In this paper, we investigate the generalised monogamy inequalities of convex-roof extended negativity (CREN) in multi-level systems. The generalised monogamy inequalities provide the upper and lower bounds of bipartite entanglement, which are obtained by using CREN and the CREN of assistance (CRENOA). Furthermore, we show that the CREN of multi-qubit pure states satisfies some monogamy relations. Additionally, we test the generalised monogamy inequalities for qudits by considering the partially coherent superposition of a generalised W-class state in a vacuum and show that the generalised monogamy inequalities are satisfied in this case as well.

Quantum entanglement is one of the most important physical resources in quantum information processing. As distinguished from classical correlations, quantum entanglement cannot be freely shared among many objects. We call this important phenomenon of quantum entanglement monogamy. The property of monogamy may be as fundamental as the no-cloning theorem, which gives rise to structures of entanglement in multipartite settings. Some monogamy inequalities have been studied to apply entanglement to more useful quantum information processing. The property of monogamy property has been considered in many areas of physics: it can be used to extract an estimate of the quantity of information about a secret key captured by an eavesdropper in quantum cryptography, as well as the frustration effects observed in condensed matter physics and even black-hole physics.

The monogamy relation of entanglement is a way to characterise different types of entanglement distribution. The first monogamy relation was named the Coffman-Kundu-Wootters (CKW) inequality. The monogamy property can be interpreted as the following statement: the amount of entanglement between A and B plus the amount of entanglement between A and C cannot be greater than the amount of entanglement between A and the BC pair. Osborne and Verstraete later proved that the CKW inequality also holds in an n-qubit system.

Other types of monogamy relations for entanglement were also proposed. Studies have found that the monogamy inequality holds in terms of some entanglement measures, negativity, squared CREN, entanglement of formation, Rényi entropy and Tsallis entropy. The monogamy property of other physical resources, such as discord and steering, has also been discussed. There can be several inequivalent types of entanglement among the subsystems in multipartite quantum systems, and the amount of different types of entanglement might not be directly comparable to one another. Regula et al. studied multi-party quantum entanglement and found that there was strong monogamy. Additionally, generalised monogamy relations of concurrence for N-qubit systems were also proposed by Zhu et al.

In this paper, we study the generalised monogamy inequalities of CREN in multi-qubit systems. We first recall some basic concepts of entanglement measures. Then, monogamy inequalities are given by the concurrence and negativity of the n-qubit entanglement. Furthermore, we consider some states in a higher-dimensional quantum system and find that the generalised monogamy inequalities also hold for these states. We specifically test the generalised monogamy inequalities for qudits by considering the partially coherent superposition of a generalised W-class state in a vacuum, and we show that the generalised monogamy inequalities are satisfied in this case as well. These relations also give rise to a type of trade-off in inequalities that is related to the upper and lower bounds of CREN. It shows the bipartite entanglement between AB and the other qubits: especially under partition AB, a two-qubit system is different from the previous monogamy inequality that is typically used.
**Results**

This paper is organised as follows: in the first subsection, we recall some basic concepts of concurrence and negativity. We present the monogamy relations of concurrence and negativity in the second subsection. In the third subsection, the generalised monogamy inequalities of CREN are given. The fourth subsection includes some examples that verify these results.

**Preliminaries: concurrence and negativity.** For any bipartite pure state $|\psi\rangle_{AB}$ in a $d \otimes d'$ ($d \leq d'$) quantum system with its Schmidt decomposition,

$$|\psi\rangle_{AB} = \sum_{i=0}^{d-1} \sqrt{\lambda_i} |i\rangle_A |i\rangle_B,$$

the concurrence $C(|\psi\rangle_{AB})$ is defined as

$$C(|\psi\rangle_{AB}) = \sqrt{2(1 - \text{Tr}(|\rho_A^T|^2))},$$

where $\rho_A = \text{tr}_B(|\psi\rangle_{AB}\langle\psi|)$. For any mixed state $\rho_{AB}$, its concurrence is defined as

$$C(\rho_{AB}) = \min_{i} \sum_{j} p_i C(|\psi_i\rangle_{AB}),$$

where the minimum is taken over all possible pure state decompositions $\{|p_i, |\psi_i\rangle_{AB}\}$ of $\rho_{AB}$.

Similarly, the concurrence of assistance (COA) of $\rho_{AB}$ is defined as

$$C_a(\rho_{AB}) = \max_{i} \sum_{j} p_i C(|\psi_i\rangle_{AB}),$$

where the maximum is taken over all possible pure state decompositions $\{|p_i, |\psi_i\rangle_{AB}\}$ of $\rho_{AB}$.

Another well-known quantification of bipartite entanglement is negativity. For any bipartite pure state $|\psi\rangle_{AB}$, the negativity $N(|\psi\rangle_{AB})$ is

$$N(|\psi\rangle_{AB}) = 2\sum_{i<j} \sqrt{\lambda_i \lambda_j} = (\text{Tr}_A(\sqrt{\rho_A^T})^2 - 1,$$

where $\rho_A = \text{tr}_B(|\psi\rangle_{AB}\langle\psi|)$.

For any bipartite state $\rho_{AB}$ in the Hilbert space $\mathcal{H}_A \otimes \mathcal{H}_B$ negativity is defined as

$$N(\rho_{AB}) = \frac{\|\rho_{AB}^T\| - 1}{2},$$

where $\rho_{AB}^T$ is a partial transposition with respect to the subsystem $A$, $\|X\|$ denotes the trace norm of $X$; i.e., $\|X\| = \text{Tr} \sqrt{XX^T}$. Negativity is a computable measure of entanglement, which is a convex function of $\rho_{AB}$. It disappears if, and only if, $\rho_{AB}$ is separable for the $2 \otimes 2$ and $2 \otimes 3$ systems. For the purposes of this discussion, we use the following definition of negativity:

$$N(\rho_{AB}) = \|\rho_{AB}^T\| - 1.$$

For any maximally entangled state in a two-qubit system, this negativity is equal to 1. CREN gives a perfect discrimination of positive partial transposition-bound entangled states and separable states in any bipartite quantum system. For any mixed state $\rho_{AB}$, CREN is defined as

$$N(\rho_{AB}) = \min_{i} \sum_{j} p_i N(|\psi_i\rangle_{AB}),$$

where the minimum is taken over all possible pure state decompositions $\{|p_i, |\psi_i\rangle_{AB}\}$ of $\rho_{AB}$.

For any mixed state $\rho_{AB}$, CRENOA is defined as

$$N_a(\rho_{AB}) = \max_{i} \sum_{j} p_i N(|\psi_i\rangle_{AB}),$$

where the maximum is taken over all possible pure state decompositions $\{|p_i, |\psi_i\rangle_{AB}\}$ of $\rho_{AB}$.

CREN is equivalent to concurrence for any pure state with Schmidt rank-2, and consequently, it follows that for any two-qubit mixed state $\rho_{AB} = \sum_p |\psi\rangle \langle \psi|$, $\rho_{AB}$; and $\rho_{AB}$, it is thus verified that

$$N(\rho_{AB}) = \min \sum p_i N(|\psi_i\rangle_{AB}) = \min \sum p_i C(|\psi_i\rangle_{AB}) = C(\rho_{AB})$$

and

$$N_a(\rho_{AB}) = \max \sum p_i N(|\psi_i\rangle_{AB}) = \max \sum p_i C(|\psi_i\rangle_{AB}) = C_a(\rho_{AB}).$$
where the minimum and the maximum are taken over all pure state decompositions \( \{ \rho_p, |\psi\rangle_{AB} \} \) of \( \rho_{AB} \).

**Monogamy relations of concurrence and negativity.** The CKW inequality\(^8\) was first defined as

\[
C^2(\rho_{ABC}) \geq C^2(\rho_{AB}) + C^2(\rho_{AC}).
\]

(12)

where \( C(\rho_{ABC}) \) is the concurrence of a three-qubit state \( \rho_{ABC} \) for any bipartite cut of subsystems between \( A \) and \( BC \). Similarly, the dual inequality in terms of COA is as follows\(^33\):

\[
C^2(\rho_{ABC}) \leq C^2(\rho_{AB}) + C^2(\rho_{AC}).
\]

(13)

For any pure state \( |\psi\rangle_{A_1...A_n} \) in an \( n \)-qubit system \( A_1 \otimes ... \otimes A_n \) where \( A_i \cong C^2 \) for \( i = 1, ..., n \), a generalisation of the CKW inequality is

\[
C(\rho_{A_1|A_2...A_n}) \geq C^2(\rho_{A_iA_j}) + ... + C^2(\rho_{A_iA_n}).
\]

(14)

The dual inequality in terms of the COA for \( n \)-qubit states has the form\(^17\)

\[
C(\rho_{A_1|A_2...A_n}) \leq C^2(\rho_{A_iA_j}) + ... + C^2(\rho_{A_iA_n}).
\]

(15)

when the rank of the matrix is 2, we have

\[
C(\rho_{A_1|A_2...A_n}) = N(\rho_{A_1|A_2...A_n}).
\]

(16)

Combining Eq. (10) with Eq. (11), we have

\[
\rho_{AB} = \rho_{aAB} + \rho_{BA} + \rho_{CA}.
\]

(17)

where \( i, j \in \{1, ..., n\}, i \neq j \).

For any \( n \)-qubit pure state \( |\psi\rangle_{A_1...A_n} \), we have

\[
N^2(\rho_{A_1|A_2...A_n}) \geq N^2(\rho_{A_iA_j}) + ... + N^2(\rho_{A_iA_n}).
\]

(18)

The dual inequality\(^17\) in terms of CREN is as follows:

\[
N^2(\rho_{A_1|A_2...A_n}) \leq N^2(\rho_{A_iA_j}) + ... + N^2(\rho_{A_iA_n}).
\]

(19)

**Monogamy inequalities of CREN.** For a \( 2 \otimes 2 \otimes m \) quantum pure state \( |\psi\rangle_{ABC} \), it has been shown that

\[
C^2(\rho_{AB}) = C^2(\rho_{AB}) + T^2(|\psi\rangle_{ABC}),
\]

(20)

where \( T^2(|\psi\rangle_{ABC}) = C^2(|\psi\rangle_{ABC}) - C^2(\rho_{AB}) - C^2(\rho_{AC}) \) is the three-tangle of concurrence. \( C(|\psi\rangle_{ABC}) \) is the concurrence under bipartition \( A|BC \) for pure state \( |\psi\rangle_{ABC} \). Namely,

\[
C^2(|\psi\rangle_{A|BC}) = C^2(\rho_{AB}) + C^2(\rho_{AC}).
\]

(21)

The concurrence is related to the linear entropy of a state\(^34\)

\[
T(\rho) = 1 - \text{Tr}(\rho^2).
\]

(22)

Given a bipartite state \( \rho \), \( T(\rho) \) has the property\(^35\),

\[
T(\rho_A) + T(\rho_B) \geq T(\rho_{AB}) \geq ||T(\rho_A) - T(\rho_B)||.
\]

(23)

From the definition of pure state concurrence in Eq. (2) together with Eq. (22), we have

\[
C^2(|\psi\rangle_{AB|C_{1...m-2}}) = 2[1 - \text{Tr}(\rho^2)] = 2T(\rho_{AB}).
\]

(24)

Now, we provide the following theorems:

**Theorem 1.** For any \( 2 \otimes 2 \otimes 2 \) tripartite mixed state \( \rho_{ABC} \), we have

\[
N^2(\rho_{A|BC}) \leq N^2(\rho_{B|AC}) + N^2(\rho_{C|AB}).
\]

(25)

Proof. Let \( \rho_{ABC} = \sum \rho_{p} |\psi_{p}\rangle_{ABC} \) be an optimal decomposition realising \( N(\rho_{ABC}) \); that is,
Theorem 2. For any multi-party mixed state $\rho_{A_1|A_2...A_n}$ in an $n$-qubit system, the following monogamy inequality exists:

$$N_a^2(\rho_{A_1|A_2...A_n}) \leq \sum_{i=2}^{n} N_a^2(\rho_{A_1|A_2...A_i,...A_n}) \leq \sum_{i=2}^{n} \sum_{j=1,j \neq i}^{n} N_a^2(\rho_{A_iA_j}).$$

(31)

The meaning of the first inequality is clear; that is, the sum of the entanglements between $\rho_{A_i}$ and the other qubits, when taken as a group cannot be greater than the sum of the $n-1$ individual bipartite entanglements between $\rho_{A_i}$ and the other remaining qubits. We now start to consider a four-qubit system. As shown in Fig. 1, the squared CRENOA with respect to the bipartition ($A|BCD$) is not greater than the sum of the three squared CRENOAs (the three possible bipartitions are $B|ACD$, $C|ABD$ and $D|ABC$).

The meaning of the second inequality is clear; that is, the sum of the bipartite entanglements between $\rho_{A_i}$ ($i = 1$) and the other remaining qubits cannot be greater than the sum of the bipartite entanglements $\rho_{A_iA_j}$ ($i = 1, j \neq i$).

Theorem 2. For any $n$-qubit pure state $\ket{\psi}_{A_i, B_{i+1}, ..., B_n}$, we have

$$2N_a^2(\rho_{AB}) + \sum_{i=1}^{n-2} N_a^2(\rho_{AC}) + \sum_{i=1}^{n-2} N_a^2(\rho_{BC}) \geq N_a^2(\ket{\psi}_{A_i, B_{i+1}, ..., B_n}).$$

(32)

where $\rho_{AB} = \text{Tr}_{C_{i+1},..,C_n}(\ket{\psi}\bra{\psi})$, $\rho_{AC} = \text{Tr}_{B_{i+1},..,B_n}(\ket{\psi}\bra{\psi})$ and $\rho_{BC} = \text{Tr}_{A_i, C_{i+1},..,C_n}(\ket{\psi}\bra{\psi})$.

Proof. From the result of Theorem 1, we find that the generalised monogamy inequality can be easily obtained by using the superposition of states. We now consider $N_a^2(\ket{\psi}_{A_i, B_{i+1}, ..., B_n})$. When the rank of the matrix is 2, we have

$$N_a^2(\ket{\psi}_{A_i, B_{i+1}, ..., B_n}) = C_a^2(\ket{\psi}_{A_i, B_{i+1}, ..., B_n}) = 2T(\rho_{AB}).$$

(33)
Combining Eq. (23) with Eq. (24), we get the relationship
\[
2T(\rho_{AB}) \leq 2T(\rho_A) + 2T(\rho_B) = C^2(|\psi\rangle_{AB|C_1-c_{c_2}}) + C^2(|\psi\rangle_{B|AC_1-c_{c_2}})
\]
\[
= N^2(|\psi\rangle_{AB|C_1-c_{c_2}}) + N^2(|\psi\rangle_{B|AC_1-c_{c_2}}).
\]
(34)
The third equality follows from the fact that CREN and concurrence are equal for any rank-2 pure state.
\[
N^2(|\psi\rangle_{AB|C_1-c_{c_2}}) \leq N^2(|\psi\rangle_{AB|C_1-c_{c_2}}) + N^2(|\psi\rangle_{B|AC_1-c_{c_2}}). \quad \text{(35)}
\]
For a mixed state, CRENOA is expressed as \( N(\rho_{AB|C_1-c_{c_2}}) \), and we have
\[
N^2(\rho_{AB|C_1-c_{c_2}}) = \max_i p_r N(\rho_{i|AB|C_1-c_{c_2}}).
\]
(36)
Furthermore, when combining this with Eq. (35), we finally get
\[
N^2(|\psi\rangle_{AB|C_1-c_{c_2}}) \leq N^2(\rho_{AB|C_1-c_{c_2}}) + N^2(\rho_{B|AC_1-c_{c_2}}).
\]
(37)
and
\[
N^2(\rho_{AB|C_1-c_{c_2}}) \leq N^2(\rho_{AB}) + \sum_{i=1}^{n-2} N^2(\rho_{AC_i}),
\]
\[
N^2(\rho_{B|AC_1-c_{c_2}}) \leq N^2(\rho_{BC}) + \sum_{i=1}^{n-2} N^2(\rho_{AC_i}). \quad \text{(38)}
\]
Combining Eq. (37) with Eq. (38), we have Eq. (32). In other words, we give an upper bound about \( N^2(|\psi\rangle_{AB|C_1-c_{c_2}}) \), i.e.,
\[
2N^2(\rho_{AB}) + \sum_{i=1}^{n-2} N^2(\rho_{AC_i}) + \sum_{i=1}^{n-2} N^2(\rho_{BC}) \geq N^2(|\psi\rangle_{AB|C_1-c_{c_2}}). \quad \text{(39)}
\]
This completes the proof.

Theorem 2 shows that the entanglement between \( AB \) and the other qubits cannot be greater than the sum of the individual entanglements between \( A \) and each of the \( n-1 \) remaining qubits and the individual entanglements between \( B \) and each of the \( n-1 \) remaining qubits. Theorem 2 provides a polygamy-type upper bound of multi-qubit entanglement between the two-qubit system \( AB \) and the other \((n-2)\)-qubit system \( C_1C_2\ldots C_{n-2} \) in terms of the squared CRENOA. Especially under partition \( AB \), a two-qubit system is different from the previous monogamy inequality. When \( |\psi\rangle_{AB|C_1-c_{c_2}} = |\psi\rangle_A \otimes |\psi\rangle_{B|C_1-c_{c_2}} \), the calculation results in \( N^2(\rho_{AB}) = 0, N^2(\rho_{AC}) = 0 \). Consequently, the polygamy-type relation is obtained as shown in Eq. (19).

Finally, consider the following four-qubit state: \( |\psi\rangle_{ABCD} = a|0100\rangle + b|0010\rangle + c|0001\rangle \) where \( |a|^2 + |b|^2 + |c|^2 = 1 \). We can easily get the following equations: \( N^2(\rho_{AB}) = N^2(\rho_{AC}) = N^2(\rho_{AD}) = 0 \) and \( N^2(\rho_{BC}) + N^2(\rho_{BD}) = N^2(|\psi\rangle_{AB|CD}) = \frac{16}{9} \). Therefore, the state \( |\psi\rangle_{ABCD} \) saturates the monogamy inequality in Eq. (32).

Theorem 3. For any \( n \)-qubit pure state \( |\psi\rangle_{AB,C_1-c_{c_2}} \),
\[
N^2(|\psi\rangle_{AB|C_1-c_{c_2}}) \geq \sum_{i=1}^{n-2} N^2(\rho_{AC_i}) - \sum_{i=1}^{n-2} N^2(\rho_{BC_i}), \quad \text{(40)}
\]
where \( \rho_{AB} = Tr_{C_1-c_{c_2}}(|\psi\rangle\langle\psi|) \), \( \rho_{AC} = Tr_{B|C_1-c_{c_2}C_1-c_{c_2}}(|\psi\rangle\langle\psi|) \) and \( \rho_{BC} = Tr_{A|C_1-c_{c_2}C_1-c_{c_2}}(|\psi\rangle\langle\psi|) \).

Proof. We have the following property for linear entropy \( T \):
\[
T(\rho_{AB}) \geq |T(\rho_A) - T(\rho_B)|. \quad \text{(41)}
\]
Combining Eq. (24) with Eq. (41), we have
\[
2[1 - T(\rho_{AB}^2)] \geq 2[1 - T(\rho_A^2)] - 2[1 - T(\rho_B^2)] \quad \text{(42)}
\]
and
\[
C^2(|\psi\rangle_{AB|C_1-c_{c_2}}) \geq |C^2(|\psi\rangle_{AB|C_1-c_{c_2}}) - C^2(|\psi\rangle_{B|AC_1-c_{c_2}})|. \quad \text{(43)}
\]
By using the equivalent relation between concurrence and CREN (see Eq. (17)), we have
\[
N^2(|\psi\rangle_{AB|C_1-c_{c_2}}) \geq |N^2(|\psi\rangle_{AB|C_1-c_{c_2}}) - N^2(|\psi\rangle_{B|AC_1-c_{c_2}})|. \quad \text{(44)}
\]
There is a relationship between CREN and CRENOA (see Eq. (21)):

\[ N^2(\psi_{A|BC_1...C_{n-2}}) = N^2_a(\rho_{AB}) + N^2_a(\rho_{AC}) \]

Putting the above two equalities into Eq. (44), we get

\[ |N^2_a(\rho_{AB}) - N^2_a(\rho_{BC})| \geq \left| \sum_{i=1}^{n-2} N^2_a(\rho_{AC}) - \sum_{i=1}^{n-2} N^2_a(\rho_{BC}) \right| \]

\[ \geq \left| \sum_{i=1}^{n-2} N^2_a(\rho_{AC}) - \sum_{i=1}^{n-2} N^2_a(\rho_{BC}) \right| \]

(47)

Similar to the above derivation, we give a lower bound about \( N^2(\psi_{AB|C_1...C_{n-2}}) \), i.e.,

\[ N^2(\psi_{AB|C_1...C_{n-2}}) \geq \left| \sum_{i=1}^{n-2} N^2_a(\rho_{AC}) - \sum_{i=1}^{n-2} N^2_a(\rho_{BC}) \right| \]

(48)

This lower bound is a direct consequence of CREN.

Theorem 3 shows that the entanglement between \( AB \) and the other qubits cannot be less than the absolute value of the difference between multi-entanglements between \( A \) and each of the \( n-1 \) remaining qubits and the individual entanglements between \( B \) and each of the \( n-1 \) remaining qubits. Theorem 3 provides a monogamy-type lower bound of multi-qubit entanglement between the two-qubit system \( AB \) and the other \( (n-2) \)-qubit system \( C_1...C_{n-2} \) in terms of the squared CREN. When \( |\psi_{AB|C_1...C_{n-2}} = |\psi_B \rangle \otimes |\psi_{A|C_1...C_{n-2}} \rangle \), \( N^2_a(\rho_{BC}) = 0 \), and so we obtain the CWK-type relation in Eq. (18).

Finally, we consider the following four-qubit state \( |\psi_{ABCD} = a|1000 \rangle + b|0110 \rangle + c|0001 \rangle \) where \( |a|^2 + |b|^2 + |c|^2 = 1 \), from which we can easily obtain the following equations: \( N^2_a(\rho_{BC}) = N^2_a(\rho_{BD}) = 0 \) and \( N^2_a(\rho_{AC}) + N^2_a(\rho_{AD}) = N^2(\rho_{ABCD}) = \frac{16}{3} \). Therefore, the state \( |\psi_{ABCD} \) saturates the monogamy inequality in Eq. (40). Therefore, a generalised monogamy inequality using negativity and CRENOA in an \( n \)-qubit is proposed. These relations also give rise to a type of trade-off in inequalities that is related to the upper and lower bounds of CRENOA.

Remark. It is interesting to note that the properties of CREN are based on the subadditivity of linear entropy. However, negativity violates this subadditivity in general conditions.\(^{37-39}\)

**Examples.** In this section, we use some special states to study generalised monogamy inequalities. First, we consider the (Greenberger-Horne-Zeilinger) GHZ state and W state in Examples 1 and 2. Second, we consider two states in the higher-dimensional system in Examples 3 and 4.

**Example 1.** For an arbitrary pure GHZ state in an \( n \)-qubit system:

\[ |\text{GHZ} \rangle = a|0\rangle^{\otimes n} + b|1\rangle^{\otimes n}, \]

where \( |a|^2 + |b|^2 = 1 \). The generalised GHZ state is satisfied with the previous CKW inequality. We will now show that the generalised GHZ state satisfies the generalised monogamy inequalities. We have \( \rho_1 = \rho_2 = ... = \rho_n = a^2|0\rangle \langle 0| + b^2|1\rangle \langle 1| \). It is straightforward to check:

\[ N^2_a(\rho_{A|B_1...B_{n-2}}) = N^2_a(\rho_{A|C_1...C_{n-2}}) = 4|ab|^2 \]

\[ N^2_a(\rho_{A|C_1...C_{n-2}}) = 4|ab|^2 \]

Therefore:

\[ \sum_{i=2}^{n-2} N^2_a(\rho_{A|B_1...B_{n-2}}) = 4|ab|^2 \]

(50)

\[ 2N^2_a(\rho_{AB}) + \sum_{i=1}^{n-2} N^2_a(\rho_{AC}) + \sum_{i=1}^{n-2} N^2_a(\rho_{BC}) = 8(n-1)|ab|^2 \]

(51)

\[ N^2(\psi_{AB|C_1...C_{n-2}}) = 4|ab|^2 \]

(52)

**Example 2.** For a pure state \( |W \rangle \) in an \( n \)-qubit system:

\[ |W \rangle = \frac{1}{\sqrt{n}} (|10...0\rangle + |01...0\rangle + ... + |00...1\rangle) \]

with \( \sum_{i=1}^{n-1} |\frac{1}{\sqrt{n}}|^2 = 1 \). It is very important to understand the saturation of the previous CKW inequality. Using a simple calculation, we have \( \rho_1 = \rho_2 = ... = \rho_n = \frac{1}{n}|1\rangle \langle 1| + \frac{n-1}{n}(|0\rangle \langle 0| \). It is straightforward to check.
\[ N^2(\rho_{A_1|A_{2\ldots A_n}}) = N^2(\rho_{A_1|A_{2\ldots A_{n-1}A_1A_{n-1}}} = \ldots = N^2(\rho_{A_1|A_1A_2A_{n-1}A_{n-2}}) = \frac{4(4-1)}{n^2} = \frac{8(n-2)}{n^2}. \]

In the same way, we get the following inequalities:

\[ N^2(\rho_{A_1|A_{2\ldots A_n}}) = \frac{4(n-1)}{n^2} \leq \frac{4(n-1)^2}{n^2} = \sum_{i=2}^{n} N^2(\rho_{A_i|A_{1\ldots A_{i-1}A_{i+1}\ldots A_n}}), \]

\[ 2N^2(\rho_{AB}) + n^2 - 2 = \sum_{i=1}^{n-2} N^2(\rho_{AC}) + \sum_{i=1}^{n-2} N^2(\rho_{BC}) = \frac{8(n-1)}{n^2} \geq \frac{8(n-2)}{n^2} = N^2(|\psi\rangle_{AB}|C_1 \ldots C_{n-2}). \]

\[ N^2(|\psi\rangle_{AB}|C_1 \ldots C_{n-2}) = \frac{8(n-2)}{n^2} \geq 0 = \left[ \sum_{i=1}^{n-2} N^2(\rho_{AC}) - \sum_{i=1}^{n-2} N^2(\rho_{BC}) \right]. \]

From the above results, we discover that the generalised GHZ state and W state satisfy our inequalities. We further explore the condition of the generalised inequalities in higher-dimensional systems. We consider the following examples:

Example 3. For a pure, totally antisymmetric state \(|\psi_{ABC}\rangle\) in a 3 \(\otimes\) 3 \(\otimes\) 3 system:

\[ |\psi_{ABC}\rangle = \frac{1}{\sqrt{6}}(|123\rangle - |132\rangle + |231\rangle - |213\rangle + |312\rangle - |321\rangle). \]

This special quantum state is not satisfied with the previous CKW inequality\(^{41}\) but is established in generalised monogamy inequalities. We can easily obtain \(N^2(\rho_{ABC}) = N^2(\rho_{ABA}) = N^2(\rho_{CAB}) = 4\) and further obtain the inequalities \(N^2(\rho_{ABC}) \leq N^2(\rho_{ABA}) + N^2(\rho_{CAB})\). We now explore examples 2 and 3. First, we have \(N^2(\rho_{AB}) = 4N^2(\rho_{AC}) = 4N^2(\rho_{BC}) = 4\). Therefore, we obtain the following inequalities:

\[ 2N^2(\rho_{AB}) + n^2 - 2 = \sum_{i=1}^{n-2} N^2(\rho_{AC}) + \sum_{i=1}^{n-2} N^2(\rho_{BC}) \geq 4N^2(\rho_{AC}) - 4N^2(\rho_{BC})\].

Example 4. The \(n\)-qudit generalised W-class state in higher-dimensional quantum systems is very useful in quantum information theory\(^{42}\). We verify whether the generalised monogamy inequalities hold in higher-dimensional systems using a special example. First, we recall the definition of \(n\)-qudit generalised W-class state\(^{43}\):

\[ |W_{AB}^{d}\rangle_{A_1\ldots A_n} = \sum_{i=1}^{d-1} |a_i\rangle_0 |0 \ldots 0\rangle + a_{d-1} |1 \ldots 0\rangle + \ldots + a_{n-1} |0 \ldots 0\rangle. \]

where \(\sum_{i=1}^{d-1} |a_i\rangle_0 = 1\).

Let \(|\psi\rangle_{A_1\ldots A_n}\) be an \(n\)-qudit pure state in a superposition of an \(n\)-qudit generalised W-class state and vacuum; that is,

\[ |\psi\rangle_{A_1\ldots A_n} = \sqrt{p} |W_{AB}^{d}\rangle_{A_1\ldots A_n} + \sqrt{1-p} |0 \ldots 0\rangle_{A_1\ldots A_n}, \]

for some \(0 \leq p \leq 1\).

For the squared negativity \(N^2\) of \(|\psi\rangle_{A_1\ldots A_n}\) with respect to the bipartition between \(A_1\) and the other qudits, the reduced density matrix \(\rho_{A_1}\) of \(|\psi\rangle_{A_1\ldots A_n}\) onto subsystem \(A_1\) is obtained as

\[ \rho_{A_1} = \text{Tr}_{A_2 \ldots A_n} |\psi\rangle_{A_1\ldots A_n} \langle \psi| = p \sum_{i=1}^{d-1} a_i a_i^\dagger |i\rangle_{A_1} \langle i| + |p\Omega + (1-p)|0\rangle_{A_1} \langle 0| + \sqrt{p(1-p)} \times \left[ \sum_{i=1}^{d-1} a_i |i\rangle_{A_1} \langle i| + \sum_{j=1}^{d-1} a_j^\dagger \langle j|_{A_1} \right], \]

where \(\Omega = \sum_{i=1}^{n} \sum_{j=1}^{d-1} |a_i|^2 = 1 - \sum_{j=1}^{d-1} |a_j|^2\).

When considering the \(|\psi\rangle_{A_1\ldots A_n}\) state, we need to obtain the eigenvalue of the matrix by applying the definition of pure state negativity in Eq. (5). Using a simple calculation, we find that the matrix has rank-2 and we have

\[ N^2(|\psi\rangle_{A_1\ldots A_n}) = \left[ \text{Tr} \sqrt{\rho_{A_1}} \right]^2 - 1 = 4A_1 \lambda_j = 4p^2(1-\Omega)\Omega. \]
\[
\rho_{A_1A_2} = \text{Tr}_{A_3 \cdots A_n} |\psi\rangle_{A_1A_2 \cdots A_n} \langle \psi|
\]
\[
= p \sum_{i,j=1}^{d-1} \left( a_{ij} |0\rangle_{A_iA_j} \langle 0| + a_{ij}^* |0\rangle_{A_iA_j} \langle 0| \right) + a_{ij} a_{ij}^* |0\rangle_{A_iA_j} \langle 0| \\
+ a_{ij} a_{ij}^* \langle 0|_{A_iA_j} \rangle_{A_iA_j} \langle 0| + \sqrt{p(1-p)} \sum_{i,j=1}^{d-1} \left( a_{ij} |0\rangle_{A_iA_j} \langle 0| + a_{ij}^* |0\rangle_{A_iA_j} \langle 0| \right) \\
\times \sum_{i,j=1}^{d-1} \left( a_{ij} |0\rangle_{A_iA_j} \langle 0| + a_{ij}^* |0\rangle_{A_iA_j} \langle 0| \right) + \langle 0|_{A_iA_j} \rangle_{A_iA_j} \langle 0|_{A_iA_j} \rangle_{A_iA_j} \langle 0| \\
\times \sum_{i,j=1}^{d-1} \left( a_{ij} |0\rangle_{A_iA_j} \langle 0| + a_{ij}^* |0\rangle_{A_iA_j} \langle 0| \right) + \langle 0|_{A_iA_j} \rangle_{A_iA_j} \langle 0| + a_{ij}^* |0\rangle_{A_iA_j} \langle 0| + a_{ij}^* \langle 0|_{A_iA_j} \rangle_{A_iA_j} \langle 0| \right) \\
(63)
\]

where \( \Omega_2 = 1 - \sum_{j=1}^{d-1} \left( a_{ij}^2 + a_{ij}^2 \right) \). For convenient calculation, we consider two unnormalised states:

\[
[\bar{\rho}] = \sqrt{p} \sum_{i=1}^{d-1} \left( a_{ii} |0\rangle_{A_iA_j} + a_{ii} |0\rangle_{A_iA_j} \right) + \sqrt{1-p} \langle 0|_{A_iA_j} \rangle_{A_iA_j}, \quad [\bar{\rho}] = \sqrt{\Omega_2} |0\rangle_{A_iA_j} \langle 0|_{A_iA_j}.
\]

(64)

Consequently, \( \rho_{A_1A_2} \) can be represented as \( \rho_{A_1A_2} = [\bar{\rho}]_{A_1A_2} \rho_{A_2A_1} [\bar{\rho}]_{A_1A_2} \), where \( \bar{\rho} \) and \( \bar{\rho} \) are unnormalised states of the subsystems \( A_1 \) and \( A_2 \). By the HJW theorem, any pure-state decomposition \( \rho = \sum_{i=1}^{d-1} \rho_{A_iA_j} \) with size \( r > 2 \) can be obtained by an \( r \times r \) unitary matrix \( \mathcal{U}_{dl} \) such that

\[
\rho_{A_1A_2} = \mathcal{U}_{dl} |\bar{\rho}\rangle_{A_1A_2} \langle \bar{\rho}|_{A_1A_2} \mathcal{U}_{dl}^\dagger,
\]

(65)

for each \( h \), for the normalized state \( |\psi_h\rangle_{A_1A_2} = |\bar{\psi}_h\rangle_{A_1A_2} / \left\| |\bar{\psi}_h\rangle_{A_1A_2} \right\| \)

We apply the definition of mixed state negativity in Eqs (8 and 63), and then we have the two-tangle based on the CREN of \( \rho_{A_1A_2} \) as

\[
N^2_\text{CREN}(\rho_{A_1A_2}) = \min_i p_i N^2(\rho_{A_1A_2}^{(i)}) = 4p^2(1 - \Omega) \sum_{i=1}^{d-1} |a_{ii}|^2 = 4p^2(1 - \Omega) \Omega',
\]

(66)

where \( \Omega' = \sum_{i=2}^{d-1} |a_{ii}|^2 / |a_{ii}|^2 \).

From the definition of pure state negativity in Eqs (9 and 63), we have

\[
N^2_\text{CREN}(\rho_{A_1A_2}) = \min_i p_i N^2(\rho_{A_1A_2}^{(i)}) = 4p^2(1 - \Omega) \Omega',
\]

(67)

We now try to verify the generalised monogamy inequalities of CREN in an \( n \)-qudit system. For convenient calculation, we assume that \( \sum_{i=1}^{d-1} a_{ii}^2 = a, \sum_{i=1}^{d-1} a_{ii}^2 = b \), \( \sum_{i=1}^{d-1} a_{ii}^4 = A \), \( \sum_{i=1}^{d-1} a_{ii}^4 = B \).

We first consider the generalisation of Theorem 1.

\[
N^2_\text{CREN}(\rho_{A_1A_2}) = N^2_\text{CREN}(\rho_{A_1A_2}) = \cdots = N^2_\text{CREN}(\rho_{A_1A_2}) = 4p^2(1 - \Omega) \Omega = 4p^2(1 - a).
\]

(68)

This special quantum state is satisfied with the generalised monogamy inequality in Eq. (25) i.e.,

\[
N^2_\text{CREN}(\rho_{A_1A_2}) \leq \sum_{i=2}^{n} N^2_\text{CREN}(\rho_{A_1A_2}),
\]

(69)

For the generalisation of Theorem 2, the left of Eq. (32) is

\[
2N^2_\text{CREN}(\rho_{AB}) + \sum_{i=1}^{n-2} N^2_\text{CREN}(\rho_{AC_i}) + \sum_{i=1}^{n-2} N^2_\text{CREN}(\rho_{BC_i}).
\]

(70)

Using Eqs (8 and 62) we can simplify the calculation to

\[
N^2_\text{CREN}(\rho_{AB}) + \sum_{i=1}^{n-2} N^2_\text{CREN}(\rho_{AC_i}) = N^2_\text{CREN}(\rho_{AC_{n-1}C_n}) = 4p^2(1 - \Omega) \Omega = 4p^2(1 - a)
\]

(71)

and

\[
\sum_{i=1}^{n-2} N^2_\text{CREN}(\rho_{BC_i}) = N^2_\text{CREN}(\rho_{BC_{n-1}C_n}) = 4p^2(1 - b) \Omega = 4p^2(1 - b).
\]

(72)

After some calculations, we have
2N^2_A(p_{AB}) + \sum_{i=1}^{n-2} N^2_A(p_{AC}) + \sum_{i=1}^{n-2} N^2_B(p_{BC}) = N^2_A(p_{AB}) + \sum_{i=1}^{n-2} N^2_A(p_{AC}) + N^2_B(p_{BC}) + \sum_{i=1}^{n-2} N^2_A(p_{AC}) + N^2_B(p_{BC}) = 4p^2(1-a) + 4p^2(1-b) + 4p^2ab. \tag{73}

Second, taking Eq. (67) to the right side of Eq. (32), we then have

\[ N^2(\langle\psi\rangle_{AB|C_{1}...C_{n-2}}) = 4p\Omega_1(1 - \Omega_2) = 4p^2[1 - (a + b)](a + b). \tag{74} \]

After a straightforward calculation, we obtain

\[ 2N^2_A(p_{AB}) + \sum_{i=1}^{n-2} N^2_A(p_{AC}) - \sum_{i=1}^{n-2} N^2_B(p_{BC}) - N^2(\langle\psi\rangle_{AB|C_{1}...C_{n-2}}) = 12p^2ab \geq 0. \tag{75} \]

Therefore, this \( n \)-qubit pure state is satisfied with the generalised monogamy inequality in Eq. (40). In other words, the test of the Theorem 2 has been accomplished. Next, we verify Theorem 3. First, we consider the term CREN from Eq. (40):

\[ \sum_{i=1}^{n-2} N^2_A(p_{AC}) = N^2_A(p_{ABC|C_{n-2}}) - N^2_A(p_{AB}) = 4p^2(1 - \Omega)\Omega - 4p^2(1 - \Omega)\Omega' = 4p^2a(1 - a - b). \tag{76} \]

Calculating the absolute value of the difference between Eqs (72 and 76), we obtain

\[ \left| \sum_{i=1}^{n-2} N^2_A(p_{AC}) - \sum_{i=1}^{n-2} N^2_B(p_{BC}) \right| = 4p^2(a - a^2 - ab + b^2 - b). \tag{77} \]

It is easy to check \( 4p^2(a - a^2 - ab + b^2 - b) > 0 \), as

\[ 0 \leq a + b \leq 1 \Rightarrow a(a + b) \leq a \Rightarrow a^2 + ab - b < a(a + b) \leq a \Rightarrow a^2 + ab - b + b^2 - a < 0 \Rightarrow a - a^2 - ab + b^2 - b > 0 \Rightarrow 4p^2(a - a^2 - ab + b^2 - b) > 0. \tag{78} \]

After a straightforward calculation, we have

\[ N^2(\langle\psi\rangle_{AB|C_{1}...C_{n-2}}) - \sum_{i=1}^{n-2} N^2_A(p_{AC}) - \sum_{i=1}^{n-2} N^2_B(p_{BC}) \right| = 4p^2b(2 - 2b - a) \geq 0. \tag{79} \]

Therefore, this \( n \)-qubit pure state satisfies the generalised monogamy inequality in Eq. (40). We have now verified the generalised monogamy inequalities. In other words, the generalised monogamy inequality are satisfied with the \( n \)-qubit pure state for all three of our theorems.

**Conclusions**

In this paper, we have used CREN to study different types of monogamy relations. In particular, we have shown that CREN satisfies the generalised monogamy inequalities. We have investigated the CKW-like inequalities and generalised monogamy inequalities. Furthermore, the generalised monogamy inequalities related to CREN and CRENOA were obtained by \( n \)-qubit states. These relations also give rise to a type of trade-off in inequalities that is related to the upper and lower bounds of CRENOA. Finally, we have shown that the partially coherent superposition of the generalised W-class state and vacuum extensions of CREN satisfies the generalised monogamy inequalities. We believe that the generalised monogamy inequalities can be useful in quantum information theory. This paper was based on the linear entropy. To continue this work, we will study the nature of other entropy further in the future work. We hope that our work will be useful to the quantum physics.
