(Dated: November 10, 2018)

Bell-inequality violation and entanglement, measured by Wootters’ concurrence and negativity, of two qubits initially in Werner or Werner-like states coupled to thermal reservoirs are analyzed within the master equation approach. It is shown how this simple decoherence process leads to generation of states manifesting the relativity of two-qubit entanglement measures.

I. INTRODUCTION

Quantum nonlocality, responsible for violation of Bell-type inequalities [1, 2], and entanglement (inseparability) are the fundamental resources of modern quantum-information theory and still the most surprising features of quantum mechanics (see, e.g., [3]). It is therefore desirable to investigate the degrees of the Bell-inequality violation and of the entanglement of a quantum state not only in relation to efficiency of quantum-information processing, but also to understand better subtle aspects of the physical nature.

It is well-known that pure states [4] or a mixture of two Bell states violate Bell inequalities whenever they are entangled. So, one could naively think that the only mixed states that do not violate the Bell inequalities are separable states. However, Werner [5] demonstrated the existence of entangled states which do not violate any Bell-type inequality. The standard two-qubit Werner state is defined by

\[
\rho_Y^{(p)}(0) = p|Y\rangle\langle Y| + \frac{1-p}{4}I \otimes I
\]

being a mixture for \( p \in (0, 1) \) of the singlet state \(|Y\rangle = (|10\rangle - |01\rangle)/\sqrt{2} \) and the separable maximally mixed state, given by \( I \otimes I \), where \( I \) is the identity operator of a single qubit. Definition [11] is often generalized to include mixtures of any maximally entangled state (MES) instead of the singlet state only. So, e.g., one can analyze the Werner-like state defined by [6, 11, 8]

\[
\rho_X^{(p)}(0) = p|X\rangle\langle X| + \frac{1-p}{4}I \otimes I,
\]

as a convex combination of the Bell state \(|X\rangle = (|00\rangle + |11\rangle)/\sqrt{2} \) and \( I \otimes I \). The original Werner state [11], contrary to [2], is invariant if both qubits are subjected to same unitary transformation, say \( U \otimes U \). Nevertheless, for a given \( p \), both states [11] and [2] exhibit the same entanglement properties, thus [2] is also referred to as the Werner state [6, 11, 8]. In addition to the fact that the Werner states can be entangled without violating any Bell inequality for some values of parameter \( p \), they can still be used for quantum-information processing including teleportation [9, 10]. Moreover, the Werner states, given by [11] and [2], can be considered maximally entangled mixed states of two qubits [11, 7] in the sense that their degree of entanglement cannot be increased by any unitary operations, and they have the maximum degree of entanglement for a given linear entropy (and vice versa).

We will study the effects of a lossy environment, modelled by thermal reservoirs, on the Bell-inequality violation and on the entanglement of the initial Werner and Werner-like states in the quest for new states including those having different orderings induced by two entanglement measures: concurrence \( C \) and negativity \( N \) (defined in Sect. IV). The relativity of the entanglement measures was first observed by Eisert and Plenio [12]. They showed numerically, using Monte Carlo simulation, that the condition

\[
C(\rho_1) < C(\rho_2) ⇔ N(\rho_1) < N(\rho_2)
\]

can be violated by some two-qubit mixed states, although it is satisfied if \( \rho_1 \) and \( \rho_2 \) are the Werner states or pure states. Virmani and Plenio [13] demonstrated that all good asymptotic entanglement measures are either identical or impose different orderings of quantum states. The problem of relativity of the entanglement measures was also studied in Refs. [8, 14, 15, 16, 17]. Here, in particular, we present analytical examples of different orderings imposed by the concurrence and negativity for two-qubit states, which violate the Bell inequality to the same degree.

The Letter is organized as follows. In Sect. II, we discuss a dissipative model and give a general solution for two decaying qubits initially in the Werner states. A comparative study of the Bell-inequality violation and entanglement of various decaying states are given in Sects. III and IV, respectively. A final comparison and conclusions are given in Sect. V.

II. MODEL FOR LOSS MECHANISM

We analyze evolution of two initially correlated qubits subjected to dissipation modelled by their coupling to
thermal reservoirs (phonon baths) as described by the following Hamiltonian
\[ H = H_S + h \sum_{k,n} \Omega_n^{(k)} (b_n^{(k)})^\dagger b_n^{(k)} + h \sum_{k,n} [g_n^{(k)} a_k^{(k)} b_n^{(k)} + \text{h.c.}] \] (4)
which is the sum of Hamiltonians for the system, \( H_S \), reservoirs and the coupling between them, respectively. It is a prototype model, where qubits can be implemented in various ways, e.g., by single-cavity modes restricted in the Hilbert space spanned by the two lowest Fock states (see, e.g., [18]). In (4), \( a_k \) is the annihilation operator for the \( k \)th (\( k = 1, 2 \)) qubit at the frequency \( \omega_k \); \( n_k^{(k)} \) is the annihilation operator for the \( n \)th oscillator at the frequency \( \Omega_n^{(k)} \), and \( g_n^{(k)} \) are the coupling constants of the reservoir oscillators. We assume no direct interaction between the qubits, thus the system Hamiltonian is simply given by \( H_S = \hbar \sum_{k=1}^3 \omega_k a_k^{\dagger} a_k \).

The standard master equation for the model reads as
\[ \frac{\partial}{\partial t} \rho = \frac{-i}{\hbar} [H, \rho] + \sum_{k=1}^2 \gamma_k (\tilde{n}_k (2a_k^{\dagger} \rho a_k - a_k^{\dagger} a_k \rho - \rho a_k^{\dagger} a_k) + (\tilde{n}_k + 1) (2a_k^{\dagger} \rho a_k^{\dagger} - a_k^{\dagger} a_k \rho - \rho a_k^{\dagger} a_k)) \] (5)
where \( \rho \) is the reduced density operator for the qubits, \( \gamma_k \) is the damping constant and \( \tilde{n}_k \) is the mean number of thermal photons of the \( k \)th reservoir. The exact solution of (4) for arbitrary initial conditions and arbitrary-dimensional systems is well known. By confining our analysis to the initial qubit states coupled to the quiet reservoirs (\( \tilde{n}_1 = \tilde{n}_2 = 0 \)), the solution in the computational basis \( \{|00\rangle, |01\rangle, |10\rangle, |11\rangle\} \) in the interaction picture can compactly be given as
\[ \rho(t) = \begin{pmatrix}
  f_1 & f_2 & f_3 & f_4 \\
  f_5 & f_6 & f_7 & f_8 \\
  f_9 & f_{10} & f_{11} & f_{12} \\
  f_{13} & f_{14} & f_{15} & f_{16}
\end{pmatrix}
\] (6)
where the elements of the initial density matrix \( \rho(0) \) are denoted by \( \rho_{2i+k,2j+l} \equiv \langle i, k | \rho(0) | j, l \rangle \); \( g_k = \exp(-\gamma_k t) \) and
\[ f_k = h g_k \{ (1 - g_k) \rho_{3-3-k} + \rho_{60} \}, \]
\[ h_k = g_{3-k} \{ (1 - g_k) \rho_{33-k} + \rho_{66-k} \}, \]
\[ h = 1 - (h_1 + h_2 + g_1 \rho_{22}). \] (7)
We will apply solution (6) to analyze the effect of dissipation on the Bell-inequality violation and entanglement of the initial Werner states.

III. BELL-INEQUALITY VIOLATION

We will study violation of the Bell inequality due to Clauser, Horne, Shimony and Holt (CHSH) [2]. In a special case of two qubits in an arbitrary mixed state \( \rho \), one can apply an effective criterion for violating the Bell inequality:
\[ |\text{Tr}(\rho B_{\text{CHSH}})| \leq 2 \] (8)
where \( B_{\text{CHSH}} \) is the Bell operator given by
\[ B_{\text{CHSH}} = a \cdot \sigma \otimes (b + b') \cdot \sigma + a' \cdot \sigma \otimes (b - b') \cdot \sigma \] (9)
with its mean value maximized over unit vectors \( a, a', b, b' \in \mathbb{R}^3 \). Moreover, \( \sigma \) is the vector of the Pauli spin matrices \( \sigma_1, \sigma_2, \sigma_3 \), and scalar product \( a \cdot \sigma \) stands for \( \sum_j a_j \sigma_j \). By noting that any \( \rho \) can be represented in the Hilbert-Schmidt basis as
\[ \rho = \frac{1}{4} \left( I \otimes I + r \cdot \sigma \otimes I + I \otimes s \cdot \sigma + \sum_{n,m=1}^3 t_{nm} \sigma_n \otimes \sigma_m \right) \] (10)
proved that the maximum possible average value of the Bell operator in the state \( \rho \) is given by
\[ \max_{B_{\text{CHSH}}} \text{Tr}(\rho B_{\text{CHSH}}) = 2 \sqrt{M(\rho)} \] (11)
in terms of \( M(\rho) = \max_{j,k} \{ u_j + u_k \} \), where \( u_j \) (\( j = 1, 2, 3 \)) are the eigenvalues of the real symmetric matrix
\[ U = T_\rho^T T_\rho \; T_\rho \text{ is the real matrix formed by the coefficients } t_{nm} = \text{Tr}(\rho \sigma_n \otimes \sigma_m), \text{ and } T_\rho \text{ is the transposition of } T_\rho \].
Thus, the necessary and sufficient condition for violation of inequality (8) by the density matrix (10) and Bell operator (9) for some choice of \( a, a', b, b' \) reads as \( M(\rho) > 1 \). To quantify the degree of the Bell-inequality violation one can use \( M(\rho) \), \( \sqrt{M(\rho)} \) (see, e.g., [19, 21]), or \( \max \{ 0, M(\rho) - 1 \} \) (see, e.g., [22]). But we propose to use the following quantity
\[ B(\rho) = \sqrt{M(\rho) - 1} \] (12)
which has a useful property that for any two-qubit pure state it is equal to the entanglement measures such as concurrence and negativity, defined in the next section. As \( M(\rho) \leq 2 \), it holds \( B(\rho) \in (0, 1) \), where \( B(\rho) = 1 \) corresponds to the maximal violation of inequality (8) and \( B(\rho) = 0 \) for states admitting the local hidden variable model. The larger value of \( B(\rho) > 0 \) the greater violation of the Bell inequality. Thus, \( B(\rho) \) can be used to quantify the degree of the Bell-inequality violation (BIV), and for short it will be referred to as the \textit{BIV degree}.

The BIV degrees for the initial Werner states \( \rho_X^{(p)}(0) \) and \( \rho_Y^{(p)}(0) \) are the same and equal to
\[ B_X^{(p)}(0) = B_Y^{(p)}(0) = \max \{ 0, 2p^2 - 1 \}^{1/2} \] (13)
implies that the states violate the Bell inequality iff \( 1/\sqrt{2} < p \leq 1 \). By changing the parameter \( p \) into \( \phi = (1 - 3p)/2 \), (13) goes into another well-known form.
mixed state given by $I \otimes I$ as follows (0 ≤ $p \leq 1$):

$$\rho^p_Z(0) = p|Z\rangle\langle Z| + \frac{1-p}{4} I \otimes I$$  \hspace{1cm} (19)$$

for which the BIV degree is given by (13) as for the standard Werner state. For this and other reasons concerning the entanglement properties (see Sect. IV) being the same as for the state (11), we shall simply refer to (13) as the Werner state despite the fact that (13) is not $U \otimes U$ invariant. The thermal reservoirs cause the decay of $\rho^p_Z(0)$ as follows

$$\rho^p_Z(t) = \frac{1}{4} \begin{bmatrix} h' & p|g_1\sqrt{g_2}\rangle & p\sqrt{g_1 g_2} & -p\sqrt{g_1 g_2} \\ p|g_1\sqrt{g_2}\rangle & g_1(2-g_1) & -p\sqrt{g_1 g_2} & p\sqrt{g_1 g_2} \\ p\sqrt{g_1 g_2} & -p\sqrt{g_1 g_2} & g_1(2-g_1) & -p\sqrt{g_1 g_2} \\ -p\sqrt{g_1 g_2} & p\sqrt{g_1 g_2} & -p\sqrt{g_1 g_2} & g_1(2-g_1) \end{bmatrix} \tag{20}$$

where $h' = 4 + g_1 g_2 - 2(g_1 + g_2)$. The eigenvalues $u_k$ are 

$$\{p^2 g_1 g_2, \frac{1}{2}(v \pm \sqrt{v^2 - 4p^2 g_1 g_2})\}$$

implying the following decay of the BIV degree

$$B^p_Z(t) = \max(0, p^2 g_1 g_2 + \frac{1}{2}(v + \sqrt{v^2 - 4p^2 g_1 g_2} - 1)^{1/2}$$  \hspace{1cm} (21)$$

where $v = (1 - g_1)^2(1 - g_2)^2 + p^2 g_1 g_2 (g_1 + g_2)$. For more explicit comparison of expressions for $B^p_X(t)$ and $B^p_Y(t)$, we find their short-time approximations up to linear terms in $t$ for $p > 1/\sqrt{2}$ as follows:

$$\rho^p_Y(t) = \rho^p_X(t) = \max(0, Q - (\gamma_1 + \gamma_2)\frac{p^2 t}{Q} + O(t^2))$$  \hspace{1cm} (22)$$

$$B^p_Z(t) = \max(0, Q - [5(\gamma_1 + \gamma_2) - |\gamma_1 - \gamma_2|]\frac{p^2 t}{4Q} + O(t^2))$$  \hspace{1cm} (23)$$

where $Q = \sqrt{2p^2 - 1}$. By attentively comparing (22) and (24), we find that it holds

$$B^p_X(t) = B^p_Y(t) \geq B^p_Z(t)$$  \hspace{1cm} (24)$$

for any evolution times. In a special case of short times, this result immediately follows from (22) and (28). So, for both the qubits coupled to the reservoir(s) ($\gamma_1, \gamma_2 > 0$), the evolution of $B^p_Z(t)$ > 0 differs from that of $B^p_X(t)$, as shown, e.g., by solid and broken curves in Fig. 2 (a,b). However, by assuming that only one of the qubits is coupled to the reservoir, say $\gamma_1 \neq 0$ and $\gamma_2 = 0$, the BIV degree of $\rho^p_Z(t)$ decreases at the same rate as that of $\rho^p_X(t)$ and $\rho^p_Y(t)$ and all the three the BIV degrees are given by

$$B^p_X(\gamma_2 = 0, t) = B^p_Y(\gamma_2 = 0, t) = B^p_Z(\gamma_2 = 0, t)$$

$$= \max(0, 2p^2 g_1 - 1)^{1/2}$$  \hspace{1cm} (25)$$

which is a special case of (14) and (15). Clearly for $\gamma_2 = 0$, (26) goes over into (22) as expected. The decays of the BIV degrees for one of the damping constants equal to zero are presented graphically by solid curves in Fig. 4.
IV. ENTANGLEMENT

To study the entanglement, we apply the concurrence and negativity being related to the entanglement of formation and entanglement cost, respectively.

The entanglement of formation of a mixed state $\rho$ is the minimum mean entanglement of an ensemble of pure states $|\psi_i\rangle$ that represents $\rho$,

$$E_F(\rho) = \min_{\{p_i,|\psi_i\rangle\}} \sum_i p_i E(|\psi_i\rangle\langle\psi_i|)$$

where $\rho = \sum_i p_i |\psi_i\rangle\langle\psi_i|$ and $E(|\psi\rangle\langle\psi|)$ is the entropy of entanglement of pure state $|\psi\rangle$ defined by the von Neumann entropy. As shown by Wootters, the entanglement of formation for two qubits in an arbitrary mixed state $\rho$ can explicitly be given as

$$E_F(\rho) = H\left(\frac{1}{2}[1 + \sqrt{1 - C(\rho)^2}]\right)$$

where $H(x)$ is the binary entropy and $C(\rho)$ is the Wootters concurrence defined by

$$C(\rho) = \max\{0, 2 \max_i \lambda_i - \sum_{i=1}^4 \lambda_i\}$$

FIG. 1: Decays of different measures for a given initial state in each sub-figure: The Bell-inequality violation degree $B_\psi^{(p)}(t)$, concurrence $C_\psi^{(p)}(t)$ and negativity $N_\psi^{(p)}(t)$ for qubits initially in the Werner states $\rho_\psi^{(p)}(0)$, where $\psi = X, Y, Z$ and $p = 1$ (left panel) or $p = 0.8$ (right panel), coupled to the same reservoir with the damping constant $\gamma_1 = \gamma_2 = 0.1$.

FIG. 2: Decays of a given measure for different states in each sub-figure. Notation and parameters are the same as in figure 1.

FIG. 3: Negativities $\Delta N_\psi^{(p)}(t) = N_\psi^{(p)}(t) - N_\psi^{(p)}(0)$ ($\psi = X, Y, Z$) corresponding to those presented in Fig. 2(f) and Table I for the same $\gamma_1 = \gamma_2 = 0.1$ and $p = 0.8$.

FIG. 4: Same as in figure 1 but for one qubit coupled to the reservoir with the damping constant $\gamma_1 = 0.1$, and the second qubit undamped ($\gamma_2 = 0$).
where $\lambda_i$ are the square roots of the eigenvalues of the matrix $\rho (\sigma_y \otimes \sigma_y) \rho^* (\sigma_y \otimes \sigma_y)$, where $\sigma_y$ is the Pauli spin matrix and the asterisk denotes complex conjugation. $E_F(\rho)$ and $C(\rho)$ are monotonic functions of one another and both range from 0 (for a separable state) to 1 (for a maximally entangled state), so that “one can take the concurrence as a measure of entanglement in its own right” [24].

The negativity is another measure of bipartite entanglement being related to the Peres-Horodecki criterion [23, 26] and defined by [12, 27, 24]

$$N(\rho) = \max \{0, -2 \sum \mu_j \} \quad (29)$$

where $\rho = \rho_{AB}$ is the density matrix of two subsystems (say, $A$ and $B$ with $d_A$ and $d_B$ levels, respectively), and the sum is taken over the negative eigenvalues $\mu_j$ of the partial transpose $\rho^{TA}$ of $\rho$ with respect to one of subsystems (say $A$) in the basis $\{|0\rangle, |1\rangle, ... , |d_A\rangle\}$:

$$\rho^{TA} = \sum_{i,j=0}^{d_A-1} \sum_{k,l=0}^{d_B-1} |i,k\rangle \rho_{ijkl} |j,k\rangle \langle i,l| \quad (30)$$

For two-qubit ($d_A = d_B = 2$) states, the sum in (29) can be skipped as $\rho^{TA}$ has at most one negative eigenvalue [30]. The negativity, especially in low-dimensional systems (2 $\otimes$ 2 and 2 $\otimes$ 3), is a useful measure of entanglement satisfying the standard conditions [28, 24]. The negativity [29] ranges from 0 (for a separable state) to 1 (for a MES) similarly to the concurrence and the BIV degree. It is worth noting that the logarithmic negativity, $\log_2[N(\rho) + 1]$, has a simple operational interpretation as a measure of the entanglement cost for the exact preparation of a two-qubit state $\rho$ under quantum operations preserving the positivity of the partial transpose (PPT) [31, 32].

The concurrences and negativities for all the three initial Werner states $\rho_\psi^{(p)}(0)$ ($\psi = X, Y, Z$) are the same and equal to

$$C_\psi^{(p)}(0) = N_\psi^{(p)}(0) = \max \{0, \frac{1}{2} (3p - 1) \} \quad (31)$$

but different from their BIV degree $B_\psi^{(p)}(0)$, given by [13]. For the Bell states, all the entanglement measures and the BIV degree are equal to one. However, by decreasing parameter $p$, the BIV degree of the Werner states decreases faster than their entanglement. For example, for $p = 0.8$, the initial values of the concurrences and negativities are equal to 0.7 while the BIV degree is 0.529 as shown in the right panels of Figs. 1, 2, and 4. By comparing [13] and [33] it is seen that the Werner states are entangled iff $1/3 < p \leq 1$. Thus, the Werner states for $p \in (1/3, 1/\sqrt{2})$ are entangled although admitting a local hidden model, i.e., satisfying the Bell inequality [3].

Qubits initially in the Werner state $\rho_X^{(p)}(0)$ coupled to the thermal reservoirs exhibit dissipation described by [14]. We find with the help of the Wootters formula that the concurrence for $\rho_X^{(p)}(t)$ exhibits the following decay

$$C_X^{(p)}(t) = \max \{0, \frac{\sqrt{g_1 g_2}}{2} \left( 2p - \sqrt{(2 - gp_1)(2 - qg_2)} \right) \} \quad (32)$$

with $q = 1 + p$. While the negativity, according to Peres-Horodecki criterion applied for $\rho_X^{(p)}(t)$, decays as

$$N_X^{(p)}(t) = \max \{0, \frac{1}{2} [ -g_1 - g_2 + (1 + p) g_1 g_2 + \sqrt{(g_1 - g_2)^2 + 4p^2 g_1 g_2}] \}. \quad (33)$$

By assuming that both qubits are coupled to the same reservoir described the damping constant $\gamma = \gamma_1 = \gamma_2$, we observe that the concurrence and negativity are the same for all evolution times as described by

$$C_X^{(p)}(t) = N_X^{(p)}(t) = \max \{0, \frac{g}{2} [(1 + p) g - 2(1 - p)] \}, \quad (34)$$

where $g = \exp(-\gamma t)$, as clearly depicted in Fig. 1(a,b). In another special case, for the initial Bell states ($p = 1$), the solutions for the concurrence and negativity simplify to

$$C_X^{(1)}(t) = \sqrt{g_1 g_2} \left( 1 - \sqrt{1 - g_1}(1 - g_2) \right), \quad N_X^{(1)}(t) = g_1 g_2, \quad (35)$$

respectively. On the other hand, for qubits decaying from the initial Werner state $\rho_Y^{(p)}(0)$, as described by [16], the concurrence decays in time as

$$C_Y^{(p)}(t) = \max \{0, \frac{1}{2} \sqrt{g_1 g_2} (2p - \sqrt{1 - p}) \times \sqrt{(2 - g_1)(2 - g_2) - pg_1 g_2} \} \quad (36)$$

while the negativity vanishes as follows

$$N_Y^{(p)}(t) = \max \{0, \frac{1}{2} (-2 + g_1 + g_2 - (1 - p) g_1 g_2 + \sqrt{(2 - g_1 - g_2)^2 + 4p^2 g_1 g_2}] \}. \quad (37)$$

Note that decays of all the entanglement measures, similarly to the BIV degree, are independent of the sign in definitions of $|X\rangle$ and $|Y\rangle$. In a special case for qubits coupled to the same reservoir ($\gamma_1 = \gamma_2$), [30] and [31] simplify, respectively, to

$$C_Y^{(p)}(t) = \max \{0, g \left( p - \sqrt{r(1 - g) + \frac{1}{4} r^2 g^2} \right) \}, \quad (38)$$

$$N_Y^{(p)}(t) = \max \{0, \sqrt{(1 - g)^2 + p^2 g^2 - \frac{1}{4} r g^2 - (1 - g)} \}$$

with $r = 1 - p$. In another special case for the initial Bell state ($p = 1$), the entanglement measures [30] and [37] reduce to

$$C_Y^{(1)}(t) = \sqrt{g_1 g_2}, \quad N_Y^{(1)}(t) = \frac{1}{2} \left( \sqrt{(2 - g_1 - g_2)^2 + 4g_1 g_2 + g_1 + g_2 - 2} \right),$$

\[\text{[14]}\]
respectively. It is worth mentioning that, in contrast to $C_X^{(p)}(t) = N_X^{(p)}(t)$ for $\gamma_1 = \gamma_2$, the evolutions $C_Y^{(p)}(t)$ and $N_Y^{(p)}(t)$ are different. Finally, let us briefly discuss the effect of dissipation of the initial Werner state $\rho_W^{(p)}(0)$, described by (20), on the entangled measures. The general analytical formulas for the $p$-dependent concurrence and negativity are quite lengthy thus are not presented here explicitly although were used for plotting the corresponding curves in Figs. 1(e,f), 2(e,f) and 3. However, in a special case for the initial Bell-like state ($p = 1$) the decays of the entanglement measures are simply given by:

$$C_Y^{(1)}(t) = \sqrt{g_1 g_2} \left( \frac{1}{2} \sqrt{(1 - g_1)(1 - g_2)} \right),$$

$$N_Y^{(1)}(t) = \frac{1}{2} \sqrt{g_1 g_2 (5 + g_1 g_2 - 2G)} + 4(1 - G)^2 + G - 1$$

with $G = (g_1 + g_2)/2$. By assuming the same damping constants $\gamma_1 = \gamma_2$, e.g., the concurrence formula reduces to $C_Y^{(1)}(t) = g(1 + g)/2$. A graphical comparison of the decays of all the measures is shown in Fig. 2 and of the negativities in Fig. 3 and Table I for $\gamma_1 = \gamma_2 = 0.1$. Since the differences between the negativities $N_Y^{(p)}(t)$ are not clear enough in Fig. 2(f), the curves were redrawn in Fig. 3 for the rescaled negativities $\Delta N_Y^{(p)}(t) \equiv N_Y^{(p)}(t) - N_Y^{(0)}(t)$ with $\psi = X, Y, Z$.

For a closer look at the inequalities (22) and (43) for $\gamma_1, \gamma_2 > 0$, we can conclude that all the three negativities evolve in a more similar way (precisely they are the same up to linear terms in time) in comparison to more distinct evolutions of the corresponding concurrences.

By comparing the series expansions (42) and (43) for $\gamma_1, \gamma_2 > 0$, we can conclude that all the three negativities evolve in a more similar way (precisely they are the same up to linear terms in time) in comparison to more distinct evolutions of the corresponding concurrences. Also by analyzing (22) and (43) for $p = 1$, one observes that the negativities $N_X^{(p)}(t)$ and the BIV degrees $B_X^{(1)}(t)$ decay in the same manner up to linear terms in time for arbitrary values of $\gamma_1$ and $\gamma_2$. Other similarities of the decays of the entanglement and/or the BIV degree can be found for some special choices of the damping constants. In particular, (44) is valid for $\gamma_1 = \gamma_2$. In another special case of only one of the qubits coupled to the reservoir, e.g., $\gamma_1 \neq 0$ and $\gamma_2 = 0$, the BIV degrees of all the three states decrease, as given by (25), but also the entanglement measures decrease at the same rate as expressed by their concurrence

$$C_X^{(p)}(\gamma_2 = 0, t) = C_Y^{(p)}(\gamma_2 = 0, t) = C_Z^{(p)}(\gamma_2 = 0, t) = \max\{0, 1/2 \sqrt{g_1} \left(2p - \sqrt{(1-p)(1-p)}\right)\}$$

and negativity

$$N_X^{(p)}(\gamma_2 = 0, t) = N_Y^{(p)}(\gamma_2 = 0, t) = N_Z^{(p)}(\gamma_2 = 0, t) = \max\{0, 1/2 \left(pg_1 + \sqrt{(1-g_1)^2 + 4p^2g_1 - 1}\right)\}.$$

By restricting to the case of the initial MESSs ($p = 1$), the above equations reduce to ($\psi = X, Y, Z$):

$$C_Y^{(1)}(\gamma_2 = 0, t) = \sqrt{g_1},$$

$$N_Y^{(1)}(\gamma_2 = 0, t) = g_1.$$

These conclusions are confirmed numerically on the examples of $\gamma_1 = 0.1$, $p = 0.8$ and $p = 1$ as shown in Fig. 4.

V. CONCLUSIONS

We have analyzed quantum-information properties of two decaying optical qubits prepared initially in Werner or Werner-like states and coupled to thermal reservoirs within the master equation approach. We have studied in detail a degree of violation of the Bell inequality due to Clauser, Horne, Shimony and Holt (2) by applying a parameter $B$ related to the maximum possible mean
TABLE I: Comparison of the negativities for the three initial Werner states for \( p = 0.8, \gamma_1 = \gamma_2 = 0.1 \) as in Figs. 2(t) and 3. The characteristic evolution times are \( t_1 \approx 7.4745, t_2 \approx 9.1613, t_3 \approx 9.5209 \). The corresponding inequalities for the BIV degrees are \( B^{(p)}_X(t) = B^{(p)}_Y(t) \geq B^{(p)}_B(t) \), and for the concurrences are \( C^{(p)}_X(t) \geq C^{(p)}_Y(t) \geq C^{(p)}_B(t) \).

| time | negativities |
|------|--------------|
| \( t \in (0, t_1) \) | \( N^{(p)}_X(t) > N^{(p)}_Y(t) > N^{(p)}_B(t) \) |
| \( t = t_2 \) | \( N^{(p)}_X(t) > N^{(p)}_Y(t) > N^{(p)}_B(t) \) |
| \( t \in (t_1, t_2) \) | \( N^{(p)}_X(t) > N^{(p)}_Y(t) > N^{(p)}_B(t) \) |
| \( t = t_3 \) | \( N^{(p)}_X(t) = N^{(p)}_Y(t) > N^{(p)}_B(t) \) |
| \( t \in (t_2, t_3) \) | \( N^{(p)}_X(t) > N^{(p)}_Y(t) > N^{(p)}_B(t) \) |
| \( t = t_3 \) | \( N^{(p)}_X(t) > N^{(p)}_Y(t) = N^{(p)}_B(t) \) |
| \( t \in (t_3, 100) \) | \( N^{(p)}_X(t) > N^{(p)}_Y(t) > N^{(p)}_B(t) \) |

value of the Bell operator in a given state according to the Horodecki criterion \[19\]. On the other hand, the degree of the entanglement was expressed by the Wooters concurrence \[24\], as a measure of the entanglement of formation, and by the negativity \( N \) based on the Peres-Horodecki criterion \[25,26\] and related to the PPT-entanglement cost \[31\]. We have observed, as manifestations of the symmetry of our particular decoherence mechanism, the following properties of the decaying Werner states in relation to the Bell-inequality violation degree \( B \) and the entanglement measures \( C \) and \( N \): If only one qubit is coupled to the thermal reservoir than those decays are independent of the initial Werner or Werner-like state for a given \( p \). However, if both qubits are coupled to the reservoir(s) then the decays of \( C \) and \( N \), and in some cases \( B \), depend on the initial Werner or Werner-like state. By analyzing these decays, we have found states (say \( \rho \) and \( \sigma \)) of two qubits exhibiting the same degree the Bell-inequality violation, \( B_\rho = B_\sigma \), but different entanglement measures in such a way that the concurrence \( C_\rho \) is smaller than \( C_\sigma \), while the negativity \( N_\rho \) is greater than \( N_\sigma \). We have also found other states \( \rho \) and \( \sigma \), for which either (i) \( B_\rho = B_\sigma, C_\rho < C_\sigma \) and \( N_\rho > N_\sigma \), or (ii) \( B_\rho = B_\sigma, N_\rho = N_\sigma \) and \( C_\rho < C_\sigma \). Thus, the analysis of the decaying Werner states shows clearly the relativity of two-qubit entanglement measures.

Acknowledgments

The author thanks Jens Eisert, Andrzej Grudka, Paweł Horodecki, Wiesław Leóñski, and Ryszard Tanaś for stimulating discussions.
