Multitime maximum principle approach of minimal submanifolds and harmonic maps

Constantin Udriște

Abstract

Some optimization problems coming from the Differential Geometry, as for example, the minimal submanifolds problem and the harmonic maps problem are solved here via interior solutions of appropriate multitime optimal control problems.

Section 1 underlines some science domains where appear multitime optimal control problems. Section 2 (Section 3) recalls the multitime maximum principle for optimal control problems with multiple (curvilinear) integral cost functionals and $m$-flow type constraint evolution. Section 4 shows that there exists a multitime maximum principle approach of multitime variational calculus. Section 5 (Section 6) proves that the minimal submanifolds (harmonic maps) are optimal solutions of multitime evolution PDEs in an appropriate multitime optimal control problem. Section 7 uses the multitime maximum principle to show that of all solids having a given surface area, the sphere is the one having the greatest volume. Section 8 studies the minimal area of a multitime linear flow as optimal control problem. Section 9 contains commentaries.

Mathematics Subject Classification: 49K20, 58E20, 53C42.

Key words: multitime maximum principle, minimal submanifolds, harmonic maps, isoperimetric constraints.

1 Origin of multitime optimal control problems

The original results in this paper show that the minimal submanifolds (see [1], [3], [4], [22], [31]) and the harmonic maps (see [2]) are solutions
of multitime optimal control problems (see [5]-[30]). In this way we change the traditional geometrical viewpoint, looking at a minimal submanifold or at a harmonic map as solution in a multitime optimal control system via the multitime maximum principle. Problems of this type are among the most challenging in Differential Geometry and Control Theory while being among the most important for various applications.

Near Differential Geometry, there are many domains of science containing multitime optimal control problems: Material Strength (the description of torsion of prismatic bars in the elastic case as well as in the elastic-plastic case), Fluid Mechanics (the motion of fluid substances, Navier-Stokes PDE written as first order PDE), Magnetohydrodynamics (Maxwell-Vlasov PDE, Navier-Stokes PDE) etc. Of course, to describe some m-dimensional objects as optimal evolution maps, a deeply understanding of the meaning of evolution is necessary. Our results confirm that the basic ideas of Lev S. Pontryagin, Lawrence C. Evans and Jacques-Louis Lions are still surviving for optimal control problems governed by normal first order PDEs.

## 2 Optimal Control Problem with Multiple Integral Cost Functional

Let us analyze a multitime optimal control problem based on a multiple integral cost functional and m-flow type PDE constraints [14]-[15], [18], [19], [28], [30]:

$$\max_{u(\cdot)} I(u(\cdot)) = \int_{\Omega_{t_0}} L(t, x(t), u(t)) dt$$

subject to

$$\frac{\partial x^i}{\partial t^\alpha}(t) = X^i_\alpha(t, x(t), u(t)), i = 1, ..., n; \alpha = 1, ..., m,$$

$$u(t) \in U, \ t \in \Omega_{t_{0}}, \ x(0) = x_0, \ x(t_0) = x_{t_0}.$$
\((X^i_\alpha(t,x(t),u(t)))\) are \(C^1\) vector fields satisfying the complete integrability conditions (\(m\)-flow type problem), i.e., \(D_\beta X_\alpha = D_\alpha X_\beta\) \((D_\alpha\) is the total derivative operator) or

\[
\left(\frac{\partial X_\alpha}{\partial u^\gamma} \delta_\beta^\gamma - \frac{\partial X_\beta}{\partial u^\gamma} \delta_\alpha^\gamma \right) \frac{\partial u^\alpha}{\partial t^\gamma} = [X_\alpha,X_\beta] + \frac{\partial X_\beta}{\partial t^\alpha} - \frac{\partial X_\alpha}{\partial t^\beta},
\]

where \([X_\alpha,X_\beta]\) means the \textit{bracket} of vector fields. The complete integrability hypothesis constrains the set of all admissible controls (satisfying the complete integrability conditions)

\[
\mathcal{U} = \{ u: \mathbb{R}_+^m \rightarrow U \mid D_\beta X_\alpha = D_\alpha X_\beta \}
\]

and the admissible states.

To formulate the \textit{multitime maximum principle} we need the \textit{control Hamiltonian}

\[
H(t,x(t),u(t),p(t)) = L(t,x(t),u(t)) + p^\alpha_i(t)X^i_\alpha(t,x(t),u(t)).
\]

\textbf{Theorem 1.1} (multitime maximum principle; necessary conditions). Suppose that the previous optimal control problem, with \(X, X^i_\alpha\) of class \(C^1\), has an interior solution \(\hat{u}(t) \in U\) which determines the \(m\)-sheet of state variable \(x(t)\). Then there exists a \(C^1\) costate \(p(t) = (p^\alpha_i(t))\) defined over \(\Omega_{t_0}\) such that the relations

\[
\frac{\partial p^\alpha_j}{\partial t^\alpha}(t) = - \frac{\partial H}{\partial x^j}(t,x(t),\hat{u}(t),p(t)), \forall t \in \Omega_{t_0},
\]

\[
\delta_{\alpha\beta} p^\beta_j(t)n^\beta(t)|_{\partial\Omega_{t_0}} = 0 \ (\text{orthogonality or tangency}),
\]

\[
\frac{\partial x^j}{\partial t^\alpha}(t) = \frac{\partial H}{\partial p^\alpha_j}(t,x(t),\hat{u}(t),p(t)), \forall t \in \Omega_{t_0}, \ x(0) = x_0
\]

and

\[
H_{u^\alpha}(t,x(t),\hat{u}(t),p(t)) = 0, \forall t \in \Omega_{t_0}
\]

hold.

\textbf{Remark 1.2} If the optimal control \(\hat{u}(t) \in U\) is not an interior point, then instead of critical point condition we have

\[
H((t,x(t),\hat{u}(t),p(t)) = \max_u H(t,x(t),u,p(t)).
\]

\textbf{Theorem 1.2} Multitime Global Maximality. The foregoing problem has a global solution \((\hat{x}(\cdot),\hat{u}(\cdot))\) if and only if the multiple integral functional \(\int_{\Omega_{t_0}} H(t,x(t),u(t),p(t))dt\) is incave with respect to \(u\).
3 Optimal Control Problem with Curvilinear Integral Cost Functional

A multitime optimal control problem whose cost functional is the sum between a path independent curvilinear integral (mechanical work, circulation) and a function of the final event, and whose evolution PDE is an $m$-flow, has the form [14], [15]-[17], [19], [23], [24], [30]

$$
\max_{u(\cdot)} J(u(\cdot)) = \int_{t_0}^{t_n} L_\alpha(t, x(t), u(t)) dt^\alpha + g(x(t_0))
$$

subject to

$$
\frac{\partial x^i}{\partial t^\alpha}(t) = X^i_\alpha(t, x(t), u(t)), \quad i = 1, ..., n, \quad \alpha = 1, ..., m,
$$

$$
u(t) \in \mathcal{U}, \quad t \in \Omega_{t_0}, \quad x(0) = x_0, \quad x(t_0) = x_{t_0}.
$$

This problem requires the following data: the multitime (multi-parameter of evolution) $t = (t^\alpha) \in \mathbb{R}_+^m$; an arbitrary $C^1$ curve $\Gamma_{t_0}$ joining the diagonal opposite points $0 = (0, ..., 0)$ and $t_0 = (t_0^1, ..., t_0^m)$ in the parallelepiped $\Omega_{t_0} = [0, t_0]$ (multitime interval) in $\mathbb{R}_+^m$ endowed with the product order; a $C^2$ state vector $x : \Omega_{t_0} \to \mathbb{R}^k$, $x(t) = (x^i(t))$; a $C^1$ control vector $u : \Omega_{t_0} \to \mathcal{U} \subseteq \mathbb{R}^k$, $u(t) = (u^a(t))$, $a = 1, ..., k$; a running cost $L_\alpha(t, x(t), u(t)) dt^\alpha$ as a nonautonomous closed (completely integrable) Lagrangian 1-form, i.e., it satisfies $D_\beta L_\alpha = D_\alpha L_\beta$ ($D_\alpha$ is the total derivative operator) or

$$
\left( \frac{\partial L_\alpha}{\partial u^a} \delta_\beta^\gamma - \frac{\partial L_\beta}{\partial u^a} \delta_\alpha^\gamma \right) \frac{\partial u^a}{\partial t^\gamma} = X^i_\alpha \frac{\partial L_\beta}{\partial x^i} - X^i_\beta \frac{\partial L_\alpha}{\partial x^i} + \frac{\partial L_\beta}{\partial t^\alpha} - \frac{\partial L_\alpha}{\partial t^\beta},
$$

the terminal cost functional $g(x(t_0))$; the $C^1$ vector fields $X_\alpha = (X^i_\alpha)$ satisfying the complete integrability conditions ($m$-flow type problem), i.e., $D_\beta X_\alpha = D_\alpha X_\beta$ or

$$
\left( \frac{\partial X_\alpha}{\partial u^a} \delta_\beta^\gamma - \frac{\partial X_\beta}{\partial u^a} \delta_\alpha^\gamma \right) \frac{\partial u^a}{\partial t^\gamma} = [X_\alpha, X_\beta] + \frac{\partial X_\beta}{\partial t^\alpha} - \frac{\partial X_\alpha}{\partial t^\beta},
$$

where $[X_\alpha, X_\beta]$ means the bracket of vector fields. Some of the previous hypothesis select the set of all admissible controls (satisfying the complete integrability conditions, eventually, a.e.)

$$
\mathcal{U} = \{ u : \mathbb{R}_+^m \to \mathcal{U} \mid D_\beta L_\alpha = D_\alpha L_\beta, \quad D_\beta X_\alpha = D_\alpha X_\beta, \text{ a.e.} \}.
$$

The set $\mathcal{U}$ does not contain always the constant controls, but it contain sure controls which are continuous at the right (in the sense of product order).

The previous PDE evolution system is equivalent to the path-independent curvilinear integral equation

$$
x(t) = x(0) + \int_{t_0}^t X_\alpha(s, x(s), u(s)) ds^\alpha,
$$

4
where $\gamma_{0t}$ is an arbitrary piecewise $C^1$ curve joining the opposite diagonal points 0 and $t$ of the parallelepiped $\Omega_{0t} = [0, t] \subset \Omega_{00} = [0, t_0]$.

In the multitime optimal control problems with path independent integrals, it is enough to use increasing curves.

**Definition 2.1** A piecewise $C^1$ curve $\gamma_{0t} : s^\alpha = s^\alpha(\tau), \tau \in [\tau_0, \tau_1], s(\tau_0) = 0, s(\tau_1) = t_0$ is called increasing if the tangent vector $\dot{s} = (\dot{s}^\alpha)$ satisfies $\dot{s}^\alpha \geq 0$, with $||\dot{s}|| = 0$ only at isolated points.

If we use the control Hamiltonian 1-form

$$H_\alpha(t, x(t), u(t), p(t)) = L_\alpha(t, x(t), u(t)) + p_i(t)X^i_\alpha(t, x(t), u(t)),$$

we can formulate the **multitime maximum principle**

**Theorem 2.1 Multitime Maximum Principle.** Suppose that the previous problem, with $L_\alpha, X^i_\alpha$ of class $C^1$, has an interior solution $\hat{u}(t) \in U$ which determines the $m$-sheet of state variable $x(t)$. Then, there exists a $C^1$ vector costate $p(t) = (p_i(t))$ defined over $\Omega_{0t_0}$ such that the following relations hold:

$$\frac{\partial p_j}{\partial t^\alpha}(t) = -\frac{\partial H_\alpha}{\partial x^j}(t, x(t), \hat{u}(t), p(t)), \forall t \in \Omega_{0t_0}, p_j(t_0) = 0,$$

$$\frac{\partial x^j}{\partial t^\alpha}(t) = \frac{\partial H_\alpha}{\partial p_j}(t, x(t), \hat{u}(t), p(t)), \forall t \in \Omega_{0t_0}, x(0) = x_0,$$

$$\frac{\partial H_\alpha}{\partial u^\alpha}(t, x(t), \hat{u}(t), p(t)) = 0, \forall t \in \Omega_{0t_0}.$$

**Remark 2.1** If the optimal control $\hat{u}(t) \in U$ is not an interior point, then instead of critical point condition we have

$$H_\alpha((t, x(t), \hat{u}(t), p(t)) = \max_u H_\alpha(t, x(t), u, p(t)).$$

**Theorem 2.2 Multitime Global Maximality.** The foregoing problem has a global solution $(\hat{x}(\cdot), \hat{u}(\cdot))$ if and only if the curvilinear integral functional $\int_{\Gamma_{0t_0}} H_\alpha(t, x(t), u(t), p(t))dt^\alpha$ is incave with respect to $u$.

4 Multitime maximum principle

approach of variational calculus

In fact we show that the multitime maximum principle motivates the multitime Euler-Lagrange or Hamilton PDEs.
4.1 Case of multiple integral action

Suppose that the evolution system is reduced to a completely integrable system

\[ \frac{\partial x^i}{\partial \alpha}(t) = u^i_{\alpha}(t), \quad x(0) = x_0, \quad t \in \Omega_{\Omega_0} \subset \mathbb{R}^m_+, \quad (PDE) \]

and the functional is a multiple integral

\[ I(u(\cdot)) = \int_{\Omega_{\Omega_0}} X(t, x(t), u(t)) dt, \quad (I) \]

where \( \Omega_{\Omega_0} \) is the parallelepiped fixed by the diagonal opposite points \( 0 = (0, ..., 0) \) and \( t_0 = (t_0^1, ..., t_0^m) \), the running cost \( X(t, x(t), u(t)) dt \) is a Lagrangian \( m \)-form.

The associated basic control problem leads necessarily to the multitime maximum principle. Therefore, to solve it we need the control Hamiltonian

\[ H(t, x, p_0, p, u) = X(t, x, u) + p_\alpha^i u^i_{\alpha} \]

and the adjoint PDEs

\[ \frac{\partial p_\alpha^i}{\partial t^\alpha}(t) = -\frac{\partial X}{\partial x^i}(t, x(t), u(t)). \quad (ADJ) \]

Suppose the simplified multitime maximum principle is applicable

\[ \frac{\partial H}{\partial u^\gamma_j} = \frac{\partial X}{\partial u^\gamma_j} + p_\gamma^i = 0, \quad p_\gamma^i = -\frac{\partial X}{\partial u^\gamma_j}, \quad u^i_{\alpha} = x^i_{\alpha}. \]

Suppose the function \( X \) is dependent on \( x \) (a strong condition!). We eliminate \( p^\gamma_i \) using the adjoint PDE. It follows the multitime Euler-Lagrange PDEs

\[ \frac{\partial X}{\partial x^i} - D_{\alpha} \left( \frac{\partial X}{\partial x^i_{\alpha}} \right) = 0. \]

4.2 Case of path independent curvilinear integral action

First, suppose that the evolution system is reduced to a completely integrable system

\[ \frac{\partial x^i}{\partial \alpha}(t) = u^i_{\alpha}(t), \quad x(0) = x_0, \quad t \in \Omega_{\Omega_0} \subset \mathbb{R}^m_+, \quad (PDE) \]

and the functional is a path independent curvilinear integral

\[ J(u(\cdot)) = \int_{\Gamma_{\Omega_0}} L_\beta(t, x(t), u(t)) dt^\beta, \quad u = (u^i_{\alpha}), \quad (J) \]
where $\Gamma_{0t_0}$ is an arbitrary piecewise $C^1$ curve joining the points 0 and $t_0$, the running cost $\omega = L_\beta(t, x(t), u(t))dt^\beta$ is a closed (completely integrable) Lagrangian 1-form.

The associated basic control problem leads necessarily to the multitime maximum principle. Therefore, to solve it we need the control Hamiltonian 1-form

$$H_\beta(t, x, p_0, p, u) = L_\beta(t, x, u) + p_\gamma u_\gamma$$

and the adjoint PDEs

$$\frac{\partial p_\gamma}{\partial t^\beta}(t) = -\frac{\partial L_\beta}{\partial x^\gamma}(t, x(t), u(t)). \quad (ADJ)$$

Suppose the simplified multitime maximum principle is applicable, i.e.,

$$\frac{\partial H_\beta}{\partial u^i_\gamma} = \frac{\partial L_\beta}{\partial u^i_\gamma} + p_\gamma \delta^\gamma_\beta = 0, \quad p_\gamma \delta^\gamma_\beta = -\frac{\partial L_\beta}{\partial u^i_\gamma}, \quad u^i_\gamma = x^i_\gamma.$$

We accept that the functions $L_\beta$ are dependent on $x$ (a strong condition!). Then $(ADJ)$ shows that

$$p_\gamma(t) = p_\gamma(0) - \int_{\Gamma_{0t}} \frac{\partial L_\beta}{\partial x^\gamma}(s, x(s), u(s))ds^\beta,$$

where $\Gamma_{0t}$ is an arbitrary piecewise $C^1$ curve joining the points 0, $t \in \Omega_{0t_0}$. From the foregoing last three relations, it follows

$$-\frac{\partial L_\beta}{\partial x^\gamma}(t, x(t), u(t)) = \delta^\gamma_\beta p_\gamma(0) - \delta^\gamma_\beta \int_{\Gamma_{0t}} \frac{\partial L_\lambda}{\partial x^\gamma}(s, x(s), u(s))ds^\lambda.$$

If $X_\beta^\gamma$ are functions of class $C^2$, then applying the divergence operator $D_\gamma = \frac{\partial}{\partial t^\gamma}$, we find the multitime Euler-Lagrange PDEs

$$\frac{\partial L_\beta}{\partial x^\gamma} - D_\gamma \frac{\partial L_\beta}{\partial x^\gamma} = 0.$$

5 Minimal submanifolds as optimal evolutions

The minimal submanifolds are characterized by zero mean curvature. These become an area of intense mathematical and scientific study over the past 15 years, specifically in the areas of molecular engineering and materials sciences due to their anticipated nanotechnology applications. The most extensive meeting ever held on the subject, in its 250-year history, was organized in 2001 at Clay Mathematics...
Institute. In spite of all these efforts, the traditional thinking about minimality was not change.

Recently, I gave a new approach to the theory of minimal surfaces [22], [29] changing the traditional approach into a new one based on solutions in a two-time optimal control system via the multitime maximum principle. More, our recent studies [5]-[30] show the efficiency of approaching some classical problems using techniques of multitime optimal control or multitime modeling.

Let \( \Omega_{0\tau} \) be an interval fixed by the diagonal opposite points \( 0, \tau \in \mathbb{R}_+^m \). On an \( n \)-dimensional Riemannian manifold \((M, g_{ij})\) we introduce the multitime controlled dynamics

\[
\frac{\partial x^i}{\partial t^\alpha}(t) = u^i_\alpha(t), \quad i = 1, \ldots, n; \alpha = 1, \ldots, m; \quad (PDE)
\]

where \( t = (t^1, \ldots, t^m) \in \Omega_{0\tau}, \ x^i(0) = x^i_0, \ x^i(\tau) = x^i_1. \)

The metric \( g_{\alpha\beta}(t) = g_{ij}(x(t))u^i_\alpha(t)u^j_\beta(t) \) determines the volume

\[
\int_{\Omega_{0\tau}} \sqrt{\det(g_{\alpha\beta})} \ dt
\]

of the \( m \)-sheet \( x(t), \ t \in \Omega_{0\tau} \) and this defines the functional

\[
V(u(\cdot)) = -\int_{\Omega_{0\tau}} \sqrt{\det(g_{\alpha\beta})} \ dt. \quad (V)
\]

Multitime optimal control problem of minimal submanifolds:

\[
\max_{u(\cdot)} V(u(\cdot))
\]

subject to

\[
\frac{\partial x^i}{\partial t^\alpha}(t) = u^i_\alpha(t), \quad i = 1, \ldots, n; \alpha = 1, \ldots, m,
\]

\[
u(t) \in U, \ t \in \Omega_{0\tau}; \ x(0) = x_0, \ x(\tau) = x_1.
\]
To solve the multitime optimal control problem of minimal submanifolds, we apply the multitime maximum principle. In general notations, we have

\[ x = (x^i), \quad u = (u_\alpha) = (u^i_\alpha), \quad p = (p^\alpha) = (p^i_\alpha), \quad i = 1, \ldots, n; \quad \alpha = 1, \ldots, m, \]

\[ X_\alpha(x(t), u(t)) = u_\alpha(t), \quad L(x(t), u(t)) = -\sqrt{\det(g_{\alpha\beta})} \]

and the control Hamiltonian is

\[ H(x, u, p) = p^\alpha_i X^i_\alpha(x, u) + p_0 L(x, u). \]

Taking \( p_0 = 1 \), the adjoint dynamics says

\[ \frac{\partial p^\alpha_i}{\partial t^\alpha} = -\frac{\partial H}{\partial x^i}. \quad (ADJ) \]

On the other hand, we have to maximize \( H(x, u, p) \) with respect to the control \( u \), hence

\[ \frac{\partial H}{\partial u^i_\alpha} = \frac{\partial L}{\partial u^i_\alpha} + p^\alpha_i = 0. \]

This necessary condition (critical point) is also sufficient since the foregoing Hamiltonian \( H(x, u, p) \) is an incave function with respect to \( u \). Indeed, the Lagrangian \( L(x, u) \) is an incave function with respect to \( u \), because it has any critical point, and the Hamiltonian \( H \) is obtained from \( L \) adding a linear term.

Having in mind that \( x^i_\alpha = u^i_\alpha \), we eliminate \( p^\alpha_i \) using the adjoint PDE. It follows the multitime Euler-Lagrange PDEs

\[ \frac{\partial L}{\partial x^i} - D_\alpha \left( \frac{\partial L}{\partial x^i_\alpha} \right) = 0 \]

or

\[ \frac{\partial L}{\partial x^i} - D_\alpha \left( \frac{\partial L}{\partial g^{\beta\gamma}} \frac{\partial g^{\beta\gamma}}{\partial x^i_\alpha} \right) = 0. \]

Summarizing, we obtain

**Theorem 5.1.** A \( C^2 \) solution of the previous optimal control problem is a solution of the boundary problem

\[ \frac{\partial L}{\partial x^i} - D_\alpha \left( g_{\alpha\beta} g^{\beta\gamma} \frac{\partial g^{\gamma\delta}}{\partial x^i_\alpha} \right) = 0, \quad x(0) = x_0, \quad x(t_0) = x_{t_0} \]

i.e., it is a minimal submanifold.

The familiar relativistic free particle and the dual string, which provides a dynamical model of hadrons, are described by the PDEs in Theorem 5.1.
6 Harmonic maps as optimal evolutions

Traditionally, the Harmonic maps are solutions to a natural geometric variational problem motivated by some fundamental ideas from differential geometry, in particular geodesics, minimal surfaces, and harmonic functions. Harmonic maps are also closely related to nonlinear partial differential equations, holomorphic maps in several complex variables, the theory of stochastic processes, the nonlinear field theory in theoretical physics, and the theory of liquid crystals in materials science.

Our recent papers change the traditional geometrical viewpoint, looking at a harmonic map as solution in a multitime optimal control system via the multitime maximum principle.

Let $\Omega_{0}^{\tau}$ be an interval fixed by the diagonal opposite points $0, \tau \in R_{+}^{m}$. Let $h_{\alpha\beta}$ be a Riemannian metric on $R_{+}^{m}$. On the Riemannian manifold $(M, g_{ij})$ we introduce the multitime controlled dynamics

$$\frac{\partial x^{i}(t)}{\partial u^{\alpha} (t)} = u_{\alpha}^{i}(t), \ i = 1, ..., n; \alpha = 1, ..., m; \quad (PDE)$$

where $u = (u_{\alpha}) = (u_{\alpha}^{i}) : \Omega_{0r} \rightarrow R^{mn}$ represents two open-loop $C^{1}$ control vectors, linearly independent, eventually fixed on the boundary $\partial \Omega_{0r}$. The complete integrability conditions of the (PDE) system, restrict the set of controls to

$$U = \left\{ u = (u_{\alpha}) = (u_{\alpha}^{i}) \mid \frac{\partial u_{\alpha}^{i}}{\partial t^{\beta}} (t) = \frac{\partial u_{\beta}^{i}}{\partial t^{\alpha}} (t) \right\}.$$

A $C^{2}$ solution of (PDE) system is a map (m-sheet) $\sigma : x^{i} = x^{i}(t^{1}, ..., t^{m})$.

We introduce the energy density $\frac{1}{2} h_{\alpha\beta}^{ij}(t) g_{ij}(x(t)) u_{\alpha}^{i}(t) u_{\beta}^{j}(t)$ of the m-sheet $x(t), t \in \Omega_{0r}$ and the energy functional (elastic deformation energy)

$$E(u(\cdot)) = -\frac{1}{2} \int_{\Omega_{0r}} h_{\alpha\beta}^{ij}(t) g_{ij}(x(t)) u_{\alpha}^{i}(t) u_{\beta}^{j}(t) \ dt. \quad (E)$$

The energy density is defined by the trace of the induced metric $g_{\alpha\beta} = g_{ij} u_{\alpha}^{i} u_{\beta}^{j}$ with respect to the metric $h_{\alpha\beta}^{ij}$.

Multitime optimal control problem of harmonic maps:

$$\max_{u(\cdot)} E(u(\cdot))$$

subject to
\[
\frac{\partial x^i}{\partial t^\alpha}(t) = u^i_\alpha(t), \; i = 1, ..., n; \; \alpha = 1, ..., m;
\]
\[
u(t) \in \mathcal{U}, \; t \in \Omega_0; \; x(0) = x_0, \; x(\tau) = x_1.
\]

To solve the previous problem we apply the multitime maximum principle. In general notations, we have
\[
x = (x^i), \; u = (u_\alpha) = (u^i_\alpha), \; p = (p^\alpha) = (p^i_\alpha), i = 1, ..., n; \; \alpha = 1, ..., m,
\]
\[
X_\alpha(x(t), u(t)) = u_\alpha(t), \; L(x(t), u(t)) = -\frac{1}{2} h^{\alpha\beta}(t) g_{ij}(x(t)) u^i_\alpha(t) u^j_\beta(t)
\]
and the control Hamiltonian is
\[
H(x, u, p) = p^i_\alpha X^i_\alpha(x, u) + p_0 L(x, u).
\]

Taking \(p_0 = 1\), the adjoint dynamics says
\[
\frac{\partial p^\alpha_i}{\partial t^\alpha} = -\frac{\partial H}{\partial x^i} \quad (\text{ADJ})
\]

On the other hand, we have to maximize \(H(x, u, p)\) with respect to the control \(u\), hence
\[
\frac{\partial H}{\partial u^i_\alpha} = \frac{\partial L}{\partial u^i_\alpha} + p^\alpha_i = 0.
\]

This necessary condition (critical point) is also sufficient since the Hamiltonian \(H(x, u, p)\) is a concave (and hence incave) function with respect to \(u\). In fact, the Lagrangian \(L(x, u)\) is an incave function with respect to \(u\), because it has any critical point, and the Hamiltonian \(H\) is obtained from \(L\) adding a linear term.

We eliminate \(p^\alpha_i\) using the adjoint PDE. It follows the multitime Euler-Lagrange PDEs
\[
\frac{\partial L}{\partial x^i} - D_\alpha \left( \frac{\partial L}{\partial x^i_\alpha} \right) = 0.
\]

Summarizing, we obtain

**Theorem 6.2.** A \(C^2\) solution of the previous optimal control problem is a harmonic map.

**Remark.** It is possible to extend the notion of harmonic maps to much less regular maps, which belong to the Sobolev space \(H^1(N, M)\) of maps from \((N, h)\) into \((M, g)\) with finite energy. The above equation is true but only in the distribution sense and we speak of weakly harmonic maps.
7 Minimal volume at constant area as optimal control problem

Suppose that $D$ is a compact set of $\mathbb{R}^m = \{(t^1, ..., t^m)\}$ with a piecewise smooth $(m-1)$-dimensional boundary $\partial D$. The volume $\int_D dt^1 ... dt^m$ of the domain $D$ is related to the flux of the position vector $t = (t^\alpha)$ through the closed hypersurface $\partial D$ by the Gauss-Ostrogradski formula

$$m \int_D dt^1 ... dt^m = \int_{\partial D} \delta_{\alpha\beta} t^\alpha N^\beta \, d\sigma,$$

where $N = (N^\beta)$ is the exterior unit normal vector field on $\partial D$. On the other hand, the area of $\partial D$ is $\int_{\partial D} d\sigma$. Introducing a parametrization on $\partial D$, whose domain is $U \subset \mathbb{R}^{m-1}$, we have $d\sigma = ||N|| d\eta$, where $N = ||\mathcal{N}|| N$ and $\eta$ is an $(m-1)$-form.

Let us show that of all solids having a given surface area, the sphere is the one having the greatest volume. To prove this statement, we take the normal vector field $\mathcal{N}$ as a control - a very interesting idea of my PhD student Andreea Bejenaru - and we formulate the multitime optimal control problem with isoperimetric constraint

$$\max_{\mathcal{N}} \int_U \delta_{\alpha\beta} t^\alpha \mathcal{N}^\beta(t) \, d\eta \quad \text{subject to} \quad \int_U \sqrt{\delta_{\alpha\beta} \mathcal{N}^\alpha \mathcal{N}^\beta} \, d\eta = \text{const.}$$

Using the Hamiltonian

$$H = \delta_{\alpha\beta} t^\alpha \mathcal{N}^\beta - p \sqrt{\delta_{\alpha\beta} \mathcal{N}^\alpha \mathcal{N}^\beta}, \quad p = \text{const.},$$

the critical point condition, in the multitime maximum principle, gives

$$0 = \frac{\partial H}{\partial \mathcal{N}} = t - pN.$$

Since the Hamiltonian is a concave function of $\mathcal{N}$, the critical point is a maximum point. This confirms that $D$ is the sphere $||t||^2 \leq p^2$ in $\mathbb{R}^m$.

Remark. In the optimal control problems, the Stokes theorem reads: Let $\omega$ be a controlled $(p-1)$-form, $1 \leq p \leq m$, with compact support on the $p$-dimensional submanifold $D$. If $\partial D$ denotes the boundary of $D$ with its induced orientation, then $\int_{\partial D} \omega = \int_D d\omega$, where $d$ is the exterior derivative. Consequently, we can use as an action functional either those defined by the left hand member of the Stokes formula or those defined by the right hand member, eventually with new constraints.
8 Maximal area constrained by a multitime linear flow

Let \((M, g)\) be a Riemannian manifold and \((TM, G = g + g)\) be its tangent bundle. Let \(\tilde{S} : \Omega_{00} \rightarrow TM\) be an \(m\)-sheet and suppose that \(S\) is expressed locally by \(x^i = x^i(t), y^j = y^j(t)\) with respect to the induced coordinates \((x^i, y^j)\) in \(TM\), and \(t \in \Omega_{00}\) as the multitime evolution parameter. Then the \(m\)-sheet \(S = \pi \tilde{S}\) in \(M\) is called the projection of the \(m\)-sheet \(\tilde{S}\) and is represented locally by \(x^i = x^i(t)\). Now let \(\xi = \xi^i(x) \frac{\partial}{\partial x^i}\) be a vector field on \(M\) tangent to \(S\). Let \(\xi^i = \xi^i(x) \frac{\partial}{\partial y^i}\) be the vertical lift to \(TM\). Let \(y = y^i \frac{\partial}{\partial y^i}\) be the Liouville vector field on \(TM\).

Let \((\xi(t) = \xi(x(t)), y(t))\) be the solution of the linear controlled \(m\)-flow

\[
\frac{\partial \xi^i}{\partial t^\alpha} = A^i_{j\alpha}(t) \xi^j(t) + A^i_{n+j\alpha}(t) y^j(t) + B^i_\alpha(t) u^\alpha(t),
\]

\[
\frac{\partial y^j}{\partial t^\alpha} = A^{n+j}_j(t) \xi^j(t) + A^{n+j+i}_\alpha(t) y^i(t) + B^{n+i}_\alpha(t) u^\alpha(t),
\]
on \(TM\). On the tangent bundle we use the area 1-form

\[
\omega = \frac{1}{2} \left( g_{ij}(x) \xi^i(x) \delta y^j(x) - g_{ij}(x) y^i(x) \delta \xi^j(x) \right)
\]

\[
\delta y^i = dy^i + \Gamma^i_{jk} y^j dx^k, \quad \delta \xi^i = d\xi^i + \Gamma^i_{jk} \xi^j dx^k,
\]
where \(\Gamma^i_{jk}\) is the Riemannian connection on \(M\). Giving a closed curve \(\tilde{C}\) on the image of \((\xi(t), y(t))\), we introduce the area

\[
\sigma = \frac{1}{2} \int_{\tilde{C}} \left( g_{ij}(x) \xi^i(x) \delta y^j(x) - g_{ij}(x) y^i(x) \delta \xi^j(x) \right).
\]

To find this area, we introduce the pullback

\[
\frac{1}{2} \left( g_{ij}(x(t)) \xi^i(t) y^j_\alpha(t) - g_{ij}(x(t)) y^i(t) x^j_\alpha(t) \right) dt^\alpha.
\]

Then, the curvilinear integral

\[
\sigma(u(\cdot)) = \frac{1}{2} \int_{\tilde{C}} \left( g_{ij}(x(t)) \xi^i(t) y^j_\alpha(t) - g_{ij}(x(t)) y^i(t) x^j_\alpha(t) \right) dt^\alpha
\]
is the area of a piece from the \(m\)-surface \((\xi(t), y(t))\) bounded by the curve \(C = \pi(\tilde{C})\).

We formulate the multitime optimal control problem: \(\max_{u(\cdot)} \sigma(u(\cdot))\) subject to the foregoing controlled \(m\)-flow. The Hamiltonian 1-form

\[
H_\alpha = \frac{1}{2} \left( g_{ij}(x(t)) x^i(t) y^j_\alpha(t) - g_{ij}(x(t)) y^i(t) x^j_\alpha(t) \right)
\]
is linearly affine with respect to the control variables, i.e., this Hamiltonian 1-form can be written as
\[ H_\alpha = L_\alpha + M_\alpha u_\alpha, \]
where
\[ M_\alpha(t) = p_i(t)B^{ij}_a(t) + q_i(t)B^{n+i}_a(t), \]
are the switching functions. In general, there will be no extremum unless control variables are bounded, in which case they are expected to be at the boundary of the admissible region (see, linear optimization, simplex method). Suppose \(-1 \leq u_\alpha \leq 1\). When the multitime maximum principle is applied to this type of problems, the optimal control \(u^{*}_\alpha\) must satisfies
\[ u^{*}_\alpha = \begin{cases} 
1 & \text{for } M_\alpha(t) > 0 \\
? & \text{for } M_\alpha(t) = 0 \\
-1 & \text{for } M_\alpha(t) < 0,
\end{cases} \]
for each \(\alpha = 1, ..., m\). This optimal control is discontinuous since each component jumps from a minimum to a maximum and vice versa in response to each change in the sign of each \(M_\alpha(t)\) (switching functions). The optimal control \(u^{*}_\alpha\) is called a bang bang control.

\section{Conclusions}
This paper refers to basic problems in control the partial differential equations of differential geometry. The original results are meaningful and useful for explaining many real world phenomena based on optimal controlled multitime evolutions. They shows that some dreams issuing from the papers of Lev S. Pontryaguin, Lawrence C. Evans and Jacques-Louis Lions are now partially covered by the multitime maximum principle. Of course, to pass from the previous local theory to a global one, we need another more flexible formulation of a smooth multitime optimal control problem involving two Riemannian manifolds.

\textbf{Acknowledgements:} Partially supported by University Politehnica of Bucharest, and by Academy of Romanian Scientists, Bucharest, Romania.

Some ideas were presented at The International Conference of Differential Geometry and Dynamical Systems (DGDS-2010), 25-28 August 2010, University Politehnica of Bucharest, Bucharest, Romania.
Dedicated to Lawrence C. Evans, Lev S. Pontryagin and Jacques-Louis Lions for their seminal contributions to optimal control theory.
