samples from the local community were positive for SFG, and 4.3% (1/23) were positive for TG (Appendix Table 1), indicating a high seroprevalence of SFG and co-circulation of TG in the region.

Because of the treating physicians’ unawareness of the prevalence of rickettsioses, the patient’s illness was misdiagnosed and incorrectly treated. In light of the fatal cases of *R. sibirica* subsp. *sibirica* infection recently documented in Russia and China (8–10), our report highlights the risk for rickettsial diseases among the public in the Qinghai–Tibet Plateau region and the urgent need for a large-scale seroepidemiologic survey.

**Eosinophilic Meningitis and Intraocular Infection Caused by *Dirofilaria* sp. Genotype Hongkong**

Eosinophilic meningitis caused by human dirofilarial infection is rare. We report a case of eosinophilic meningitis and concomitant intraocular dirofilarial infection in India. Sequencing of the mitochondrial genome identified the worm as *Dirofilaria* sp. genotype Hongkong, a close relative of *D. repens* nematodes.
Dirofilaria is a group of mosquitoborne parasitoses. The most prevalent Dirofilaria species causing infection are *D. imitis* and *D. repens* nematodes (1). Dogs are the definitive hosts in the life cycle, in which microfilaremia is observed. Humans are aberrant hosts, and the worms usually remain infertile (1,2). Human dirofilariaisis is reported mostly as 1 worm in the subconjunctival or subcutaneous spaces. Surgical extraction of the worm constitutes definitive therapy. These worms are rarely observed inside the eye (1,2). Identification of the worm by using morphologic features is difficult because a large number of *Dirofilaria* species have similar features.

Diagnosis of eosinophilic meningitis is based mainly on clinical features and microscopic identification of eosinophils in the central nervous system. Helminthic infections, such as angiostrongylosis, baylisascariasis, and gnathostomiasis, are most commonly implicated in eosinophilic meningitis (3). We report a rare case of eosinophilic meningitis and concomitant intraocular dirofilarial infection. Sequencing of the mitochondrial genome of the extracted worm identified it as *Dirofilaria* sp. genotype Hongkong, a close relative of *D. repens* (4).

A 17-year-old woman came to our institute in Kochi, India, because of acute onset of severe headache, irritability, visual blurring, and diplopia, after 3 weeks of intermittent fever. She had meningeal signs, bilateral lateral rectus palsy, and papilledema. Peripheral eosinophilia (14.2%) was observed. Magnetic resonance imaging of the brain (Appendix Figure 1, https://wwwnceid.cdc.gov/EID/article/27/5/20-3599-App1.pdf) showed diffuse leptomeningeal enhancement. Cerebrospinal fluid showed lymphocytic pleocytosis (1,040 cells/µL), major eosinophilia (37%), and protein and glucose levels within reference ranges.

![Figure](https://wwwnceid.cdc.gov/EID/article/27/5/20-3599-App1.pdf)

**Figure.** Eosinophilic meningitis and intraocular infection caused by *Dirofilaria* sp. genotype Hongkong in a patient in Kochi, India. A) Organism (arrow) in the left eye of patient during routine clinical examination. The organism caused an abnormal shape of the pupil. B) Live worm (arrow) in anterior chamber of the left eye. This image was obtained while lignocaine was being injected. C) Gross specimen of the worm (arrow) after extraction. Worm is in saline in a Petri dish.
isolate was performed by using the maximum-likelihood method with 1,000 bootstrap replications and MEGA X version 7 (https://www.megasoftware.net). Both the 12S rRNA and the COX1 sequences obtained from the human isolate were in the same cluster with *Dirofilaria* sp. genotype Hongkong and were separated from other *Dirofilaria* species (5,6) (Appendix Figure 2). Peripheral blood smears were negative for microfilaria. Symptoms of the patient resolved slowly after worm extraction and initiation of treatment with steroids.

Migrating worms in humans might cause a variety of clinical problems, which could be caused by mechanical effects or immune responses. Intraocular parasites might induce severe damage to various structures in the eye. Literature on eosinophilic meningitis and concomitant ocular parasites is limited. Clinical manifestations of eosinophilic meningitis are usually attributed to the severe inflammatory response incited by migrating worms, even though they are rarely demonstrated in vivo. Eosinophilic meningitis caused by *Angiostrongylus cantonensis* worms has been frequently reported in the Asia–Pacific region (7). *Dirofilaria* infection rarely results in eosinophilic meningitis (1,2).

Poppert et al. reported a case of *D. repens* infection, which was subsequently identified as *Dirofilaria* sp. genotype Hongkong, which caused subcutaneous infection and concomitant eosinophilic meningoencephalitis in a traveler returning from Kerala, India, and Sri Lanka to Germany (8). Subconjunctival infection with *Dirofilaria* sp. genotype Hongkong has also been reported in a patient returning to Austria after a 7-week stay in India (9). A recent study from Kerala, India, suggested that most of *D. repens* infections reported from southern India have the *Dirofilaria* sp. Hongkong genotype (10).

Demonstration of a live, intraocular worm and its subsequent identification as *Dirofilaria* sp. genotype Hongkong by using sequencing added a new dimension to this case of eosinophilic meningitis. Infection with the *Dirofilaria* sp. Hongkong genotype, blood eosinophilia, and eosinophilic meningitis are the 3 strikingly similar features between our case-patient and Poppert et al. (8), suggesting that *Dirofilaria* sp. genotype Hongkong might induce a more systemic eosinophilic reaction than *D. repens*.

Sequencing using panfilarial primers might help characterize most filarial species. Such an approach might clarify the etiopathogenesis of eosinophilic meningitis, leading to newer therapeutic and preventive strategies.

### About the Author

Dr. Jyotsna is a resident in pediatric neurology at Amrita Institute of Medical Sciences and Research Centre, Kochi, Kerala, India. Her primary research interest is neurologic manifestations of infectious diseases.
