\text{int}} = \frac{2\mu\omega}{cR^2}(\frac{1}{2} \sin^2 \theta, -\sin \theta \cos \theta, 0) \]  

The tangential component of \( \mathbf{E} \) is continuous across the surface, so just outside the star equation (10) implies

\[ E_\theta^{\text{ext}} = -\frac{\partial}{\partial \theta}(\frac{\mu\omega \sin^2 \theta}{cR^2}) = \frac{\partial}{\partial \theta}[\frac{2\mu\omega}{3cR^2} P_2(\cos \theta)] \]  

where \( P_2 \) is the Legendre polynomial of second degree.

In the present case since the exterior is assumed to be vacuum, so

\[ \mathbf{E}^{\text{ext}} = -\nabla \phi \]

where

\[ \nabla^2 \phi = 0 \]

In order to satisfy the boundary condition given by equation (11) at \( r = R \), the solution of equation (12) must be

\[ \phi = -\frac{2\mu\omega R^2}{3cR^3} P_2(\cos \theta) \]
and hence

\[ \mathbf{E}_{\text{ext}}^{\text{ext}} = -\frac{\mu \omega R^2}{cr^4} [(3 \cos^2 \theta - 1), 2 \sin \theta \cos \theta, 0] \tag{13} \]

Now we will derive the electric components exterior to a rotating neutron star for Schwarzschild background geometry with the basic assumptions taken in the above discussions unaltered.

Equation (9) can be written in its covariant form as

\[ F^\beta_\delta u^\delta = 0 \tag{14} \]

where \( u^\delta \) are the components of the four velocity vector.

From equation (14) we obtain

\[ F_{rt} = F_{\phi r} \frac{u^\phi}{u^t} \tag{15} \]

\[ F_{\theta t} = F_{\phi \theta} \frac{u^\phi}{u^t} \tag{16} \]

(Note that \( u = (u^t, 0, 0, u^\phi) \) for the present case.)

Using equations (5) and (6) and noting that in Schwarzschild geometry

\[ E_r = F_{(rt)} = F_{rt} \]

\[ E_\theta = F_{(\theta t)} = F_{\theta t}/[r(1 - 2m/r)^{1/2}] \]

and taking

\[ \frac{u^\phi}{u^t} = \frac{\omega}{c} \]

we obtain the induced electric field components just inside the surface \((r \simeq R)\) as

\[ E_r^{\text{int}} = \frac{3 \mu \omega \sin^2 \theta}{4m^2} [(1 - 2m/r)^{-1} + \frac{r}{m} \ln(1 - 2m/r) + 1] \tag{17} \]

\[ E_\theta^{\text{int}} = \frac{3 \mu \omega \cos \theta \sin \theta}{4cm^3} [\ln(1 - 2m/r) + \frac{2m}{r}(1 + \frac{m}{r})](1 - \frac{2m}{r})^{-1/2} \tag{18} \]
If $f(r)$ and $g(r)$ are two arbitrary functions which solely determine the spacetime curvature effect then in curved spacetime we can write

\[ E_r^{\text{int}}(\text{curved}) = \frac{\mu \omega}{cr^2} \sin^2 \theta f(r) \quad (19) \]

\[ E_\theta^{\text{int}}(\text{curved}) = -\frac{2\mu \omega}{cr^2} \sin \theta \cos \theta g(r) \quad (20) \]

Comparing equations (19) and (20) with equations (17) and (18) we obtain

\[ f(r) = \frac{3r^2}{4m^2}[(1 - 2m/r)^{-1} + \frac{r}{m} \ln(1 - 2m/r) + 1] \quad (21) \]

\[ g(r) = -\frac{3r^3}{8m^3} \ln(1 - 2m/r) + \frac{2m}{r} (1 + \frac{m}{r})(1 - \frac{2m}{r})^{-1/2} \quad (22) \]

In the above derivations we have assumed that the metric can well describe the spacetime curvature just below the surface $(r \simeq R)$ of the star, i.e., the curvature effect just below the surface is the same as that at the surface to the star.

In flat spacetime the components of the exterior electric field is given by equation (13). Therefore in Schwarzschild geometry the components of the exterior electric field can be written as

\[ E_r^{\text{ext}}(\text{Sch}) = -\frac{\mu \omega R^2}{cr^4} (3 \cos^2 \theta - 1) f(r) \]

\[ = -\frac{3\mu \omega R^2}{4cm^2r^2} (3 \cos^2 \theta - 1) [(1 - 2m/r)^{-1} + \frac{r}{m} \ln(1 - 2m/r) + 1] \quad (23) \]

\[ E_\theta^{\text{ext}}(\text{Sch}) = -\frac{2\mu \omega R^2}{cr^4} \sin \theta \cos \theta g(r) \]

\[ = \frac{3\mu \omega R^2 \cos \theta \sin \theta}{4cm^3r} [\ln(1 - 2m/r) + \frac{2m}{r} (1 + \frac{m}{r})(1 - \frac{2m}{r})^{-1/2} \quad (24) \]

Clearly $E^{\text{ext}}(\text{curved}) \to E^{\text{ext}}(\text{flat})$ as $r \to \infty$ as desired.

Taking as examples, the Crab pulsar with mass $M$ equal to 1.4 solar mass, radius $R$ equal to $10^6 cm$, period $P$ equal to 33 ms and the magnetic dipole moment $\mu$ equal to $2 \times 10^{30} G cm^3$ we show in Figure 1 the $r$ component of the quadrupole electric field at an angle $\theta = 0^\circ$ to the axis of rotation as a function of distance from the stellar surface for flat and curved spacetimes. It is found that a significant increase in the electric field intensity near the surface is caused due to the inclusion of general relativistic effect.
Now we have the functional form for the dipole magnetic field and the quadrapole electric field in flat spacetime as well as in Schwarzschild spacetime. We would like to see how the field lines differ in two different geometries. The field lines represent a constant magnetic and electric flux $b(\theta)$ and $e(\theta)$ respectively and can be found by rotating a given field line about the z-axis in a spherical co-ordinate system with the magnetic dipole aligned with the z-axis. The fluxes from $\theta = 0$ to $\theta$ are given by

$$b(\theta) = \int_0^\theta B_r \cdot da = \int_0^\theta B_r r^2 d\Omega$$ (25)

$$e(\theta) = \int_0^\theta E_r \cdot da = \int_0^\theta E_r r^2 d\Omega$$ (26)

The magnetic field lines in flat spacetime and in curved spacetime have been presented by Gonthier and Harding (1994).

For an induced quadrapole electric field in flat spacetime the field lines are

$$e(\theta) = -\frac{2\pi \mu \omega R^2}{cr^2} \sin^2 \theta \cos \theta = constant$$ (27)

In curved spacetime the field lines are given by

$$e(\theta) = -\frac{3\pi \mu \omega R^2}{2m^2c} \sin^2 \theta \cos \theta[(1 - 2m/r)^{-1} + \frac{r}{m} \ln(1 - 2m/r) + 1]$$

$$= constant$$ (28)

Taking the Crab pulsar as an example with a period of 33 ms we show in Figure 2a the quadrapole electric field lines in the z-x plane out to 40 stellar radii, beyond which the effect of curvature becomes insignificant. Figure 2b shows a closer view of the same field lines.

Since the normal component of the electric field is discontinuous for the case of aligned vacuum rotator, the corresponding surface charge density can be written in flat spacetime as

$$\rho = \frac{1}{4\pi} (E_r^{ext} - E_r^{int}) = -\frac{\mu \omega}{2\pi c R^2} \cos^2 \theta$$ (29)

In curved spacetime the same quantity can be written as

$$\rho = -\frac{3\mu \omega}{8\pi cm^2} \cos^2 \theta[(1 - 2m/R)^{-1} + \frac{R}{m} \ln(1 - 2m/R) + 1]$$ (30)
Since the effect of curvature increases the electric field intensity near the surface, therefore in curved spacetime the surface charge density is much higher than that in flat spacetime. For a pulsar with mass $1.4M_\odot$ and radius 10 km the surface charge density at the pole in curved spacetime is twice of that in flat spacetime.

The Lorentz invariant scalar product $\mathbf{E}^\text{ext} \cdot \mathbf{B}$ does not vanish. This quantity gives a measure of the force which a co-rotating charged particle feels in the direction of the magnetic field.

In flat spacetime

$$\mathbf{E}^\text{ext} \cdot \mathbf{B} = -\frac{4\mu^2\omega R^2 \cos^3 \theta}{cr^7}$$

leading to an acceleration of a charged particle in the direction of the magnetic field:

$$a = \frac{e \mathbf{E}^\text{ext} \cdot \mathbf{B}}{m_p |\mathbf{B}|} = -\frac{4e}{m_p c} \frac{\mu \omega R^2}{r^4} \cos^3 \theta (3 \cos^2 \theta + 1)^{-1/2}$$

where $m_p$ is the mass of the charged particle and $e$ is its charge. The corresponding quantities in curved spacetime can be obtained by using equations (7), (8) and (24) and are given by

$$\mathbf{E}^\text{ext} \cdot \mathbf{B} = \frac{9\mu^2\omega R^2}{8m^5cr^2} F(r) G(r) \cos^3 \theta$$

and

$$a = \frac{3e}{2m_p c} \frac{\mu \omega R^2}{m^3 r^2} F(r) G(r) \cos^3 \theta \left[ \frac{\cos^2 \theta}{m^2} G^2(r) + \frac{\sin^2 \theta}{r^2} (1 - \frac{2m}{r}) F^2(r) \right]^{-1/2}$$

where

$$F(r) = [(1 - 2m/r)^{-1} + \frac{r}{m} \ln(1 - 2m/r) + 1]$$

$$G(r) = \ln(1 - 2m/r) + \frac{2m}{r} (1 + \frac{m}{r})$$

In Figure 3 we present the variation of acceleration of charged particles with distance by considering the Crab pulsar with a rotational period 33ms. The acceleration has been measured at the angle $\theta = 0^\circ$ to the axis of rotation. Since gravitation greatly increases the electric field intensity near the surface of the star, the acceleration of charged particles is much higher in curved spacetime than that in flat spacetime near the surface. This result
indicates that the radiation spectrum of pulsars may significantly be influenced by the intense gravitational field of neutron stars and requires further attention.

Since in realistic situation the magnetosphere must be filled up with charge plasma, therefore the various quantities discussed in this section may not represent the actual situation. However the effect of curvature remains the same whether the region under consideration is vacuum or not, since the gravitational effect due to the magnetospheric plasma is negligible.

4.2. The Aligned Non-vacuum Rotator

It is now well accepted that the magnetosphere of neutron stars must be filled up with plasma such that $\mathbf{E} \cdot \mathbf{B} = 0$ everywhere within the light cylinder. In the Goldreich-Julian model the source of plasma is assumed to be free field emission from the surface.

In this section we will briefly discuss the effect of spacetime curvature on the induced electric field by considering the aligned non-vacuum rotator model.

In order to investigate the effect of curvature to the induced electric field we consider the Godreich-Julian solution which simply corresponds to extending the interior solution to infinity with space charge density continuing smoothly through the surface. We neglect, for simplicity any effects due to the magnetospheric plasma. However inclusion of the same would not change the general feature of the curvature effect.

Therefore, for this case, equations (17) and (18) express the components of the electric field outside the star in Schwarzschild spacetime with $r$ being extended from just inside the surface to infinity (the superscript ‘int’ should now be ignored).

The corresponding expression in flat spacetime can be written as

$$E(\text{flat}) = \frac{\mu \omega}{c r^2} (\sin^2 \theta, -2 \sin \theta \cos \theta, 0)$$ (37)

Asymptotically as $r \to \infty$, $E(\text{curved}) \to E(\text{flat})$ as it must be the boundary condition.

From equation (10) we obtain the electric field lines in flat spacetime as

$$e(\theta) = \frac{2 \pi \mu \omega}{3c} \left[ \cos^3 \theta - 3 \cos \theta + 2 \right] = \text{constant}$$ (38)

From equation (17) we obtain the same in curved spacetime as

$$e(\theta) = \frac{\pi \mu \omega r^2}{2cm^2} \left[ \cos^3 \theta - 3 \cos \theta + 2 \right]\left[ (1 - 2m/r)^{-1} + \frac{r}{m} \ln(1 - 2m/r) + 1 \right] = \text{constant}$$ (39)
Clearly the electric field lines for flat spacetime is independent of \( r \) whereas those in Schwarzschild background geometry depend on \( r \) only near the surface. At comparatively large distance the field lines for curved spacetime asymptotically become independent of distance and hence it is not possible to plot them at a large distance. Also, since the electric field is continuous from the interior to the exterior of the star for the non-vacuum case, the expressions are independent of the radius of the star.

Taking, as earlier, the Crab pulsar with a period of 33ms we show in Figure 4 the induced electric field lines in curved spacetime in the x-z plane out to 4 stellar radii. Beyond this distance the field lines almost become independent of \( r \) and it is not possible to present them graphically.

Figure 5 shows the complete picture of the non-vacuum magnetosphere in curved spacetime with both the induced electric field lines and the dipole magnetic field lines obtained by using the expression for the magnetic field lines:

\[
b(\theta) = -\frac{3\pi\mu r^2 \sin^2 \theta}{4m^3} \left[ \ln(1 - 2m/r) + \frac{2m}{r} \left(1 + \frac{m}{r}\right) \right] = \text{constant} \tag{40}\]

In both the plots we have taken, for convenience, the electric and the magnetic field lines from the interior of the star and extended it to the exterior. However, far bellow the surface the spacetime metric considered here, cannot describe the geometry of the region, hence in the plots they are not shown at a distance far bellow the surface of the star.

From equations (27) and (28) we notice that the ratio between the electric fluxes in curved and flat spacetime for the vacuum model is the same to that for the non-vacuum case and is given by

\[
\frac{e(\theta)[\text{curved}]}{e(\theta)[\text{flat}]} = \frac{3r^2 F(r)}{4m^2} \tag{41}\]

where \( F(r) \) is given by equation (35).

Hence the effect of spacetime curvature to the electric field lines remains the same in this case as well.

In flat spacetime the space charge density is given by

\[
\sigma = \frac{1}{4\pi} \text{div} \mathbf{E} = -\frac{\mu \omega}{2\pi c r^3} (3 \cos^2 \theta - 1) \tag{42}\]

which is always quadrapolar.
The corresponding expression in curved spacetime can be written as:

\[
\sigma = \frac{3\mu_0}{16\pi \text{cm}^2} \left\{ \left[ \frac{4\sin^2 \theta}{r^4} (1 - 2m/r)^{-1} + \frac{3\sin^2 \theta}{m} \ln(1 - 2m/r) - \frac{2m\sin^2 \theta}{r^2} (1 - 2m/r)^{-2} + \frac{2\sin^2 \theta}{r} \right] + \left( \frac{3\cos^2 \theta - 1}{m} \right) \ln(1 - 2m/r) + \frac{2m}{r} \left( 1 + \frac{m}{r} \right) \right\} \right\} \quad (43)
\]

Figure 6 presents the space charge density as a function of distance from the surface of the Crab pulsar at an angle \( \theta = 0^\circ \) to the axis of rotation. In all the figures the various quantities have been measured in CGS units and their absolute values have been taken in logarithmic scale unless mentioned otherwise.

Since gravitation increases the electric field intensity at the surface, more particles get torn off the surface. The electric field required to pull ions from the molecular chains with the ions distributed in a one dimensional lattice along the chain and with an outer sheath of electrons, is of the order \( 10^{12} \text{ V cm}^{-1} \) (Ruderman & Sutherland 1975). Therefore the effect of gravitation in some pulsars may cause the surface electric field to reach this cut off value and hence may enable to pull ions. However, ions may be torn off from the surface due to other effects (Mitchel 1982). In that case, the inclusion of gravitation would increase the number density of ions, in the same way it increases the number density of electrons.

5. CONCLUSIONS

We have presented a quantitative discussion on the effects of spacetime curvature to the induced electric field of a pulsar. Considering stationary and axisymmetric electromagnetic vector potential in Schwarzschild background geometry the components of the induced electric field that arises due to the rotation of the magnetic dipole, have been derived and compared with that in flat spacetime. It is found that spacetime curvature increases the electric field intensity significantly near the surface of the star. As a consequence, in vacuum magnetosphere the acceleration of charged particles along the direction of the magnetic field increases significantly near the surface. Also the increase in the electric field intensity near the surface results in increasing the surface charge density significantly. The quadrupole electric field lines have been presented for Crab pulsar, as an example, in both curved and flat spacetime and it is found that the difference in the field lines for the curved and the flat spacetimes is well distinguishable upto 40 stellar radii.

In a plasma filled magnetosphere the electric field lines are independent of distance in
flat spacetime but in curved spacetime they depend on $r$ near the surface. However, the field lines in curved spacetime asymptotically become independent of $r$ at large distance. The induced electric field lines in curved spacetime have been presented by taking Crab pulsar, as an example and the combined dipole magnetic field lines and the induced electric field lines near the surface of the star for curved spacetime have been presented as well.

Due to the increase in the electric field intensity near the surface the space charge density of a plasma filled magnetosphere increases significantly from that in flat spacetime. All the quantities measured in curved spacetime, however asymptotically reach their respective values in flat spacetime as a result of the usual boundary condition. Since the ratio of the components of the electric field in curved spacetime to that in flat spacetime is the same, therefore the effects of gravitation on various electromagnetic mechanisms remain the same for all types of magnetospheric models which assume stationary and axisymmetric vector potentials. Hence the present results are very important in the context of radiation mechanisms in pulsars.

Though we have considered the most idealized models of the pulsar magnetosphere the effects of spacetime curvature to the induced electric field would remain the same provided there is no dipole or gravitational radiation. The effect of inertial frame dragging is negligible even for millisecond pulsars but the departure from spherical symmetry due to rapid rotation of the star could alter the scenario significantly. Nevertheless, the present results would provide reasonably well insight on the effect of spacetime curvature to the induced electric field outside a rotating neutron star with its magnetic axis aligned to the rotational axis.

ACKNOWLEDGEMENTS

I am grateful to the referee for many valuable comments and suggestions which have not only improved the clarity of the paper in great extent but also have removed some serious errors in an early version of the manuscript. Thanks are due to B. R. Iyer for discussions.

Solid curves represent field lines for curved spacetime while dashed curves for flat spacetime. The corresponding value assigned to the field line is the same for both curved and flat spacetimes.

FIG 2b. – A closer view of the quadrapole electric field lines shown in Figure 2a.

FIG 3. – The acceleration of an electron in the direction of the magnetic field at an angle $\theta = 0^\circ$ to the axis of rotation for Crab pulsar as a function of distance from the stellar surface. Solid curve – curved spacetime; dashed curve – flat spacetime.

FIG 4. – The induced electric field lines in curved spacetime for the Crab pulsar with a period 33ms and $\mu = 2 \times 10^{30} G cm^3$ by considering the magnetosphere to be plasma filled (see text).

FIG 5. – The combined dipole magnetic and induced electric field lines in curved spacetime for the Crab pulsar with $\mu = 2 \times 10^{30} G cm^3$ by considering plasma filled magnetosphere. Solid curves represent the induced electric field lines while dashed curves for the dipole magnetic filed lines.

FIG 6. – The space charge density at an angle $\theta = 0^\circ$ to the axis of rotation for the Crab pulsar as a function of distance from the stellar surface. Solid curve – curved spacetime; dashed curve – flat spacetime.
