Characterization of glycosphingolipids from gastrointestinal stromal tumours

Licínia Santos1, Chunsheng Jin1, Tatána Gazárková1, Anders Thornell2,3, Olov Norlén4, Karin Säljö3,5 & Susann Teneberg1,5*

Gastrointestinal stromal tumours (GISTs) are the major nonepithelial neoplasms of the human gastrointestinal tract with a worldwide incidence between 11 and 15 per million cases annually. In this study the acid and non-acid glycosphingolipids of three GISTs were characterized using a combination of thin-layer chromatography, chemical staining, binding of carbohydrate recognizing ligands, and mass spectrometry. In the non-acid glycosphingolipid fractions of the tumors globotetraosylceramide, neolactotetraosylceramide, and glycosphingolipids with terminal blood group A, B, H, Le\(^x\), Le\(^a\), Ley and Le\(^b\) determinants were found. The relative amounts of these non-acid compounds were different in the three tumour samples. The acid glycosphingolipid fractions had sulfatide, and the gangliosides GM3, GD3, GM1, Neu5Acα3neolactotetraosylceramide, GD1α, GT1b and GQ1b. In summary, we have characterized the glycosphingolipids of GISTs and found that the pattern differs in tumours from different individuals. This detailed characterization of glycosphingolipid composition of GISTs could contribute to recognition of new molecular targets for GIST treatment and sub-classification.

Abbreviations

GIST  Gastrointestinal stromal tumours
LC-ESI/MS  Liquid chromatography electrospray ionization mass spectrometry

The most common mesenchymal neoplasms of the human gastrointestinal tract are gastrointestinal stromal tumours (GISTs). These tumours are rare, and the incidence is between 11 and 15 cases/million/year worldwide. The majority of the GISTs (60%) are located in the stomach, whereas 30% are in the jejunum or ileum, 5% in the duodenum and 4% in the colorectum1,2. GISTs arise from the interstitial cells of Cajal, also called the pacemaker cells for peristaltic contraction1. These cells are found in the muscularis propria and around the myenteric plexus along the gastrointestinal tract, and they have immunophenotypic and ultrastructural characteristics of both neural and smooth muscle elements1. Around 80% of GISTs have a mutation in the KIT tyrosine kinase gene, and just over 5% have a mutation in the KIT-homologous tyrosine kinase platelet-derived growth factor receptor alpha (PDGFRα) gene3. Hence, about 10% to 15% of GISTs are negative for KIT and PDGFRα mutations (termed “wild-type GISTs”)4. The type of mutation has prognostic importance and correlates with response to targeted drugs such as imatinib3,5–7.

Altered glycosylation is a common feature of cancer cells, and an increase in fucosylation, sialylation, and branching of glycans, is often found8–10. These changes may affect any type of glycoconjugate, such as N-glycans and O-glycans on glycoproteins, glycosphingolipids or proteoglycans. Certain glycan structures are well-known markers for tumour prognosis, and some serum tumour biomarkers presently used in clinical practice are serum glycoproteins, such as CEA, CA19-9, and CA-125 for colon, pancreatic, and ovarian cancer, respectively11–13. Thus, studies of aberrations in glycan structures can be used as targets to improve existing cancer biomarkers.

https://doi.org/10.1038/s41598-020-76104-3
The present study is the first investigation of glycosphingolipids in GISTs. Acid and non-acid glycosphingolipids were isolated from three gastric tumours, and the glycosphingolipid fractions obtained were characterized by mass spectrometry and by binding of a battery of carbohydrate recognizing ligands. Sulfatide, and the gangliosides GM3, GD3, GM1, Neu5Acα3neolactotetraosylceramide, GD1a, GT1b and GQ1b were found in the acid glycosphingolipid fractions. The non-acid glycosphingolipid fractions of the tumours had globotetraosylceramide, neolactotetraosylceramide, and glycosphingolipids with terminal blood group A, B, H, Leª, Leô, Leª and Leô determinants. The relative amounts of the non-acid compounds were different in the three tumour samples. This characterization of the glycosphingolipid patterns in GISTs might contribute to the development of new prognosis markers and therapeutic approaches.

**Results**

**Isolation of glycosphingolipids.** Three gastric GIST tumours (denoted GIST I, GIST II and GIST III) were collected. GIST I was from a blood group A individual, GIST II from a blood group AB individual, and GIST III from a blood group O individual (Table 1). Total acid and non-acid glycosphingolipid fractions were isolated from the three tumours by standard procedures. The amounts of acid and non-acid glycosphingolipids obtained are given in Table 1. The total acid fractions isolated from GIST I and II are shown in Fig. 1A,B, lanes 4 and 5. Both fractions had a major band co-migrating with reference GM3 ganglioside (lane 1), and also had a number of more slow-migrating bands.

The total non-acid glycosphingolipid fractions had a number of compounds migrating as mono-, di-, tri and tetraglycosylceramides, and also some minor slow-migrating compounds (exemplified by GIST I and II in Fig. 2A, lanes 3 and 4).

**Characterization of total acid GIST glycosphingolipids.** LC-ESI/MS. The native total acid glycosphingolipids fractions from GIST I and II were analyzed by LC-ESI/MS (exemplified in Fig. 3). In both cases the major molecular ions were from the GM3 ganglioside with d18:1–16:0 ceramide (m/z 1151) and d18:1–24:1 ceramide (m/z 1261). In the case of GIST II there were also molecular ions of the GD3 ganglioside with d18:1–24:1 ceramide (m/z 776) and the GD1a ganglioside with d18:1–24:1 ceramide (m/z 959). A minor ion at m/z 794 was found by search for molecular ions of sulfatide, and MS² of this ion gave a characteristic sulfatide spectrum (Supplemental Figure S1).

**Chromatogram binding assays.** The binding of a number of carbohydrate binding ligands to the total acid glycosphingolipids fractions from GIST I and II were next examined (Fig. 1). Here the monoclonal antibodies directed against the Neu5Acα3Galβ4GlcNAc sequence recognized several slow-migrating compounds in the acid fractions from the two GISTs (Fig. 1C, lanes 4 and 5), indicating the presence of complex gangliosides with neolactotetraosylceramide, and glycosphingolipids with terminal blood group A, B, H, Leª, Leô, Leª and Leô determinants. Presence of the GM1 ganglioside was indicated by the binding of cholera toxin B-subunits (Fig. 1D, lanes 4 and 5). The monoclonal antibodies directed against the GD1a ganglioside also bound to the acid fractions from the two GIST tumours (Fig. 1E, lanes 4 and 5), whereas there was no binding of anti-GD3 antibodies or antibodies directed against the Neu5Acα6Galβ4GlcNAc sequence (not shown).

**Separation of the acid glycosphingolipids of GIST II.** Since very little information was obtained from these LC-ESI/MS analyses the total acid glycosphingolipid fraction of GIST II was further separated on an ion-exchange column eluted with increasing volumes of methanol in chloroform. This gave one fraction containing slow-migrating compounds (18 mg), and this fraction was further separated into subfractions that were pooled.

**LC-ESI/MS of fractions A1–A5.** LC-ESI/MS of fraction A-1 gave two major molecular ions at m/z 1151 and m/z 1263. MS² of these ions identified the GM3 ganglioside with d18:1–16:0 and d18:1–24:0 ceramides, respectively (data not shown).

A number of doubly charged ([M–2H+]+) molecular ions were obtained by LC-ESI/MS of fraction A-2. MS² identified the major molecular ion as the GD1a ganglioside with d18:1–16:0 ceramide (m/z 903), d18:1–22:0 ceramide (m/z 946), and d18:1–24:0 ceramide (m/z 960) (Fig. 4C). The presence of the GD1a ganglioside in fraction A-2 was in line with the binding of anti-GD1a antibodies to this fraction (Fig. 4B, lane 3).

There were also [M–2H+]+ ions of the GD3 ganglioside (m/z 721, m/z 763 and m/z 777), and of Neu5Acα3neolactotetraosylceramide or the GM1 ganglioside (m/z 814).
The base peak chromatogram obtained from fraction A-3 was weak and only had one \([M - 2H^+]^{2-}\) ion at \(m/z\) 777 corresponding to the GD3 ganglioside and one \([M - 2H^+]^{2-}\) ion at \(m/z\) 960 corresponding to the GD1a ganglioside, both with d18:1–24:0 ceramide (data not shown).

\([M - 2H^+]^{2-}\) ions at \(m/z\) 777 and at \(m/z\) 960 corresponding to the GD3 and GD1a gangliosides were also found by LC-ESI/MS of fraction A-4 (Fig. 4D). Here the major compound gave a \([M - 2H^+]^{2-}\) ion at \(m/z\) 1105.5. MS² of \(m/z\) 1105.5 demonstrated a ganglioside with three Neu5Ac, three Hex and one HexNAc and d18:1–24:0 ceramide (Fig. 5A). The ion at \(m/z\) 581 demonstrated a Neu5Ac–Neu5Ac sequence, while the ions at \(m/z\) 1920,
m/z 1629 and m/z 1338 were due to loss of one, two and three Neu5Ac from the molecular ion. MS² of m/z 960 also gave ions at m/z 1629 and m/z 1338 caused by loss of one and two Neu5Ac, and also an ion at m/z 972 due to loss of a Hex and a HexNAc (Fig. 5B). Taken together this demonstrated a GT1b ganglioside with d18:1–24:0 ceramide (Fig. 5C). In the same manner the GT1b ganglioside with d18:1–16:0 ceramide was identified by MS² and MS³ of the [M − 2H⁺]²⁻ ion at m/z 1049.5, and the GT1b ganglioside with d18:1–22:0 ceramide by MS² and MS³ of the [M − 2H⁺]²⁻ ion at m/z 1091.

Figure 2. Thin-layer chromatography of the non-acid glycosphingolipids of GIST tumors, and binding of carbohydrate recognizing ligands. Thin-layer chromatogram after detection with anisaldehyde (A), and autoradiograms obtained by binding of, the Galβ4GlcNAc-/Fucα2Galβ4GlcNAc-binding lectin from E. cristagalli (B), and monoclonal antibodies directed against the blood group A determinant (C). The lanes were: lane 1, reference total non-acid glycosphingolipids of human blood group AB erythrocytes, 40 µg; lane 2, reference calf brain gangliosides, 40 µg; lane 3, total non-acid glycosphingolipids of GIST I, 40 µg; lane 4, total non-acid glycosphingolipids of GIST II, 40 µg.

Figure 3. Base peak chromatogram from LC-ESI/MS of the total acid glycosphingolipid fraction from GIST II. The identification of glycosphingolipids was based on their retention times, determined molecular masses and subsequent MS² sequencing. The data were processed using the Xcalibur software (version 2.0.7, Thermo Scientific, www.thermoscientific.com). The glycosphingolipids identified in the chromatograms were: Sulfatide, SO₃-3Galβ1Cer; Neu5Ac-GM3, Neu5Aca3Galβ4Glcβ1Cer; Neu5Ac-GD3, Neu5Aca8Neu5Aca3Galβ4Glcβ1Cer; Neu5Aca-GD1a, Neu5Aca3Galβ3GalNAcβ4(Neu5Aca3)Galβ4Glcβ1Cer. In the shorthand nomenclature for fatty acids and bases, the number before the colon refers to the carbon chain length and the number after the colon gives the total number of double bonds in the molecule. Fatty acids with a 2-hydroxy group are denoted by the prefix h before the abbreviation e.g. h16:0. For long chain bases, S designates sphingosine (d18:1).
Figure 4. Characterization of the acid glycosphingolipid subfractions isolated from GIST II. Thin-layer chromatogram after detection with anisaldehyde (A), and autoradiogram obtained by binding of monoclonal antibodies directed against the ganglioside GD1a (B). The lanes were: lane 1, reference calf brain gangliosides, 40 µg; lanes 2–6, acid GIST fractions A-1–A-5, 20 µg/lane. (C) Molecular ion profile from LC-ESI/MS of fraction A-2. (D) Molecular ion profile from LC-ESI/MS of fraction A-4. The identification of glycosphingolipids was based on their retention times, determined molecular masses and subsequent MS² sequencing. The data were processed using the Xcalibur software (version 2.0.7, Thermo Scientific, www.thermofisher.com). In the shorthand nomenclature for fatty acids and bases, the number before the colon refers to the carbon chain length and the number after the colon gives the total number of double bonds in the molecule. For long chain bases, S designates sphingosine (d18:1). * marks non-glycosphingolipid contaminants.
LC-ESI/MS of fraction A-5 gave a major [M − 2H+]2− ion at m/z 1049.5, and the GT1b ganglioside with d18:1–16:0 ceramide was again identified by MS2 and MS3 of this ion (Fig. 6A,B,E). The base peak chromatogram also had a [M − 2H+]2− ion at m/z 1195 ([M − H+]− ion at m/z 2390) corresponding to a ganglioside with four Neu5Ac, three Hex and one HexNAc and d18:1–24:0 ceramide. By MS2 and MS3 of the ion at m/z 1195 the GQ1b ganglioside with d18:1–24:0 ceramide was tentatively characterized (Fig. 6C,D,E).

The gangliosides characterized in the acid glycosphingolipid fraction of GIST II are summarized in Table 2.

Characterization of total non-acid GIST glycosphingolipids. LC-ESI/MS of native glycosphingolipids. To get an overview of the ceramide composition the native non-acid glycosphingolipid fractions of GIST I and GIST II were first analyzed by LC-ESI/MS using a polyamine column (exemplified in Fig. 7). Thereby dihexosylceramide, trihexosylceramide, and a tetraosylceramide with one HexNAc and three Hex, all with mainly sphingosine and non-hydroxy fatty acids with 16 and 24 carbon atoms were identified.

LC-ESI/MS of glycosphingolipid-derived oligosaccharides. Thereafter the non-acid glycosphingolipid fractions were hydrolyzed with endoglycoceramidase II from Rhodococcus sp., and the oligosaccharides thereby obtained were characterized by LC-ESI/MS using a graphitized carbon column. By LC-ESI/MS of oligosaccharides on graphitized carbon columns a resolution of isomeric oligosaccharides is obtained, and by MS2 a series of C-type ions is obtained which gives the carbohydrate sequence. Furthermore, the MS2 spectra of oligosaccharides with a Hex or HexNAc substituted at C-4 have diagnostic cross-ring 3,2-A-type fragment ions which allow identification of linkage positions. Thus, MS2 spectra of oligosaccharides with globo (Galα4Gal) or type 2 (Galβ4GlcNAc) core structures have such 3,2-A-type fragment ions, but not the spectra obtained from oligosaccharides with isoglobo (Galα3Gal) or type 1 (Galβ3GlcNAc) core chains.

The base peak chromatogram from LC-ESI/MS of the oligosaccharides obtained from GIST I (Fig. 8A) had a number of molecular ions corresponding to tetrasaccharides (detected as [M − H+]− ions at m/z 706) to
Figure 6. LC-ESI/MS of fraction A-5. (A) MS² of the [M − 2H⁺]²⁻ ion at m/z 1050. (B) MS³ of the ion at m/z 904. (C) MS² of the [M − 2H⁺]²⁻ ion at m/z 1195. (D) MS³ of the ion at m/z 1808. (E) The interpretation formulas show the deduced ganglioside structures. The data were processed using the Xcalibur software (version 2.0.7, Thermo Scientific, www.thermofisher.com).

Table 2. Gangliosides of GIST II identified by LC-ESI/MS.

| Trivial name | Structure |
|--------------|-----------|
| GM3          | Neu5Acα3Galβ4Glcβ1Cer |
| GM1          | Galβ3GalNAcβ4(Neu5Acα3)Galβ4Glcβ1Cer |
| Neu5Acα3Neolacto4 | Neu5Acα3Galβ4GlcNAcβ3Galβ4Glcβ1Cer |
| GD3          | Neu5Acα8Neu5Acα3Galβ4Glcβ1Cer |
| GD1a         | Neu5Acα3Galβ3GalNAcβ4(Neu5Acα3)Galβ4Glcβ1Cer |
| GT1b         | Neu5Acα3Galβ3GalNAcβ4(Neu5Acα8Neu5Acα3)Galβ4Glcβ1Cer |
| GQ1b         | Neu5Acα8Neu5Acα3Galβ3GalNAcβ4(Neu5Acα8Neu5Acα3)Galβ4Glcβ1Cer |
heptasaccharides (detected as [M – H+]− ions at m/z 1201). The predominant molecular ion was found at m/z 706 at retention time 24.7 min. These molecular ions were subjected to MS2 (Fig. 8 and Supplementary Fig. S2).

A prominent 0,2A2 fragment ion at m/z 281 demonstrating a terminal Hex-HexNAc sequence with a 4-substituted HexNAc, i.e. a type 2 core chain (Galβ4GlcNAc) was present in the MS2 spectrum of the ion at m/z 706 (Fig. 8B). There was also a C2 ion at m/z 382 and a C3 ion at m/z 544, and taken together this demonstrated a neolacto tetrasaccharide (Galβ4GlcNAcβ3Galβ4Glc).

The MS2 spectrum of the ion at m/z 852 at retention time 19.5 min (Fig. 8C) had a fragment ion at m/z 364. This type of fragment ion is caused by a double glycosidic cleavage of the 3-linked branch at C1 and Z1, and is diagnostic for an internal 4-linked GlcNAc with a Fuc at 3-position17. The MS2 spectrum also had a C2 ion at m/z 528 and a C3 ion at m/z 690. Taken together these spectral features identified a Lex pentasaccharide (Galβ4(Fucα3)GlcNAcβ3Galβ4Glc).

MS2 of the molecular ion at m/z 852 eluting at 26.0 min (Fig. 8D) identified a Fuc-Hex-HexNAc-Hex-Hex pentasaccharide. This was conluded from the series of C-type fragment ions (C2 at m/z 325, C3 at m/z 528, and C4 at m/z 690). 4-substitution of the HexNAc, i.e. a type 2 core chain (Galβ4GlcNAc) was indicated by the 0,2A3-H2O fragment ion at m/z 409 and the 0,2A3 fragment ion at m/z 427. Taken together this identified a H type 2 pentasaccharide (Fucα2Galβ4GlcNAcβ3Galβ4Glc).

A pentasaccharide with HexNAc-Hex-HexNAc-Hex-Hex sequence was identified by the C-type fragment ion series (C2 at m/z 382, C3 at m/z 585, and C4 at m/z 747) obtained by MS2 of the molecular ion at m/z 909 (Fig. 8E). Here the 0,2A2-H2O fragment ion at m/z 409 and the 0,2A2 fragment ion at m/z 427. Taken together this identified a H type 2 pentasaccharide (Fucα2Galβ4GlcNAcβ3Galβ4Glc).

Figure 7. Molecular ion profile from LC-ESI/MS of the total non-acid glycosphingolipid fraction from GIST II. The identification of glycosphingolipids was based on their retention times, determined molecular masses and subsequent MS2 sequencing. The data were processed using the Xcalibur software (version 2.0.7, Thermo Scientific, www.thermo.com). In the shorthand nomenclature for fatty acids and bases, the number before the colon refers to the carbon chain length and the number after the colon gives the total number of double bonds in the molecule. Fatty acids with a 2-hydroxy group are denoted by the prefix h before the abbreviation e.g. h16:0. For long chain bases, S designates sphingosine (d18:1) and P phytosphingosine (t18:0). *marks a non-ganglioside contaminant.

A neolacto hexasaccharide (Galβ4GlcNAcβ3Galβ4GlcNAcβ3Galβ4Glc) was characterized by MS2 of the ion at m/z 1071 (Fig. 8H). This was deduced from the C-type fragment ion series (C2 at m/z 382, C3 at m/z 544, C4 at m/z 747, and C5 at m/z 909), demonstrating a Hex-HexNAc-Hex-HexNAc-Hex-Hex carbohydrate sequence, along with the 0,2A2 fragment ion at m/z 646, which demonstrated 4-substitution of the innermost HexNAc.
MS² of the molecular ion at m/z 1201 (Fig. 8I) gave a spectrum that was very similar to the MS² spectrum obtained from reference blood group type 1/ALε⁵ heptasaccharide. The series of C-type fragment ions (C₁, at m/z 528, C₂, at m/z 877, and C₃, at m/z 1039) demonstrated a HexNAc-(Fuc-)Hex-(Fuc-)HexNAc-Hex-Hex sequence. The spectrum also had an ion at m/z 656, caused by a double glycosidic cleavage of the 3-linked branch at C₃, and Z₄α, and thus signifying an internal 3-linked GlcNAc substituted with a Fuc at C-4. Thus, this demonstrated a blood group A type 1/ALε⁵ heptasaccharide (GalNAca3(Fucα2)Galβ3(Fucα4)GlcNAcβ3Galβ4Glc).

The series of B-type and C-type fragment ions (C₁, at m/z 528, B₁, at m/z 875, B₂, at m/z 1078, and C₃, at m/z 1258) obtained by MS² of the ion at m/z 1420 (Fig. 8I) indicated a HexNAc-(Fuc)-HexNAc-HexNAc-Hex-Hex sequence. The 0,2A₃ fragment ion at m/z 630, and the 0,2A₅ fragment ion at m/z 995, demonstrated that the two internal HexNAcs were substituted at C4. Taken together this indicated a blood group A type 2 octasaccharide (GalNAca3(Fucα2)Galβ4GlcNAcβ3Galβ4Glc).

Finally, the MS² spectrum of the ion at m/z 1436 (Fig. 8K) gave a tentative identification of a neolacto octasaccharide (Galβ4GlcNAcβ3Galβ4GlcNAcβ3Galβ4GlcNAcβ3Galβ4Glc). Here the lower mass region of the spectrum was weak, but had similarities with the spectrum in Fig. 8H. Thus, the C₁ ion at m/z 747, the C₂ ion at m/z 909 and the C₃ ion at m/z 1112, allowed a tentative identification of an octasaccharide with Hex-HexNAc-HexNAc-Hex-HexNAc-Hex-Hex sequence, and 4-substitution of the two innermost HexNAcs was demonstrated by with the 0,2A₃ fragment ion at m/z 646 and the 0,2A₅ fragment ion at m/z 1011.

Thus, the oligosaccharide derived from the non-acid glycosphingolipids of GIST I had mainly type 2 core chains, with neolactotetraose (Galβ4GlcNAcβ3Galβ4Glc) as the predominant compound. There were also several other minor compounds with neolacto core chain as the Le₄ and x₂ pentasaccharides, the blood group A type 2 hexa- and octasaccharides, and neolacto hexa- and octasaccharides. Minor oligosaccharides with type 1 core chains (Le₄ hexasaccharide, and blood A type 1 heptasaccharide) were also present.

The base peak chromatogram from LC-ESI/MS of the oligosaccharides obtained from GIST II also had molecular ions ranging from m/z 706 to m/z 1201 (Supplementary Fig. S3A). Here MS² showed that the GIST II oligosaccharides had a globo tetrasaccharide in addition to the neolactotetrasaccharide, a Le⁵ pentasaccharide in addition to the Le⁴ hexasaccharide, a Le⁴ hexasaccharide in addition to the Le⁵ hexasaccharide (exemplified in Supplementary Fig. S3B-G), and a blood group B heptasaccharide in addition to the blood group A heptasaccharide (see further below). The x₂ and blood group H type 2 pentasaccharides, the blood group A type 2 hexa-saccharide, and the neolacto and blood group A type 2 octasaccharides were not detected in the GIST II sample. A globo trisaccharide, globo and neolacto tetrasaccharides, Le₄, x₂ and blood group H type 2 pentasaccharides, and Le⁵ and Le⁴ hexaxaccharides were characterized by LC-ESI/MS of the oligosaccharides derived from GIST III (data not shown). The glycosphingolipid-derived oligosaccharides from GIST I, GIST II and GIST III characterized by LC-ESI/MS are summarized in Table 3.

Chromatogram binding assays. In order to extend the structural information obtained by mass spectrometry the binding of carbohydrate binding ligands to the non-acid glycosphingolipid fractions of GISTI and GISTII was next examined in a chromatogram binding assay. Thereby, a distinct interaction of the Galβ4GlcNAc binding lectin from E. cristagalli was obtained, confirming the presence of neolactotetraosylceramide in both tumors (Fig. 2B, lanes 3 and 4). The lectin binding to the glycosphingolipids of GIST I (lane 3) was more distinct than the binding to the glycosphingolipids of GIST II (lane 4), in line with the higher amount of neolactotetraosylceramide in GIST I. The presence of glycosphingolipids with blood group A determinants in the GISTs was confirmed by the binding of anti-A antibodies (Fig. 2C, lanes 3 and 4).

Separation of the non-acid glycosphingolipids of GIST II. After these studies the remaining material in the non-acid glycosphingolipid fraction from GIST II was separated on latexbeads columns, in order to enrich the slow-migrating glycosphingolipids. After pooling three glycosphingolipid-containing fractions were obtained (denoted fractions N-I to N-III). The three fractions were digested by Rhodococcus endoglycoceramidase and the oligosaccharides obtained were analyzed by LC-ESI/MS. Thereby globotetra, neolactotetra, Le⁵, x₂, and Le⁴ hexasaccharides were identified in fraction N-I, whereas Le⁵ hexa and Le⁴ hex saccharides were characterized in fraction N-II (data not shown).

The base peak chromatogram from LC-ESI/MS of the oligosaccharides from fraction N-III (Fig. 9A) had two [M – H⁺]⁻ ions at m/z 1160, eluting at 12.8 min and 14.3 min, respectively. There were also two [M – H⁺]⁻ ions at m/z 1201, one major eluting at 14.7 min, and one minor eluting at 20.2 min. In addition, there were two [M – H⁺]⁻ ions at m/z 998, which were identified as Le⁴ and Le⁵ hexa saccharides by MS² (data not shown).

A blood group B type 2/ALε⁵ heptasaccharide (Galα3(Fucα2)Galβ4(Fucα3)GlcNAcβ3Galβ4Glc) was demonstrated by MS² of the [M – H⁺]⁻ ion at m/z 1160 at retention time 12.8 min (Fig. 9B,F). The series of C-type fragment ions (C₁, at m/z 487, C₂, at m/z 836, and C₃, at m/z 998) established a Hex-(Fuc-)HexNAc-Hex-Hex carbohydrate sequence. There was also a fragment ion at m/z 673, which, is caused by double glycosidic cleavage of the 3-linked branch (C₃/Z₂β). This ion thus demonstrated an internal 4-linked GlcNAc substituted with a Fuc at 3-position⁸.

The MS² spectrum of the [M – H⁺]⁻ ion at m/z 1160 at retention time 14.3 min (Fig. 9C) had the same series of C-type fragment ions (C₁, at m/z 487, C₂, at m/z 836, and C₃, at m/z 998), which thus again demonstrated a Hex-(Fuc-)HexNAc-Hex-Hex sequence. The ion at m/z 656 is obtained by a double glycosidic cleavage of the 3-linked branch at C₃ and Z₄α, and demonstrated an internal 3-linked GlcNAc substituted with a Fuc at C-4. Thus, here a blood group B type 1/ALε⁵ heptasaccharide (Galα3(Fucα2)Galβ3(Fucα4)GlcNAcβ3Galβ4Glc) was identified (Fig. 9F).
As above, a blood group A type 1/Le<sup>α</sup> heptasaccharide (GalNAcα3(Fucα2)Galβ3(Fucα4)GlcNAcβ3Galβ4Glc) was identified by MS<sup>2</sup> of the [M − H<sup>+</sup>]<sup>−</sup> ion at m/z 1201 at retention time 14.7 min (Fig. 9D). There was a C-type fragment ion series (C<sub>2</sub> at m/z 528, C<sub>3</sub> at m/z 877, and C<sub>4</sub> at m/z 1039) identifying a HexNAc-(Fuc-)Hex-(Fuc-)HexNAc-Hex-Hex sequence (Fig. 9E), and a C<sub>3</sub>/Z<sub>α</sub> ion at m/z 656, identifying an internal 3-linked GlcNAc substituted with a Fuc at C-4<sup>17</sup> was also obtained. This MS<sup>2</sup> spectrum was very similar to the MS<sup>2</sup> spectrum of reference blood group A type 1/Le<sup>α</sup> heptasaccharide<sup>18</sup>.

Finally, a blood group A type 2/Le<sup>α</sup> heptasaccharide (GalNAcα3(Fucα2)Galβ3(Fucα4)GlcNAcβ3Galβ4Glc) was characterized by MS<sup>2</sup> of the [M − H<sup>+</sup>]<sup>−</sup> ion at m/z 1201 at retention time 20.2 min (Fig. 9E). Again a C-type fragment ion series (C<sub>2</sub> at m/z 528, C<sub>3</sub> at m/z 877, and C<sub>4</sub> at m/z 1039), identifying a HexNAc-(Fuc-)Hex-(Fuc-)HexNAc-Hex-Hex sequence (Fig. 9E), was present, and the C<sub>3</sub>/Z<sub>β</sub> ion at m/z 713 identified an internal 4-linked GlcNAc substituted with a Fuc at 3-position<sup>17</sup>. This MS<sup>2</sup> spectrum and the MS<sup>2</sup> spectrum of reference blood group A type 2/Le<sup>α</sup> heptasaccharide<sup>18</sup> were very similar.

Thus, fraction N-III from GIST II was a complex mixture of blood group A and B heptasaccharides with both type 1 and type 2 core chains, and also Le<sup>α</sup> and Le<sup>β</sup> hexaosylceramides.

**Discussion**

GISTs are the most common primary mesenchymal tumour of the human alimentary tract, counting for less than 1% of all gastrointestinal tumours and about 5% all sarcomas. GISTs originate from the interstitial cells of Cajal in the muscularis propria of the gastrointestinal tract. These cells are specialized smooth muscle cells, which receive inputs from nerve cells within the myenteric and submucosal plexuses, and also communicate electrically with smooth muscle cells in the longitudinal and circular muscle layers<sup>20,21</sup>, and thereby contribute to peristalsis which facilitates propulsion of intestinal contents, and small intestine segmentation which facilitates absorption of nutrients<sup>22</sup>.

The interstitial cells of Cajal and the intestinal circular smooth muscle cells both originate from a common, mesodermally derived mesenchymal pluripotential precursor<sup>22,23</sup>. These mesenchymal progenitors express both the receptor tyrosine kinase c-Kit and smooth muscle myosin heavy chain. Cells that will differentiate into interstitial cells of Cajal maintain the expression of c-Kit, while the cells destined to become smooth muscle cells up-regulate the synthesis of myofilament proteins and down-regulate Kit<sup>24,25</sup>.

It is obvious that the glycosphingolipids of the Cajal cells can not be isolated for structural characterization, and studies of glycosphingolipids of human smooth muscle are rare. However, by binding studies using a battery of monoclonal antibodies, Gillard et al.<sup>26</sup> found that the major non-acid glycosphingolipids of cultured smooth muscle cells, derived from human umbilical cord veins, were lactosylceramide, globotri- and globotetraosylceramide. There were also small amounts of neolactotetraosylceramide, Le<sup>α</sup> pentaosylceramide and globopentaosylceramide/SSEA-3 (Galβ3GalNAcβ3Galβ4(Fucα3)Galβ4Glcβ1Cer). GM3 and Neu5Acα3-GM3 were the major ganglioside, whereas no GD3 ganglioside was detected. Most of the long chain gangliosides had a neolacto core (as e.g. Neu5Acα3β-D-glucopyranosyl-(2→3)-Neu5Acα3β-D-glucopyranosyl-(2→6)-Neu5Acα3β-D-glucopyranosyl-(2→3)-Galβ3GalNAcβ3Galβ4(Fucα3)Galβ4Glcβ1Cer). There was no binding of a monoclonal anti-H type 2 antibody to the smooth muscle cell glycosphingolipids, and binding anti-A or anti-B antibodies was not tested.<sup>26</sup>

In this study, the non-acid and acid glycosphingolipids of three GIST tumours were characterised with the combination of thin-layer chromatography, binding of carbohydrate recognizing ligands and mass spectrometry. The acid fractions of GIST had sulfatide, and GM3 was the major ganglioside. In contrast to the previous study of smooth muscle cell glycosphingolipids, GD3 and the several gangliosides with ganglio core chain (GM1, GD1α, GT1b and GQ1b) were characterized. In the non-acid fractions of the tumours globotetraosylceramide, neolactotetraosylceramide, the x<sub>1</sub> pentaosylceramide, and glycosphingolipids with terminal blood group A, B, H, Le<sup>α</sup>, Le<sup>β</sup> and Le<sup>β</sup> determinants were characterized. The expression of blood group A, B, and H glycosphingolipids was in agreement with the ABO phenotype of the patients, and the relative amounts of the glycosphingolipids with blood group determinants were different in the three tumour samples. Most likely this is a reflection of the blood group determinants expressed by the cells of origin, i.e. the interstitial cells of Cajal.
After the first characterization by binding assays and LC-ESI/MS, the acid glycosphingolipids from GIST I, GIST II, and GIST III provided relevant structures for detailed structural elucidation of GIST glycosphingolipids. Table 3 displays the structures of the acid non-acylated GIST fractions. Overall the glycosphingolipid patterns of the three gastric GISTs had a high similarity with the glycosphingolipids of the human stomach. The non-acid glycosphingolipids of human stomach had a high degree of structural complexity, and the composition of glycosphingolipids differed for individuals of separate blood groups. The major complex glycosphingolipids of blood group O(Rh-)P stomach were neolactotetraosylceramide, the Leα, Leβ, and H type 2 pentaosylceramides, and the Leβ hexaosylceramide. The A(Rh +)P and A(Rh +) x2 stomachs had lactotetraosylceramide, the x1 and the H type 1 pentaosylceramides, neolactohexaosylceramide the Leβ hexaosylceramide and the A type 1/ALAβ heptaosylceramide. The acid human stomach glycosphingolipids characterized were sulfatide and the gangliosides GM3, GD3, GM1, Neu5Acα3-neolactotetraosylceramide, Neu5Acα3-neolactooctaosylceramide, GD1a and GD1b. The major difference observed was the relatively low levels of sulfatide in the GIST tumours compared to the human stomach.

Several gangliosides are overexpressed in cancers, and a substantial number of cancer immunotherapies targeting such gangliosides have been developed. In 1985, a phase I clinical trial with an anti-GD3 antibody demonstrated regression of tumours, activation of T-cells, antibody-dependant-cell-cytotoxicity, and complement dependent cytotoxicity in malignant melanoma patients. More recently an anti-GD2 monoclonal antibody Dinutuximab (Unituxin) has been approved by the Food Drug Administration (FDA) and European Medicines Agency (EMA) for the treatment of high-risk neuroblastomas. Dinutuximab is used in combination antibody Dinutuximab (Unituxin) has been approved by the Food Drug Administration (FDA) and European Medicines Agency (EMA) for the treatment of high-risk neuroblastomas. The non-acid fractions were then acetylated and separated on a second silicic acid column, followed by deacetylation and dialysis. Final purifications are performed by chromatography on DEAE-cellulose and silicic acid columns.

After the first characterization by binding assays and LC-ESI/MS, the acid glycosphingolipids from GIST II were separated on an Iatrobeads column eluted with increasing volumes of methanol in chloroform. The treatment of high-risk neuroblastomas. The non-acid fractions were then acetylated and separated on a second silicic acid column, followed by deacetylation and dialysis. Final purifications are performed by chromatography on DEAE-cellulose and silicic acid columns.

Methods
Glycosphingolipids preparations. The study was conducted according to the tenets of the Declaration of Helsinki, and was approved by the Regional Ethics Committee of Gothenburg (No. 621-18 (decision 2018-09-19)). All patients provided written informed consents before enrolment in the study. Three gastric GIST tumours (denoted GIST I, GIST II and GIST III) were collected at the Sahlgrenska University Hospital. The tumours were kept at −70 °C. The isolation of total acid and total non-acid glycosphingolipids was done by the method described by Karlsson. The tumours were lyophilized, followed by Soxhlet extraction with mixtures of chloroform and methanol (2:1 and 1:9, by volume). The resulting material was pooled and subjected to mild alkaline hydrolysis followed by dialysis. Thereafter non-polar compounds were removed by chromatography on a silicic acid column. Acid and non-acid glycosphingolipids were separated by ion change chromatography on a DEAE-cellulose column. In order to separate the non-acid glycosphingolipids from alkaliphilic phospholipids, the non-acid fractions were then acetylated and separated on a second silicic acid column, followed by deacetylation and dialysis. Final purifications are performed by chromatography on DEAE-cellulose and silicic acid columns.

After the first characterization by binding assays and LC-ESI/MS, the acid glycosphingolipids from GIST II were separated on an Iatrobeads column eluted with increasing volumes of methanol in chloroform. The

Table 3. Glycosphingolipid-derived oligosaccharides from the total non-acid GIST fractions identified by LC-ESI/MS.

This study is the first structural characterization of GIST glycosphingolipids, and demonstrates the presence of glycosphingolipids with blood group ABO and Lewis determinants, along with several complex gangliosides, in these tumors derived from the interstitial cells of Cajal, which are specialized smooth muscle cells. Further studies will be needed to clarify the potential value of these findings for tumour biology, response to therapy and patient survival.
fractions obtained were analyzed by thin-layer chromatography and anisaldehyde/resorcinol detection, and thereafter pooled according to their mobility on thin-layer chromatograms, resulting in five subfractions, which were denoted fractions A-1 to A-5.

The non-acid glycosphingolipids from GIST II were separated on an Iatrobeads column eluted with chloroform:methanol:water (60:35:8, by volume), 29 × 1 ml. The fractions were analysed by thin-layer chromatography, and after pooling according to their mobility on thin-layer chromatograms, three glycosphingolipid-containing fractions were obtained (denoted fractions N-I to N-III).

**Reference glycosphingolipids.** Total acid and non-acid glycosphingolipid fractions were isolated as described\(^\text{14}\). Individual glycosphingolipids were isolated by repeated chromatography on silicic acid columns and by HPLC, and identified by mass spectrometry\(^\text{16,34}\) and \(^1\)H-NMR spectroscopy\(^\text{35}\).
Thin-layer chromatography. Thin-layer chromatography was performed on aluminium- or glass-backed silica gel 60 high-performance thin-layer plates (Merck, Germany). Glycosphingolipid mixtures (40 µg), or pure glycosphingolipids (4 µg), were applied to the plates, and eluted with chloroform/methanol/water 60:35:8 (by volume). Chemical detection was done with anisaldehyde36 or resorcinol37.

Chromatogram binding assays. The carbohydrate binding ligands and dilutions used in the chromatogram binding assays are given in Table 4. Binding of antibodies to glycosphingolipids separated on thin-layer chromatograms was performed as described by Barone et al.40. After elution, the dried thin-layer chromatograms were treated with a mixture of 0.5% polystyrylmethacrylate (w/v) in diethylther/n-hexane (1:5 v/v) for 1 min, and then air-dried. Thereafter followed a 2 h incubation at room temperature with PBS (phosphate-buffered saline, pH 7.3) containing 2% (w/v) bovine serum albumin, 0.1% (w/v) NaN₃ and 0.1% (w/v) Tween 20 (BSA/PBS/TWEEN) to reduce unspecific binding. Then, the chromatograms were incubated for 2 h at room temperature with suspensions of monoclonal antibodies diluted in BSA/PBS/TWEEN. The chromatograms were washed with PBS, and the chromatograms were thereafter incubated for 2 h with 125I-labeled (labeled at room temperature with suspensions of monoclonal antibodies diluted in BSA/PBS/TWEEN) rabbit antimouse antibodies (Pierce/Thermo Scientific) diluted in BSA/PBS/TWEEN. Finally, the chromatograms were washed with PBS, dried and autoradiographed overnight using x-ray films (Carestream; 8,941,114).

Table 4. Carbohydrate binding ligands used in chromatogram binding assays.

| Ligand                  | Clone    | Manufacturer     | Dilution | Isotype |

Endoglycoceraminidase digestion and LC-ESI/MS. The non-acid glycosphingolipids were digested with endoglycoceraminidase and the oligosaccharides thereby obtained were analyzed by LC-ESI/MS as described36,40. Aliquots of the glycosphingolipid fractions were dissolved in methanol:acetonitrile 75:25 (by volume) and separated on a 200 × 0.250 mm column, packed in-house with 5 µm polyclame II particles (YMC Europe GmbH, Dinslaken, Germany). An autosampler, HTC-PAL (CTC Analytics AG, Zwingen, Switzerland) equipped with a chemiluminescent valve (0.25 mm bore) and a 2 µl loop, was used for sample injection. An Agilent 1100 binary pump (Agilent Technologies, Palo Alto, CA) delivered a flow of 250 µl/min, which was split down in an 1/16″ microvolume-T (0.15 mm bore) (Vici AG International, Schenkon, Switzerland) by a stainless steel needle kept at −3.5 kV. Compressed air was used as nebulizer gas. The heated capillary was kept at 207 °C, and the capillary voltage was set to 45 kV. Full scan (m/z 10–1800, two microscans, maximum 100 ms, target value of 30,000) was performed, followed by data-dependent MS² scans (two microscans, maximum 100 ms, target value of 10,000) with normalized collision energy of 35%, isolation window of 2.5 units, activation q = 0.25 and activation time 30 ms). The threshold for MS² was set to 500 counts.

Data acquisition and processing were conducted with Xcalibur software version 2.0.7 (Thermo Scientific, Waltham, MA). Manual assignment of glycosphingolipid sequences was done with the assistance of the Glycoworkbench tool (Version 2.1), and by comparison of retention times and MS² spectra of reference glycosphingolipids.

LC-ESI/MS of native glycosphingolipids. The native glycosphingolipid fractions were analyzed by LC-ESI/MS as described36,40. Aliquots of the glycosphingolipid fractions were dissolved in methanol:acetonitrile 75:25 (by volume) and separated on a 200 × 0.250 mm column, packed in-house with 5 µm polyclame II particles (YMC Europe GmbH, Dinslaken, Germany). An autosampler, HTC-PAL (CTC Analytics AG, Zwingen, Switzerland) equipped with a chemiluminescent valve (0.25 mm bore) and a 2 µl loop, was used for sample injection. An Agilent 1100 binary pump (Agilent Technologies, Palo Alto, CA) delivered a flow of 250 µl/min, which was split down in an 1/16″ microvolume-T (0.15 mm bore) (Vici AG International, Schenkon, Switzerland) by a stainless steel needle kept at −3.5 kV. Compressed air was used as nebulizer gas. The heated capillary was kept at 207 °C, and the capillary voltage was set to 45 kV. Full scan (m/z 10–1800, two microscans, maximum 100 ms, target value of 30,000) was performed, followed by data-dependent MS² scans (two microscans, maximum 100 ms, target value of 10,000) with normalized collision energy of 35%, isolation window of 2.5 units, activation q = 0.25 and activation time 30 ms). The threshold for MS² was set to 500 counts.

Data acquisition and processing were conducted with Xcalibur software version 2.0.7 (Thermo Scientific, Waltham, MA). Manual assignment of glycosphingolipid sequences was done with the assistance of the Glycoworkbench tool (Version 2.1), and by comparison of retention times and MS² spectra of reference glycosphingolipids.

Endoglycoceraminidase digestion and LC-ESI/MS. The non-acid glycosphingolipids were digested with endoglycoceraminidase and the oligosaccharides thereby obtained were analyzed by LC-ESI/MS as described36,40. The glycosphingolipids (50 µg) were reuspended in 100 µl 0.05 M sodium acetate buffer, pH 5.0, containing 120 µg sodium cholate, and sonicated briefly. Thereafter followed a 2 h incubation at room temperature with suspensions of endoglycoceraminidase II from Rhodococcus spp. (Takara Bio Europe S.A., Gennevilliers, France) was added, and the mixture was incubated at 37 °C for 48 h. The reaction was stopped by addition of chloroform/methanol/water to the final proportions 8:4:3 (by volume). Chemical detection was done with anisaldehyde36 or resorcinol37.

Table 4. Carbohydrate binding ligands used in chromatogram binding assays.

| Ligand                  | Clone    | Manufacturer     | Dilution | Isotype |
|-------------------------|----------|------------------|----------|---------|

The oligosaccharides were analyzed in negative ion mode on an LTQ linear quadrupole ion trap mass spectrometer (Thermo Electron, San José, CA). The IonMax standard ESI source on the LTQ mass spectrometer was set to 500 counts. Normalized collision energy was 35%, and an isolation window of 3 u, an activation q = 0.25, an activation time of 30 ms, was used. Selected fractions were also analyzed at m/z 1300–2000. Data acquisition and processing were conducted with version 2.0.7 (Thermo Scientific, Waltham, MA).

Manual assignment of glycan sequences was done on the basis of knowledge of mammalian biosynthetic pathways, with the assistance of the Glycoworkbench tool (Version 2.1), and by comparison of retention times and MS² spectra of oligosaccharides from reference glycosphingolipids15.

Acknowledgements
This study was supported by the Swedish Cancer Foundation (ST; No. 18 0760), Wilhelm & Martina Lundgren Foundation (AT; No. 18 0750), and the Wilhelm & Martina Lundgren Foundation (LA2019-0045). We thank Maria Nilsson, research nurse at Sahlgrenska University Hospital, for help with recruitment of patients. The LM1:1a and LM4:2 antibodies were a kind gift from Dr. M. Blomqvist, Institute of Biomedicine, Department of Clinical Chemistry and Transfusion Medicine, Sahlgrenska Academy at University of Gothenburg, Sweden.

Author contributions
K.S., A.T., O.N. and S.T. conceived and designed the study; L.S., C.J., and T.G. performed experiments and analyzed the data; S.T. wrote the manuscript, which was revised and approved by all authors.

Funding
Open Access funding provided by Gothenburg University Library.

Competing interests
The authors declare no competing interests.
