Abstract

Indeterminate strings are a subclass of non-standard words having non-deterministic nature. In a classic string every position contains exactly one symbol—we say it is a solid symbol—while in an indeterminate string a position may contain a set of symbols (possible at this position); such sets are called non-solid symbols. The most important subclass of indeterminate strings are partial words, where each non-solid symbol is the whole alphabet; in this case non-solid symbols are also called don’t care symbols. We consider the problem of finding a shortest cover of an indeterminate string, i.e., finding a shortest solid string whose occurrences cover the whole indeterminate string. We show that this classical problem becomes NP-complete for indeterminate strings and even for partial words. The proof of this fact is one of the main results of this paper. Our other main results focus on design of algorithms efficient with respect to certain parameters of the input (so called FPT algorithms) for the shortest cover problem. For the indeterminate string covering problem we obtain an $O(nk^2 + 2^k)$-time algorithm, where $k$ is the number of non-solid symbols, while for the partial word covering problem we obtain a running time of $O(nk^2 + 2^\sqrt{k} \log k)$. Additionally, we prove that, unless the Exponential Time Hypothesis is false, no $2^{o(\sqrt{k})} n^{O(1)}$-time solution exists for either problem, which shows that our algorithm for partial words is close to optimal. We also present an algorithm for both problems parameterized both by $k$ and the alphabet size with a simple implementation.

A preliminary version of this article was presented at the 25th International Symposium on Algorithms and Computation (ISAAC 2014), LNCS, vol. 8889, pp. 220–232, Springer (2014) [12].

Keywords: cover of a word, partial word, string with don’t cares, indeterminate string, fixed-parameter tractability

1. Introduction

A classic string is a sequence of symbols from a given alphabet $\Sigma$. In an indeterminate string, some positions may contain, instead of a single symbol from $\Sigma$ (called a solid symbol), a non-empty subset of $\Sigma$. Such a non-solid symbol can mean that the exact symbol at the given position is not known, but is suspected to be one of the specified symbols. The simplest type of indeterminate strings are partial words, in which every non-solid symbol is a don’t care symbol, denoted here $\phi$ (other popular notation is $\ast$), which represents the whole alphabet $\Sigma$.

Motivations for indeterminate strings can be found in computational biology, musicology, and other areas. In computational biology, analogous juxtapositions may count as matches in protein sequences. In fact, the FASTA format\(^1\) representing nucleotide or peptide sequences specifically includes indeterminate letters. In music, single notes may match chords, or notes separated by an octave may match; see [16].

Algorithmic study of indeterminate strings is mainly devoted to pattern matching. The first efficient algorithm was proposed by Fischer and Paterson for strings with don’t care symbols [13]. Faster algorithms for this case were afterwards given in [29, 22, 23, 10, 9]. Pattern matching for general indeterminate strings, known as generalized string matching, was first considered by Abrahamson [1] in the variant that the text is solid. In the most general variant, pattern matching on indeterminate strings probably cannot be solved efficiently in general [19]. There were practical approaches to the problem; see [16, 30] for some recent examples. A survey on partial words, related mostly to their combinatorics, can be found in a book by Blanchet-Sadri [7].

The notion of cover belongs to the area of quasiperiodicity, that is, a generalization of periodicity in which the occurrences of the period may overlap [4]. A cover of a solid string $S$ is a string that covers all positions of $S$ with its occurrences. Covers in solid strings were already extensively studied. A linear-time algorithm finding the shortest cover of a string was given by Apostolico et al. [5] and later on improved into an on-line algorithm by Breslauer [8]. A linear-time algorithm computing all the covers of a string was proposed by Moore and Smyth [28]. Afterwards an on-line algorithm computing all the covers of a string was given by Li and Smyth [26].

Other types of quasiperiodicities are seeds [18, 24] and numerous variants of covers and seeds, including approximate and partial covers and seeds.

Classical periodicities, including periods and the border array, were already extensively studied in the field of indeterminate strings (originating from the papers [15, 17]) and also for partial words (see, e.g., the book of Blanchet-Sadri [7]). Quasiperiodicity is a relaxation of the classical notions of periodicity and, as such, enables one to find approximate repetitive structures. This is important in imprecise data that occurs often in such areas of applications as computational biology and music.

The problem that we consider in this work is as follows (see also Figure 1):

\(^1\)http://en.wikipedia.org/wiki/FASTA_format
COVERING AN INDETERMINATE STRING

Input: an indeterminate string $T$

Output: the length of a shortest solid cover of $T$

We allow the same non-solid symbol to match two different solid symbols for two different occurrences of the same cover. All our algorithms can actually recover an example shortest cover.

![Figure 1: Partial word bb♦♦abb♦♦ba = bb{a,b}{a,b}abb{a,b}{a,b}ba{a,b} with its two shortest covers.](image)

Throughout the paper we use the following notations: $n$ is the length of the given indeterminate string $T$, $k$ is the number of non-solid symbols in $T$, and $\sigma$ is the size of the underlying alphabet $\Sigma$. We assume that $2 \leq \sigma \leq n$ with $\Sigma = \{1, \ldots, \sigma\}$ and that each non-solid symbol in the indeterminate string is represented by a bit vector of size $\sigma$. Thus the size of the input is $O(n + \sigma k)$.

The first attempts to the problem of indeterminate string covering were made in [3, 6, 17]. The common assumption of these papers is that $\sigma = O(1)$. The earliest contribution [17] does not provide a rigorous definition of a cover of an indeterminate string. Using our definition, their algorithm runs in $O(n^2 \log n)$ worst-case time and works only in the case that every border of the text is solid. In [3, 6] a different definition of a cover than ours is used, allowing for the presence of indeterminate symbols in a cover. The contribution [3] considers only so-called conservative indeterminate strings, for which $k = O(1)$, and addresses a problem of checking if its border of a given length $\ell$ is also its cover. They construct an automaton for all solid strings that match the border, being potentially of size $O(\ell \sigma^k)$, and then use it to perform pattern matching on the indeterminate text in time $O(n \ell \sigma^k)$. The algorithm of [6] is very similar; their contribution emphasizes the average time complexity analysis.

Yet another definition of cover of an indeterminate string was recently presented in [2]. They consider a rooted cover to be a prefix of the indeterminate text whose occurrences in the text cover all the positions of the text. Note that a rooted cover does not necessarily need to correspond to any solid cover; e.g., $\varnothing ab$ has a rooted cover of length 1 but no solid cover of length 1. An $O(n^2)$ worst-case time algorithm for computing all rooted covers of the text in the case of $\sigma = O(1)$ is presented in [2].
Our results: We show the following algorithms finding the length of a shortest solid cover of an indeterminate string:

1. an FPT algorithm parameterized by \( k \) and \( \sigma \), with simple implementation and time complexity \( O(nk + \sigma^{|k/2|}k) \);
2. an FPT algorithm parameterized only by \( k \), with time complexity \( O(nk^2 + 2^k k^3) \);
3. for the case of partial words, a faster, \( O(nk^2 + 2^{O(\sqrt{\log k})}) \)-time algorithm.

We also show hardness results, valid already for binary partial words:

1. NP-completeness of the covering problem;
2. that under the Exponential Time Hypothesis, no \( 2^{o(\sqrt{n})} \)-time solution exists for the problem (this also rules out \( 2^{O(\sqrt{n})}n^{O(1)} \)-time algorithms).

The algorithms are presented in Sections 3, 4, and 5, and the hardness results are given in Section 6.

2. Preliminaries

An indeterminate string \( T \) of length \( |T| = n \) over a finite alphabet \( \Sigma \) is a sequence \( T[1] \ldots T[n] \) such that for every index \( i = 1, \ldots, n \), the symbol \( T[i] \) is a non-empty subset of \( \Sigma \). By \( \varepsilon \) we denote the empty indeterminate string. If \( |T[i]| = 1 \), that is, \( T[i] \) represents a single symbol of \( \Sigma \), we say that \( T[i] \) is a solid symbol. For convenience we often write that \( T[i] = c \) instead of \( T[i] = \{c\} \) in this case (\( c \in \Sigma \)). Otherwise, we say that \( T[i] \) is a non-solid symbol. In what follows, by \( k \) we denote the number of non-solid symbols in the considered indeterminate string \( T \) and by \( \sigma \) we denote \( |\Sigma| \). If \( k = 0 \), we call \( T \) a (solid) string.

We say that two indeterminate strings \( U \) and \( V \) match (denoted as \( U \simeq V \)) if \( |U| = |V| \) and for each \( i = 1, \ldots, |U| \) we have \( U[i] \cap V[i] \neq \emptyset \). If \( U \approx V \), we can define an indeterminate string \( U \sqcap V \) with \( (U \sqcap V)[i] = U[i] \cap V[i] \).

**Example 1.** Let

\[
A = a \{b, c, d\}, \quad B = a \{a, b, d\}, \quad C = aa
\]

be indeterminate strings (\( C \) is a solid string). Then:

\[
A \approx B \quad (A \sqcap B = a \{b, d\}) \quad \text{and} \quad B \simeq C \quad (B \sqcap C = aa), \quad \text{but} \quad A \not\approx C.
\]

If all symbols \( T[i] \) are either solid or equal to \( \Sigma \), then \( T \) is called a partial word. In this case, the non-solid “don’t care” symbol is denoted as \( \phi \).

By \( T[i..j] \) we denote a factor \( T[i] \ldots T[j] \) of \( T \). If \( i = 1 \), the factor is called a prefix and if \( j = n \), it is called a suffix of \( T \). We say that an indeterminate pattern \( S \) occurs in an indeterminate text \( T \) at position \( j \) if \( S \approx T[j..j+|S| - 1] \). We define the occurrence set of \( S \) in \( T \), denoted \( \text{Occ}(S, T) \), as the set of all such positions \( j \).

A cover of \( T \) is a solid string \( S \) such that each position \( i \) of \( T \) is covered by an occurrence of \( S \) in \( T \), i.e., \( \text{Occ}(S, T) \cap \{i - |S| + 1, \ldots, i\} \neq \emptyset \) for every \( i = 1, \ldots, n \). If \( S \) is a cover of \( T \), any subset \( C \subseteq \text{Occ}(S, T) \) already satisfying the latter property for all \( i = 1, \ldots, n \) is called a covering set of \( S \); see Fig. 2.
Given an indeterminate string $T$, the length of the longest matching prefix of $T$ can be computed in $O(nk)$ time. For convenience, we also compute the fill-in sequences of $T[1..i] \cap T[i..i + \text{Pref}[i] - 1]$ and store them in a table $\mathcal{F}[1..n]$; see Fig. 3. Values $\text{Pref}[i]$ and $\mathcal{F}[i]$ let us easily characterize all solid prefixes occurring at position $i$:

**Observation 2.** For a solid prefix $S$ of $T$, we have $i \in \text{Occ}(S, T)$ if and only if $\text{Pref}[i] \geq |S|$ and $F_S$ matches a prefix of $\mathcal{F}[i]$. The latter condition can be tested in $O(k)$ time.

In the next lemma we show that the tables $\text{Pref}$ and $\mathcal{F}$ can be computed efficiently. Our algorithm is an adaptation of the kangaroo method [14, 25].

**Lemma 1.** Given an indeterminate string $T$, the prefix table $\text{Pref}$ and the fill-in table $\mathcal{F}$ can be computed in $O(nk + \sigma k^2)$ time.
Proof. For convenience, we assume that the non-solid symbols in $T$ are given as bit vectors (indexed with the alphabet) and the solid symbols have a constant-space representation. This way, $T[i] \cap T[j]$ can be computed in $O(1)$ time if at least one of the symbols is solid; otherwise, such an operation takes $O(\sigma)$ time.

A naive way to determine the value $\text{Pref}[i]$ is to compare $T[j]$ with $T[i+j-1]$ for consecutive indices $j \geq 1$. This approach yields an $O(n^2 + \sigma k^2)$-time algorithm, since each pair of characters is compared at most once. Note that we spend most time matching solid characters. This process can be implemented more efficiently using LCP queries. Let us define a solid string $T_S$ by substituting non-solid symbols in $T$ with distinct characters $1, \ldots, k/\in \Sigma$. Recall that $\text{lcp}_{T_S}(i, j)$ is defined as the longest common prefix of $T_S[i..n]$ and $T_S[j..n]$. Moreover, the string $T_S$ can be preprocessed in $O(n)$ time so that any $\text{lcp}_{T_S}(i, j)$ query can be answered in $O(1)$ time; see [11].

Now, the values $\text{Pref}[i]$ and $\mathcal{F}[i]$ for $i > 1$ can be computed much more efficiently:

| $i$ | $1$ | $2$ | $3$ | $4$ | $5$ | $6$ | $7$ | $8$ | $9$ | $10$ | $11$ | $12$ | $13$ | $14$ | $15$ | $16$ | $17$ | $18$ |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| $T[i]$ | $a$ | $a$ | $b$ | $a$ | $a$ | $b$ | $a$ | $a$ | $a$ | $a$ | $b$ | $a$ | $a$ | $a$ | $a$ | $a$ | $a$ | $b$ |
| $\text{Pref}[i]$ | $18$ | $3$ | $10$ | $1$ | $8$ | $3$ | $1$ | $4$ | $1$ | $4$ | $7$ | $4$ | $5$ | $3$ | $3$ | $1$ | $1$ | $1$ |

Figure 3: The prefix table $\text{Pref}$ and the fill-in table $\mathcal{F}$ for $T = \text{\texttt{aabaabaabaaba}}$. The fill-in sequences $\mathcal{F}[i]$ are shown vertically in the last row.

For each pair of symbols $T[i+j-1], T[j]$ compared in the while-loop, we have $j = 1$, $T[i+j-1] \not\approx T[j]$ (in this case the loop terminates), or at least one of the symbols is non-solid. Hence, there are at most $2k + 1$ iterations for every $i$. No two symbols are compared twice, so the overall running time (across all positions $i$) is $O(nk + \sigma k^2)$. \qed
3. Naive Algorithm Parameterized by $k$ and $\sigma$

We show the tools developed in Section 2 in action in a preliminary algorithm for the shortest cover problem.

Observe that a cover $S$ of $T$ must be a solid prefix of $T$. Hence, its occurrence set $\text{Occ}(S,T)$ is characterized by Observation 2, and thus it can be computed in $O(nk)$ time using the prefix and fill-in tables. The following notion of maxgap is a standard tool allowing for an alternative definition of covers based on the occurrence sets.

For an increasing list of integers $L = [i_1, i_2, i_3, \ldots, i_m]$ of length $m \geq 2$, we define

$$\text{maxgap}(L) = \max\{i_{t+1} - i_t : t = 1, \ldots, m-1\}.$$

Observation 3. A set $\mathcal{P} \subseteq \text{Occ}(S,T)$ is a covering set of a solid string $S$ if and only if $1 \in \mathcal{P}$ and $\text{maxgap}(\mathcal{P} \cup \{n+1\}) \leq |S|$.

To test if $S$ is a cover of $T$, it suffices to use Observation 3 for $\mathcal{P} = \text{Occ}(S,T)$; see Fig. 4. Combined with our initial observation, this yields the following corollary.

Corollary 1. Given an indeterminate string $T$ along with its prefix table $\text{Pref}$ and fill-in table $\mathcal{F}$, one can test in $O(nk)$ time if a given solid string $S$ is a cover of $T$.

The total number of solid prefixes is bounded by $n\sigma k$ (recall that the length and the fill-in sequence represent a solid prefix uniquely).

Note that if a cover $S$ satisfies $|S| \geq \frac{n}{2}$, then $\{1, n - |S| + 1\}$ is already a covering set. Thus, in order to check if $T$ has a cover of length $m \geq \frac{n}{2}$, it suffices to verify if $\text{Pref}[n - m + 1] \geq m$. This lets us focus on covers of length at most $\left\lfloor \frac{n}{2} \right\rfloor$. Moreover, without loss of generality (by possibly reversing the input string $T$) we may assume that $T[1..\left\lfloor \frac{n}{2} \right\rfloor]$ contains at most $\left\lfloor \frac{k}{2} \right\rfloor$ non-solid symbols. This leaves us with $O(n\sigma^{\lfloor k/2 \rfloor})$ solid prefixes to test; see the pseudocode of Prelim-Cover.

**Algorithm Prelim-Cover ($T$)**

**Input:** An indeterminate string $T$ of length $n$ with $k$ non-solid symbols

**Output:** The length of a shortest cover of $T$

if $T[1..\lfloor n/2 \rfloor]$ contains more than $k/2$ non-solid symbols then Reverse $T$;
Compute the tables $\text{Pref}$ and $\mathcal{F}$; \{ $O(nk^2)$ time, Lemma 1 \}
foreach solid prefix $S$ of $T$, $|S| \leq n/2$, in non-decreasing length \{ $O(n\sigma^{\lfloor k/2 \rfloor})$ \} do
Compute $F_S$;
\{ Observation 2, $O(nk)$ time \}
for $i := 1$ to $n$ do
if $\text{Pref}[i] \geq |S|$ and $F_S \approx \mathcal{F}[i][1..|F_S|]$ then insert $(\text{Occ}, i)$;
if $\text{maxgap}(\text{Occ} \cup \{n+1\}) \leq |S|$ then return $|S|$;
for $m := \lfloor n/2 \rfloor + 1$ to $n$ do
if $\text{Pref}[n - m + 1] \geq m$ then return $m$;
Proposition 1. The shortest cover of an indeterminate string of length \( n \) containing \( k \) non-solid symbols can be computed in \( O(n^2k\sigma^{\lfloor k/2 \rfloor}) \) time.

4. Efficient Algorithm Parameterized by \( k \) and \( \sigma \)

We improve upon the result from the previous section in two steps.

4.1. First Improvement

We will show that solid prefixes sharing the same fill-in sequence \( F \) can be tested together in \( O(nk) \) time. We introduce a \texttt{ShortestCover} subroutine which, for a given
Lemma 2. The algorithm ShortestCover(F) correctly computes the shortest cover having the fill-in sequence $F$, if there is any.

Proof. Due to Observation 2, for every string $S$ such that $F_S = F$, we have $\text{Occ}(S,T) = \{ i \in LF : \text{Pref}[i] \geq |S| \}$. Hence, while processing the first pair $(\text{Pref}[i], i) \in DF$ with $\text{Pref}[i] \geq |S|$, we have $M = \text{Occ}(S,T) \cup \{ n+1 \}$.

We check if there is a solid prefix $S$ of $T$ having the fill-in sequence $F$ in the first line of the processing phase (this could not be the case if $T$ is not a partial word and some $F[i]$ does not match the respective non-solid symbol in $T$). If so, then, by Observation 3, $S$ is a cover of $T$ if and only if $\text{maxgap}(M) \leq |S|$.

When processing $(\text{Pref}[i], i) \in DF$ we do not know $|S|$, but we know that it belongs to the interval $[b, \min(p,e)]$. This implies the condition for computing $|S|$ that is used in the pseudocode.

We can also note that the computations in the pseudocode could be ended (with a negative answer) after the first pair $(p, i) \in DF$ with $p \geq e$ has been processed.

Lemma 3. The algorithm ShortestCover(F) works in $O(nk)$ time assuming that the prefix table Pref and the fill-in table $\mathcal{F}$ are available.

Proof. In the preprocessing phase, the (sorted) list $LF$ can be computed in $O(nk)$ time and the set $DF$ can be computed and sorted in $O(n)$ time (e.g., using bucket sort).

In the processing phase, we store an array of pointers mapping each $i \in M$ to the corresponding element of the list $M$. Thanks to it, each $i \in M$ can be removed from $M$ in constant time. Observe that $\text{maxgap}(M)$ may only increase and it can be updated in constant time subject to deletion of elements from $M$. Also note that $n+1$ is never deleted from $M$ and 1 may only be deleted in the last iteration, so $|M| \geq 2$ each time we retrieve $\text{maxgap}(M)$.

The number of potential fill-in sequences of length $\leq \frac{k}{2}$ that we need to test is $\sum_{l=0}^{\lfloor k/2 \rfloor} a^l = O(a^{\lfloor k/2 \rfloor})$, so the overall running time is $O(nk a^{\lfloor k/2 \rfloor})$.

4.2. Second Improvement

The second improvement is based on the fact that the complexity of the function ShortestCover(F) is dominated by preprocessing; the processing phase takes only $O(|LF|)$ time. Let us denote by ShortestCover(F,LF,DF) the sole processing phase of the routine. Observe that having constructed the list $LF$ for a fill-in sequence $F$, we may construct the lists $LF_c$ for all extensions of $F$ by a character $c$; see Fig. 5. This requires a single scan over the list $LF$: we insert each $i \in LF$ to the list $LF_c$ for every $c \in \Sigma$ matching $\mathcal{F}[i]|F|+1]$. The lists $DF_c$ can be constructed in the same way; cf. the pseudocode of the ShortestCoverRec routine.
Algorithm ShortestCoverRec($F, L_F, D_F$)

**Input:** A string $F$ of length $|F| \leq k/2$ together with $L_F$ and $D_F$

**Output:** The length of the shortest cover of $T$ with fill-in sequence of length $\leq k/2$ having a prefix $F$

$m := \text{ShortestCover}(F, L_F, D_F)$;
if $|F| + 1 > k/2$ then return $m$;
foreach $i \in L_F$ do
  foreach $c \in \mathcal{F}[i][|F| + 1]$ do insert($L[c], i$);
  foreach $(p, i) \in D_F$ do
    foreach $c \in \mathcal{F}[i][|F| + 1]$ do insert($D[c], (p, i)$);
  foreach $c \in \Sigma$ do
    if $L[c] \neq \emptyset$ then $m := \min(m, \text{ShortestCoverRec}(Fc, L[c], D[c]))$;
return $m$;

$L_a := 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18$

$L_b := 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 13, 14, 15, 16, 17$

$L_c := 1, 2, 6, 12, 13, 14, 15$

$L_{ab} := 1, 3, 7, 12, 14, 16$

$L_{ba} := 1, 5, 11, 14$

$L_{db} := 1, 3, 5, 7, 9, 14, 16$

$L_{adb} := 1, 7, 12$

$L_{bda} := 1, 3, 12$

$L_{db} := 1, 5, 17$

$L_{db} := 1, 7$

$L_{db} := 1, 3, 5$

Figure 5: Lists $L_F$ for text $T = \text{aababa}bababababa$ and all binary fill-in sequences $F$ of length $\leq 3$. Ambiguous positions (see Section 5) are marked in bold.

The array of pointers used to represent $M$ can be constructed in $O(|L_F|)$ time using $O(n)$ space common to all ShortestCoverRec calls. The overall time complexity of ShortestCoverRec is proportional to the total size of lists $L_F$ across all fill-in sequences $F$ plus $\sigma$ times the total number of recursive calls with $|F| + 1 \leq k/2$. The latter term is $O(\sigma^{[k/2]})$. To bound the former, note that each position $i$ may occur in lists $L_F$ for at most $\sigma_k f$ fill-in sequences $F$ of length $f$, where $k_{i, f}$ is the number of non-solid positions within $\mathcal{F}[i][1..f]$. Moreover, we have $\sum_{i=1}^{n} k_{i, f} \leq k f$, because for any fixed $j$ the symbol $\mathcal{F}[i][j]$ can be non-solid for at most $k$ positions $i$. Since $0 \leq k_{i, f} \leq f$, convexity of the exponential function yields $\sum_{i=1}^{n} \sigma_{i, j} f \leq n - k + k f \sigma f \leq n + k f \sigma f$ (formally, this is due to Karamata’s inequality). Summing up over all lengths $f (0 \leq f \leq [k/2])$, we get a bound of $O(nk + k \sigma^{[k/2]})$ on the overall running time taken by ShortestCoverRec($F$) calls. By Lemma 1, the prefix and fill-in tables can be constructed in $O(nk + \sigma^{k/2})$ time, which is dominated by $O(nk + k \sigma^{k/2})$. Consequently, we arrive at the following result:
Theorem 1. The shortest cover of an indeterminate string with \(k\) non-solid symbols can be computed in \(O(nk + k^{(\lfloor k/2 \rfloor)})\) time.

5. Algorithm Parameterized by \(k\)

Note that in the running time of Theorem 1, the \(O(k^{(\lfloor k/2 \rfloor)})\) term is a contribution of positions \(i\) such that \(F[i]\) contains a non-solid symbol, as each position \(i\) with a solid \(F[i]\) can occur in up to \(|F[i]|\) lists \(L_F\) (cf. Fig. 5). We call the former positions ambiguous, while the latter positions are unambiguous. We shall denote the set of ambiguous positions by \(\mathcal{A}\).

Observation 4. \(|\mathcal{A}| = O(k^2)|\).

We say that a solid prefix \(S\) is a solid-match-prefix of \(T\) if \(F_S\) is equal to a prefix of \(F[i]\) for some position \(i\). The following observation is an important tool in our algorithms.

Observation 5. If a solid prefix \(S\) is not a solid-match-prefix, then \(\text{Occ}(S,T) \subseteq \mathcal{A}\).

Example 3. Consider \(T = ♦♦a♦♦aba♦♦ababaa♦♦a♦♦ab\) (see Fig. 3 and 5); its ambiguous positions are 1, 3, 5, 7, 12, 14, 16. The string aaa is a solid-match-prefix of \(T\), as \(F_{aaa} = aa\) is equal to a prefix of \(F[2]\). On the other hand, aab is a solid prefix of \(T\) but not a solid-match-prefix of \(T\); it occurs at positions \(L_{aab} = 1, 3, 7, 12, 14, 16\), all of which are ambiguous.

We use different tools to find covers of \(T\) which are solid-match-prefixes of \(T\) and those which are not. Dealing with solid-match-prefixes is easier: as there are \(O(nk)\) prefixes \(F\) of fill-in sequences \(F[i]\) across positions \(i\), it is straightforward to devise an \(O(n^2k^2)\)-time algorithm using \(\text{ShortestCover}\) procedure for each \(F\). Below we present an \(O(nk^2)\)-time solution based on techniques developed for Theorem 1.

Theorem 2. The shortest cover among all solid-match-prefixes can be computed in \(O(nk^2)\) time.

Proof. Let \(F\) be the family of fill-in sequences that need to be processed. Formally,

\[
F = \{F[i][1...j] : 0 \leq j \leq |F[i]|, F[i][1...j] \text{ is solid}\}.
\]

Note that \(|F| = O(nk)\) and \(\sum_{F \in F} |F| = O(nk^2)\). For each \(F \in F\) let us denote the set of possible extensions: \(\text{ext}(F) = \{c \in \Sigma : Fc \in F\}\). We say that \(F\) is branching if \(|\text{ext}(F)| \geq 2\) and non-extendible if \(|\text{ext}(F)| = 0\). Note that there are at most \(n\) non-extendible elements in \(F\). Hence, the set \(F\) can be viewed as a compacted TRIE with at most \(n\) leaves (non-extendible strings), at most \(n - 1\) branching nodes (branching strings) and at most \(n\) compacted edges (this is the sum of \(\text{ext}(F)\) over all branching strings \(F\)).
Example 4. For \( T = \varepsilon a a b a b a b a b a a b \) (see Fig. 3), \( \mathbf{F} = \{ \varepsilon, a, b, a a, b a, b b \} \). The branching strings are \( \varepsilon \) and \( b \), and the non-extendible strings are \( a a, b a, \) and \( b b \).

We apply procedure \textit{ShortestCover} for each \( F \in \mathbf{F} \). We follow the lines of \textit{ShortestCoverRec} to construct the lists \( L_F \) (and \( D_F \)) for \( F \in \mathbf{F} \). The only difference in the implementation is that, when checking if a given element \( i \in L_F \) should be inserted into \( L_{Fc} \), we only consider \( c \in \text{ext}(F) \). Our goal now is to bound the total size of \( L_F \) across \( F \in \mathbf{F} \).

If \( \mathcal{F}[i][|F|+1] \) is non-solid and \( F \) is branching, we process such \( i \in L_F \) in time \( O(|\text{ext}(F)|) \), iterating over all characters \( c \in \text{ext}(F) \). As we already noticed, the sum of \( |\text{ext}(F)| \) across all branching fill-in sequences \( F \) is at most \( n \), and, for a given \( F \), \( \mathcal{F}[i][|F|+1] \) can be non-solid for at most \( k \) positions \( i \). Consequently, this case contributes \( O(nk) \) to the total running time. In particular, the total number of elements inserted this way to the lists \( L_F \) is also \( O(nk) \).

Otherwise, we have just one character \( c \) to consider and we process such \( i \in L_F \) in \( O(1) \) time, possibly inserting a copy of \( i \) to \( L_{Fc} \). This way, for each of the \( n \) elements originally introduced in \( L_e \) and for each of \( O(nk) \) elements introduced using the previous case we create a chain of up to \( k \) such copies. Hence, the total size of the lists \( L_F \) is \( O(nk^2) \) and so is the total running time of the \textit{ShortestCover} instances. Apart from that, we only use Lemma 1, whose running time \( O(nk + \sigma k^2) \) is dominated by \( O(nk^2) \).

The key property of solid-match-prefixes \( S \) was that \( S \) could be determined by \( |S| \) and the fill-in sequence \( \mathcal{F}[i] \) at a single position \( i \). In general, in case of a partial word it suffices to use up to \( 2\sqrt{k} \) positions to retrieve all solid characters of the cover. This fact can be stated generally for any indeterminate string as follows.

**Lemma 4.** Let \( S \) be a cover of an indeterminate string \( T \) and let \( C \) be its minimal covering set. There exists a subset \( \mathcal{R} \) of \( \mathcal{C} \) of size at most \( 2\sqrt{k} \) such that, for every position \( j \) of the fill-in sequence \( F_S \), if \( F_S[j] = \mathcal{F}[i][j] \) for some \( i \in \mathcal{C} \), then \( F_S[j] = \mathcal{F}[i][j] \) for some \( i \in \mathcal{R} \).

**Proof.** We shall prove that any minimal subset \( \mathcal{R} \) satisfying the desired property is of size at most \( 2\sqrt{k} \). Since \( \mathcal{R} \) is minimal, for every \( i \in \mathcal{R} \) there must be a position \( j \) which prevents the removal of \( i \) from \( \mathcal{R} \), i.e., such that \( \mathcal{F}[i'][j] \) is non-solid for every \( i' \in \mathcal{R}, i' \neq i \). This means that each \( i \in \mathcal{R} \) implies \( r - 1 \) non-solid positions in \( T \) that correspond to \( \mathcal{F}[i'][j] \) for \( i' \in \mathcal{R} \) and some \( 1 \leq j \leq |F_S| \). This is at least \( r \cdot (r - 1) \) non-solid positions in total, where \( r = |\mathcal{R}| \).

Some of these \( r \cdot (r - 1) \) non-solid positions may be the same in \( T \). However, by Observation 1, any non-solid position is covered by at most two occurrences of \( S \) in \( \mathcal{C} \). Therefore, \( r \cdot (r - 1) \leq 2k \) and, consequently, \( r \leq 2\sqrt{k} \).

For a set of positions \( \mathcal{P} \), we introduce an auxiliary operation \textit{TestCover} \((\mathcal{P})\) which checks if there is a cover of \( T \) for which \( \mathcal{P} \) is a covering set and, if so, retrieves such a
Lemma 5. After $O((n + 2k)k^2)$-time preprocessing, TestCover ($\mathcal{P}$) can be implemented in $O(|\mathcal{P}|k)$ time.

Proof. Let $m = n + 1 - \max \mathcal{P}$. By Observation 3, $\mathcal{P}$ can be a covering set for a cover of length $m$ only if $1 \in \mathcal{P}$ and $\maxgap(\mathcal{P} \cup \{n + 1\}) \leq m$. These conditions can be easily checked in $O(|\mathcal{P}|)$ time without any preprocessing.

Now, it suffices to check if there is a solid string $S$ of length $m$ such that $T[i..i + m - 1] \approx S$ for all $i \in \mathcal{P}$. Such a string certainly does not exist if $\text{Pref}[i] < m$ for some $i \in \mathcal{P}$. Otherwise, let the set $Y$ contain positions of all don’t care symbols in $T[1..m]$. We need to check, for each $j \in Y$, how many solid symbols does the set

$$X_j = \{T[i - 1 + j] : i \in \mathcal{P}\}$$

contain. If there are two different solid symbols in this set, then there is no such cover. If there is exactly one symbol, then it suffices to check in $O(|\mathcal{P}|)$ time if this symbol matches all the non-solid symbols in this set. Otherwise, if there are no such solid symbols, we will retrieve the result for such $X_j$ from the results of preprocessing. The processing phase takes $O(|\mathcal{P}|k)$ time, as there are $|Y| \leq k$ positions $j$ to test.

The preprocessing phase starts with computing $\text{Pref}$ table using Lemma 1 in $O(nk^2)$ time. Let $Z$ be the set of all non-solid positions in $T$. We wish to compute, for each subset $X \subseteq Z$, a Boolean value stating if there is a single solid symbol matching all the positions in $X$. First, for every character $c \in \Sigma$, we compute a subset $Z_c \subseteq Z$ of non-solid positions containing $c$. This takes $O(\sigma k)$ time. Initially, we set the Boolean values of the sets $Z_c$ to ‘true’ and the remaining values to ‘false’. Finally, we scan all subsets of $Z$ in a non-increasing order of sizes to compute the final answer, that is, whether $X \subseteq Z_c$ for some $c \in \Sigma$. To process $X$, it suffices to ‘or’ the value at $X$ with each of the values at $X \setminus \{x\}$ for each $x \in X$. Altogether, this preprocessing takes $O(2^k \cdot k^2)$ time.

We apply the TestCover routine to obtain an efficient solution for covering an indeterminate string with non-solid-match prefixes, hence, for the main problem. The algorithm of Theorem 3 is summarized in the pseudocode of the FastCover algorithm.

Theorem 3. The shortest cover of an indeterminate string $T$ of length $n$ with $k$ non-solid symbols can be computed in $O(nk^2 + 2k^3)$ time.

Proof. Let $S$ be a shortest cover of the given indeterminate string $T$, let $m$ be its length, and let $\mathcal{C}$ be its minimal covering set.

By Theorem 2, if $S$ is a solid-match-prefix, then it can be computed in $O(nk^2)$ time. Hence, we may assume that $S$ is not a solid-match-prefix. By Observation 5 this means that $\mathcal{C} \subseteq \mathcal{A}$. A straightforward approach, leading to an $O((n + 2k^2)k^2)$-time algorithm, would be to apply the TestCover procedure for all subsets of $\mathcal{A}$. Below, we develop a much more efficient solution, which is based on a distinction into two cases:

Case 1: There exists an index $j \in \{1, \ldots, |F_3|\}$ such that $\mathcal{F}[i][j]$ is non-solid for every $i \in \mathcal{C}$. We have $O(k \cdot 2^k)$ possible covering sets $\mathcal{C}$: there are $k$ possibilities for $j$, and at most $2^k$ possible subsets of $\{i' : T[i'][j] \text{ is non-solid}\}$. Each such set $\mathcal{C}$ has size at most $k$. Using the TestCover routine, we process these sets in $O(k^3 \cdot 2^k)$ total time.
Algorithm \textit{FastCover}(T)

\textbf{Input:} An indeterminate string \( T \) of length \( n \) with \( k \) non-solid symbols

\textbf{Output:} The length of the shortest cover of \( T \)

\( \text{result} := \) the length of the shortest solid-match-prefix cover of \( T \); \( \{ O(nk^2) \text{ time} \} \)

\{ Implementation of Case 1 \}

for \( j := 1 \) to \( k \) do
   foreach \( C \subseteq \{ i' : T[i'][j] \text{ is non-solid} \} \) do
      if \text{TestCover}(C) then
         \( \text{result} := \min(\text{result}, n + 1 - \max C) \);

\{ Implementation of Case 2 \}

foreach \( m \in \{ n + 1 - a : a \in \Sigma \} \) do
   \( f := \) the number of non-solid symbols in \( T[1..m] \);
   foreach \( R \subseteq \Sigma, |R| \leq 2\sqrt{k} \) do
      if there exists \( i \in R \) such that \( \text{Pref}[i] < m \) then continue;
      for \( j := 1 \) to \( f \) do
         \[ X := \{ \mathcal{F}[i][j] : i \in R \} \cap \Sigma; \]
         \[ F[j] := \text{any element of } X \text{ or any element of } \Sigma, \text{ if } X = \emptyset; \]
         \( \mathcal{P} := \emptyset; \)
         foreach \( i \in R \) do
            if \( \text{Pref}[i] \geq m \) and \( F \approx \mathcal{F}[i][1..f] \) then insert(\( \mathcal{P}, i \));
            if \text{TestCover}(\( \mathcal{P} \)) then
               \( \text{result} := \min(\text{result}, m) \);
   return \( \text{result} \);
Case 2: For every \( j \in \{1, \ldots, |F_S|\} \) there exists an index \( i \in \mathcal{C} \) such that \( \mathcal{F}[i][j] \) is solid. By Lemma 4 there is a subset \( \mathcal{R} \subseteq \mathcal{C} \) of size at most \( 2\sqrt{k} \) such that for every \( j \in \{1, \ldots, |F_S|\} \) there exists an index \( i \in \mathcal{R} \) such that \( \mathcal{F}[i][j] \) is solid. Note that, for a fixed length \( m \), given such a subset \( \mathcal{R} \) we can uniquely retrieve \( F_S \) (and \( S \)). Moreover, \( \text{Occ}(S, T) \cap \mathcal{A} \) must be a covering set of \( S \) (we do not require to compute \( \mathcal{C} \)).

This leads to the following algorithm resulting in \( k^2 \cdot 2^{O(\sqrt{k} \log k)} \) sets to test. First, we have \( |\mathcal{A}| \leq k^2 \) possibilities for the length of the cover \( m \) (since \( n - m + 1 \in C \subseteq \mathcal{A} \)). Next, we generate all subsets of \( \mathcal{A} \) of size at most \( 2\sqrt{k} \). The number of such sets is:

\[
\sum_{p=1}^{\lfloor 2\sqrt{k} \rfloor} \binom{|\mathcal{A}|}{p} \leq \sum_{p=1}^{\lfloor 2\sqrt{k} \rfloor} (k^2)^p \leq \sum_{p=1}^{\lfloor 2\sqrt{k} \rfloor} 2^{k^2 p} \leq 2^{k^2 \cdot 2\sqrt{k} \cdot \sqrt{k}} = 2^{O(\sqrt{k} \log k)}.
\]

For every generated set \( \mathcal{R} \) we check if \( \text{Pref}[i] \geq m \) for each \( i \in \mathcal{R} \) and, for every \( j \in \{1, \ldots, |F_S|\} \), we verify whether \( \{ \mathcal{F}[i][j] : i \in \mathcal{R} \} \) contains exactly one solid symbol. If so, we construct the fill-in sequence \( F_S \) by taking the unique symbol as \( F_S[j] \). Otherwise, we may reject \( \mathcal{R} \). (In the pseudocode, for simplicity, we select an arbitrary letter of \( \Sigma \) in this case.)

Finally, we use Observation 2 to check if \( \text{Occ}(S, T) \cap \mathcal{A} \) is a covering set of \( S \). Note that we may assume \( \text{Occ}(S, T) \subseteq \mathcal{A} \), so this takes \( O(k^3) \) time. The total running time in this case is \( O(k^4 \cdot 2^{O(\sqrt{k} \log k)}) = 2^{O(\sqrt{k} \log k)} \).

We conclude with an algorithm for partial words which is faster than the generic solution for indeterminate strings.

**Theorem 4.** The shortest cover of a partial word of length \( n \) with \( k \) don’t care symbols can be computed in \( 2^{O(\sqrt{k} \log k)} + O(nk^2) \) time.

**Proof.** Let \( S \) be a shortest cover of a given partial word \( T \), let \( m \) be its length, and let \( \mathcal{C} \) be its minimal covering set. As in the proof of Theorem 3, application of Theorem 2 lets us assume that \( \mathcal{C} \subseteq \mathcal{A} \).

By Lemma 4 there is a set \( \mathcal{R} \subseteq \mathcal{C} \) of size at most \( 2\sqrt{k} \) such that for every position \( j \) in \( F_S \) we either have \( \mathcal{F}[i][j] = \phi \) for each \( i \in \mathcal{C} \) or \( F_S[j] = \mathcal{F}[i][j] \) for some \( i \in \mathcal{R} \). Given the length \( m \) and the set \( \mathcal{R} \), we may retrieve \( F_S[j] \) for the latter positions, while for the former ones substituting \( F_S[j] \) with an arbitrary character yields a solid prefix \( S' \) which is still a cover with covering set \( \mathcal{C} \). Moreover, \( \mathcal{C} \subseteq \text{Occ}(S', T) \cap \mathcal{A} \) and the latter is also a covering set of \( S' \).

Consequently, we obtain an algorithm very similar to that used in Case 2 in the proof of Theorem 3: we have \( O(k^3) \) possibilities for \( m \), \( 2^{O(\sqrt{k} \log k)} \) possibilities for \( \mathcal{R} \), and we verify each in \( O(k^3) \) time. The overall running time is \( 2^{O(\sqrt{k} \log k)} + O(nk^2) \). \( \square \)

6. Hardness Results

Hardness results obtained for partial words remain valid in the more general setting of the indeterminate strings, so in this section we restrict our considerations to partial words. We consider the following decision problem.
Problem 1 (Shortest Cover in Partial Words). Given a partial word $T$ of length $n$ over an alphabet $\Sigma$ and an integer $d$, decide whether $T$ has a solid cover of length at most $d$.

We devise a reduction from the CNF-SAT Problem. Recall that in this problem we are given a Boolean formula with $p$ variables which is a conjunction of $m$ clauses $C_1 \land C_2 \land \ldots \land C_m$, where each clause $C_i$ is a disjunction of (positive or negative) literals, and our goal is to check if there exists an interpretation that satisfies the formula. Below we present a reformulation of the CNF-SAT Problem which is more suitable for our proof.

Problem 2 (Universal Mismatch). Given a collection of $m$ binary partial words $W_1, \ldots, W_m$ each of length $p$, check if there exists a binary partial word $V$ of length $p$ such that $V \not\approx W_i$ for any $i$.

Observation 6. Given an instance of the CNF-SAT Problem with $p$ variables and $m$ clauses, in linear time one can construct an equivalent instance of the Universal Mismatch Problem with $m$ partial words each of length $p$. The resulting mapping of instances is bijective and its inverse can also be computed in linear time.

Example 5. Consider a formula
\[
\phi = (x_1 \lor x_2 \lor \neg x_3 \lor x_5) \land (\neg x_1 \lor x_4) \land (\neg x_2 \lor x_3 \lor \neg x_5)
\]
with three clauses and five variables. In the corresponding instance of the Universal Mismatch Problem, for each clause $C_i$ we construct a partial word $W_i$ such that $W_i[j] = 0$ if $x_j \in C_i$, $W_i[j] = 1$ if $\neg x_j \in C_i$, and $W_i[j] = \diamond$ otherwise:

$W_1 = 001\diamond0$, $W_2 = 1\diamond0\diamond$, $W_3 = \diamond1011$.

The interpretations $(1,0,1,1,0), (1,1,1,1,0)$ satisfy $\phi$. They correspond to partial words $10110, 11110$ and $1\diamond110$, none of which matches any of the partial words $W_1, W_2, W_3$.

Consider an instance $W = (W_1, \ldots, W_m), |W_j| = p$, of the Universal Mismatch Problem. We construct a binary partial word $T$ of length $O(p(p+m))$ which is equivalent to $W$ as an instance of the Shortest Cover in Partial Words Problem with $d = 4p+3$.

We define a morphism
\[ h: 0 \to 0100, 1 \to 0001, \diamond \to 0000. \]

Structure of the NP-hardness proof. We construct $T$ so that a partial word $V$ of length $p$ is a solution to $W$ if and only if $S = 11h(V)0$ covers $T$. The word $T$ is of the form $11\pi0\beta_1 \ldots \beta_p \gamma_{W_1} \ldots \gamma_{W_m}$, where $\pi = 001000$ and $\beta_j, \gamma_W$ are gadgets to be specified later. These gadgets are chosen so that every cover of $T$ has length at least $d$ and every $d$-cover of $T$ (i.e., every cover of $T$ of length exactly $d$) is a $d$-cover of each gadget string $\beta_j$ and $\gamma_W$. Here, the prefix $11\pi00$ and all $\beta_j$ are consistency gadgets which guarantee that any $d$-cover is of the form $11h(V)0$ for some partial word $V$ of length $p$. On the other hand, $\gamma_W$ are constraint gadgets which do not allow $V$ to match $W$. 

16
6.1. Consistency Gadgets

The prefix $11\pi^p0$ of $T$ enforces that any $d$-cover $S$ of $T$ is of the form $S = 11s_1\ldots s_p0$ where $s_j = \pi$ for each $j$. Thus, in order to make sure that $S$ is of the form $11h(V)0$ for some partial word $V$, it suffices to rule out the possibility that $s_j = 0101$ for some $j$. To this end, we define

$$\beta_j = 11\pi^{p-1}0\circ^{j+1}000\circ^d.$$ 

![Sample gadget $\beta_j$ for $j = 2$ and $p = 3$ with occurrences of a pattern $11h(101)0$. Positions $d - 2$ and $d$ are marked in grey.](image)

Observation 7. Suppose $S$ is a solid string such that $S \approx 11\pi^p0$. Then $S$ occurs as a prefix and as a suffix of $\beta_j$.

Lemma 6. Let $S = 11s_1\ldots s_p0$ be a solid string with $s_i = \pi$ for each $i$. Then $S$ covers $\beta_j$ if and only if $s_j \neq 0101$.

Proof. ($\Leftarrow$) By Observation 7, $S$ occurs in $\beta_j$ at positions 1 and $|\beta_j| - |S| + 1 = d + 4j + 1$. If $s_j \neq 0101$, then $s_j = 0100$ and $S$ also occurs at position $d - 2$, or $s_j = 0001$ and $S$ occurs at position $d$, or $s_j = 0000$ and $S$ occurs at both positions $d - 2$ and $d$; see Figure 6. Consequently, $S$ covers $\beta_j$ since

$$\maxgap(1, d - 2, d + 4j + 1) \leq d \quad \text{and} \quad \maxgap(1, d, d + 4j + 1) \leq d.$$ 

($\Rightarrow$) If $S$ covers $\beta_j$, it must have an occurrence at some position $q$ with $2 \leq q \leq d + 1$. In particular, $11$ must occur at position $q$, which further restricts $q \in \{d - 3, d - 2, d - 1, d, d + 1\}$. If $s_j = 0101$, then we would need to have $\beta_j[q + 4j - 1] = 1$ and $\beta_j[q + 4j + 1] = 1$; see Figure 6. However, $\beta_j[d + 4j - 2] = \beta_j[d + 4j - 1] = \beta_j[d + 4j] = 0$. We get a contradiction for each of the five possible values of $q$. Consequently, $S$ cannot have $s_j = 0101$.

Corollary 2. A solid string $S \approx 11\pi^p0$ is a cover of each partial word $\beta_j$ for $j = 1, \ldots, p$ if and only if $S = 11h(V)0$ for a binary partial word $V$ of length $p$.

6.2. Constraint Gadgets

We encode a constraint $V \neq W$ using a gadget

$$\gamma_W = 11\mu(W^R)0100^d$$

where $W^R$ denotes the reverse of $W$ and $\mu$ is the following morphism:

$$\mu : \quad 0 \rightarrow \circ \circ \circ \circ, \quad 1 \rightarrow 0 \circ \circ \circ, \quad \circ \rightarrow 0 \circ \circ \circ.$$
Observation 8. Suppose $S$ is a solid string such that $S \approx 11\pi^p0$ and $W$ is a partial word of length $p$. Then $S$ occurs as a prefix and as a suffix of $\gamma_W$.

Before we proceed with a proof that $\gamma_W$ indeed encodes the constraint, let us characterize the relation between morphisms $\mu$ and $h$.

Lemma 7. Let $c, c' \in \{0,1,\phi\}$, and let $X, Y$ be partial words of the same length. Then $11h(0)c0$ occurs in $\mu(c'Y)010\phi\phi$ if and only if $c \neq c'$.

![Figure 7: Illustration of Lemma 7: an occurrence of $11h(0)c0$ in $\mu(c'Y)010\phi\phi$ for (a) $Xc = 0101, c'Y = 01\phi0$; (b) $Xc = 000, c'Y = 100$. In general, $11h(0)c0$ is a prefix of $\mu(c'Y)010\phi\phi$ if $c = 1$ and $c' = 0$, and a suffix — if $c = 0$ and $c' = 1$.]

Proof. Let $P = 11h(0)c0, Q = \mu(c'Y)010\phi\phi$ and $\ell = |P|$.

($\Rightarrow$) Note that $|Q| = \ell + 2$, so $P$ can occur in $Q$ only at positions $p \in \{2,3\}$. Moreover, $p = 2$ is impossible because $Q[\ell - 1] = 1$ and $P[\ell - 2] = 0$ (since $h(c') \approx \pi = 0\phi\phi$); see Figure 7. Thus, $P$ can occur in $Q$ only as a prefix or as suffix.

Suppose $P$ occurs as a suffix of $Q$. Note that $P$ begins with 11, so $\mu(c') \approx 11\phi\phi$ and thus $c' = 0$. Moreover, $Q$ ends with $010\phi\phi$, so $h(c) \approx \phi\phi01$ and $c = 1$. Similarly, if $P$ occurs as a suffix of $Q$, then $\mu(c'Y) \approx \phi\phi11$, so $c' = 1$, and $h(c) \approx 010\phi\phi$, so $c = 0$. Consequently, $c \neq c'$ in either case.

($\Leftarrow$) Observe that $\mu(c'Y)$ has $\phi$’s at all even positions, and $\phi$’s or zeroes at all odd positions, while, $h(0)c0$ has zeroes at all odd positions. Thus, any mismatch preventing an occurrence of $P$ as a prefix or as a suffix of $Q$ must be due to the initial 11 in $P$ or the terminal $010\phi\phi$ in $Q$. The corresponding positions in $Q$ and $P$ depend only on $c'$ and $c$, respectively. As $c \neq c'$, we have $c = 1$ and $c' = 0$ or $c = 0$ and $c' = 1$. In the former case $P$ occurs in $Q$ as a prefix, and in the latter it occurs as a suffix; see Figure 7.

Lemma 8. Let $V$ and $W$ be binary partial words of length $p$. Then $S = 11h(0)c0$ covers $\gamma_W$ if and only if $V \neq W$.

Proof. ($\Leftarrow$) Note that, by Observation 8, $S$ always matches both a prefix and a suffix of $\gamma_W$. The only positions which are not covered by these two occurrences of $S$ form the middle 10 factor $\gamma_W[d + \ldots d + 2]$; see Figure 8. If $V \neq W$, there exists a position $i \in \{1,\ldots,p\}$ such that $V[i] \neq W[i]$. By Lemma 7, $11h(0)c0$ occurs in $\mu((W[1..i])^R)010\phi\phi$. This occurrence extends to an occurrence of $11h(0)c0$ in
\[ \mu((W[1..i])^{k})^{0}10_{i}^{d-4} \\], and consequently an occurrence of 11h(V)0 in \( \gamma_{W} \) covering the middle 10 factor \( \gamma_{W}[d+1..d+2] \). Thus, \( S = 11h(V)0 \) is a cover of \( \gamma_{W} \).

\((\Rightarrow)\) Let \( r \) be the position in \( \gamma_{W} \) corresponding to an occurrence of 11h(V)0 that covers \( \gamma_{W}[d+2] \). Note that \( S \) begins with 11, so \( r < d-1 \). Let \( i = \lceil \frac{d-r}{2} \rceil \), i.e., \( i \) is the smallest value such that the occurrence of 11h(V[1..i])0 at position \( r \) covers the middle 10 factor \( \gamma_{W}[d+1..d+2] \). Now, observe that 11h(V[1..i])0 occurs in \( \mu((W[1..i])^{k})^{0}10_{i}^{d-4} \), so Lemma 7 implies that \( V[i] \neq W[i] \), and thus \( V \neq W \). \hfill \Box

6.3. Main Hardness Results

\textbf{Lemma 9.} Given an instance \( W \) of the Universal Mismatch Problem with \( m \) partial words of length \( p \), one compute in \( O(|T|) \) time a binary partial word \( T \) of length \( \Theta((p+m)^{2}) \) for which the Shortest Cover in Partial Words Problem with \( d = 4p+3 \) is equivalent to \( W \).

\textbf{Proof.} Let

\[ T = 11h^{0}0_{1} \ldots 0_{p} \gamma_{W_{1}} \ldots \gamma_{W_{m}}. \]

Each gadget \( \beta_{j}, \gamma_{W} \) is of length \( \Theta(p) \), so \( |T| = \Theta((p+m)^{2}) \). Moreover, \( T \) can clearly be constructed in \( \Theta((p+m)^{2}) \) time. It suffices to prove that \( W \) is a YES-instance of the Universal Mismatch Problem if and only if \( T, 4p+3 \) is a YES-instance of the Shortest Cover in Partial Words Problem.

\((\Rightarrow)\) Suppose \( W \) is a YES-instance with a solution \( V \). We shall prove that a solid string \( S = 11h(V)0 \) of length \( d \) is a cover of \( T \). We have \( S \approx 111^{0}0^{0} \) by definition of \( h \) and \( \pi \); in particular \( S \) covers \( 111^{0}0^{0} \). Moreover, \( S \) covers each \( \beta_{j} \) by Corollary 2, and for each \( i \) it covers \( \gamma_{W_{i}} \) by Lemma 8 and due to the fact that \( V \neq W_{i} \). Thus, \( T \) is a concatenation of partial words covered by \( S \), and thus \( T \) itself is also covered by \( S \).

\((\Leftarrow)\) Suppose that \( T \) has a solid cover \( S \) with \( |S| \leq d \). Clearly, \( |S| > 1 \) since both 0 and 1 occur as solid symbols in \( T \). Thus, \( S \) begins with 11. Note that 11 does not occur in \( T \) at any position \( p \) with \( 1 < p \leq d \). Consequently, \( S \) cannot be shorter than \( d \), i.e., \( S \approx 111^{0}0^{0} \).

By Observations 7 and 8, \( S \) occurs both as a prefix and as a suffix of each gadget words \( \beta_{j} \) and \( \gamma_{W} \). It also covers their superstring \( T \), so \( S \) covers each of the gadget
Theorem 5. The shortest cover in partial words problem is NP-complete even for the binary alphabet.

Proof. Equivalence between the CNF-SAT problem and universal mismatch problem (Observation 6) and the reduction above imply that the shortest cover in partial words problem is NP-hard. It belongs to NP, since checking whether a given solid string is a cover can be implemented in polynomial time.

The exponential time hypothesis (ETH) [20, 27] asserts that for some \( \varepsilon > 0 \) the 3-CNF-SAT problem cannot be solved in \( O(2^{\varepsilon p}) \) time, where \( p \) is the number of variables. By the Sparsification Lemma [21, 27], ETH implies that for some \( \varepsilon > 0 \) the 3-CNF-SAT problem cannot be solved in \( O(2^{\varepsilon (p+m)}) \) time, and consequently in \( 2^{o(p+m)} \) time, where \( m \) is the number of clauses. Thus, Observation 6 and Lemma 9 also imply the following result.

Theorem 6. Unless the exponential time hypothesis is false, there is no \( 2^{o(\sqrt{n})} \)-time algorithm for the shortest cover in partial words problem. In particular, there is no \( 2^{o(\sqrt{k})} n^{O(1)} \)-time algorithm for this problem.

7. Conclusions

We considered the problems of finding the shortest solid cover of an indeterminate string and of a partial word. The main results of the paper are fixed-parameter tractable algorithms for these problems parameterized by \( k \), that is, the number of non-solid symbols in the input. For the partial word covering problem we obtain an \( O(nk^2 + 2^{O(\sqrt{k}\log k)}) \)-time algorithm whereas for covering a general indeterminate string we obtain an \( O(nk^2 + 2^{O(k)}) \)-time algorithm.

One open problem is whether the shortest cover of a general indeterminate string can be found as fast as the shortest cover of a partial word. Another question is to close the complexity gap for the latter problem, considering the lower bound resulting from the exponential time hypothesis, which yields that no \( 2^{o(\sqrt{k})} n^{O(1)} \)-time solution exists for this problem.
