**Objectives:** We examined the effects of a mixed formula consisting of dried pomegranate concentrate powder (PCP) and the aqueous extracts of \textit{Eucommiae cortex} (EC) and \textit{Achyranthis radix} (AR) in rats with surgically induced osteoarthritis (OA).

**Methods:** Two weeks after OA-inducing surgery, a PCP:EC:AR 5:4:1 (g/g) combination or single formula was orally administered. Changes in body weight, knee thickness, maximum knee extension angle, bone mineral density of the knee joints, femoral and tibial articular surfaces, and compressive strength of the femoral and tibial articular cartilage (AC) were assessed, along with the prostaglandin E2 level, 5-lipoxygenase, matrix metalloproteinase (MMP)-2 and MMP-9 activity, and chondrogenic gene mRNA expression in the femoral and tibial AC with the synovial membrane (SM). In addition, the number of cleaved poly(ADP-ribose) polymerase, cyclooxygenase and tumor necrosis factor-\(\alpha\)-immunoreactive cells in the femoral and tibial AC with SM were monitored, and the rate of cell proliferation was determined with a 5-bromo-2'-deoxyuridine uptake assay.

**Results:** The signs of surgically induced OA in rats were significantly inhibited by both PCP, EC and AR combined and single formulas. In particular, the combination formula-treated OA model rats showed dose-dependent, significantly increased inhibitory activity against all tested criteria compared with single formula-treated rats.

**Conclusions:** Taken together, our results suggest that the combination formula synergistically increased the anti-OA effects of its components through anti-inflammatory and chondrogenic activity in rats with surgically induced OA. In addition, 200, 100 and 50 mg/kg combination formula treatments showed dose-dependent inhibitory activity against all of the tested criteria.

**Key Words:** Dried pomegranate concentrate powder, \textit{Eucommiae Cortex}, \textit{Achyranthis Radix}, PCP:EC:AR 5:4:1 (g/g) mixed formulation, Efficacy confirmation, Surgically induced osteoarthritic rats
Anti-osteoarthritic effects of a combination of pomegranate concentrate powder, Eucommiae cortex and Achyranthis radix in rats

Introduction

Osteoarthritis (OA) occurs when the function and structure of articulation is altered by age and injury; it is the most common joint disease in the elderly. Aging is considered an important factor in the development of OA because the inevitable repetitive loading or injury of articular cartilage (AC) leads to increased regeneration, which consequently causes cartilage degeneration. The expression of pro-inflammatory cytokines, such as interleukin (IL)-1, IL-6, IL-18 and tumor necrosis factor-α (TNF-α) increase proportionally with age; they stimulate cartilage resorption and inhibit the synthesis of new matrix components in articular tissue. These inflammatory OA pathways can be induced by impaired autophagy, oxidative stress, failure to clear apoptotic bodies and protein misfolding.

AC is a complex structure composed of chondrocytes and the extracellular matrix (ECM), including collagen, proteoglycans (PGs), aggrecan and SRY-box 9 (SOX9). Changes in the ECM induce the pathogenesis of OA. Once AC is damaged by physical forces, it loses PGs and undergoes swelling and hypertrophy. When chondrocytes recognize changes in the ECM to synthesize matrix molecules, chondrocytes increase and produce nitric oxide, which activates cytokines. In addition, IL-1 and TNF-α stimulate the production of prostaglandin E2 (PGE2) by inducing the expression of cyclooxygenase-2 (COX-2) and soluble phospholipase A2. As the balance between the synthesis and degradation of chondrocytes is an important factor in the maintenance of AC, the disruption of this process results in the progressive thinning of the AC. The expression of matrix metalloproteinases (MMPs) also participates in the degradation of collagens, and ultimately, the disruption of fibril function. The thinning and destruction of the AC results in the clinical symptoms of joint pain and loss of joint function.

Because the number of older people is increasing worldwide, the prevalence of OA is expected to increase. Thus, there is an urgent need to develop disease-modifying OA drugs for patients suffering from OA. Nonsteroidal anti-inflammatory drugs (NSAIDs), analgesics, and hyaluronic acid have been used to slow the progression of OA, but have no overt disease-modifying effects. NSAIDs may even exacerbate the progression of OA, and these effects are likely due to the suppression of the synthesis of PG, a key component in the formation and function of cartilage. Our group has been exploring agents with protective effects against OA, including natural products, medicinal foods and mixed formulations, to determine whether they exhibit potent anti-arthritic effects.

Pomegranates have a high fiber, pectin and tannin content, and contain flavonoids and anthocyanins in their seed oil and juice. Furthermore, powerful antioxidant and anti-inflammatory effects of pomegranate on chondrocytes have been identified; our previous studies demonstrated that pomegranate has various biological activities such as antioxidant and anti-inflammatory effects. These protective effects have caused pomegranate products to become increasingly popular worldwide. Eucommiae cortex (EC) has been used in the protection of the liver and kidneys, and the treatment of hypertension, inflammation and viral infection in traditional Korean medicine. In particular, EC as a component of a mixture has been demonstrated to promote anti-arthritic properties. Achyranthis radix (AR) has been used extensively in the treatment of osteodynia of the lumbar region and knees, as well as flaccidity and spasms of the limbs. Several previous studies have demonstrated the anti-arthritic properties of AR through in vivo and...
As mixed formulations of medicinal agents may have synergistic biological activity from the diversity of their ingredients\(^{19,31-34}\), we expected that appropriately mixed formulations of pomegranate concentrate powder (PCP), EC and AR could be potent alternative agents to treat OA. The results of our previous in vitro study\(^{35}\) suggested that a mixed formulation of PCP with appropriate proportions of EC and AR induced potent synergistic effects. Based on these results, an in vivo study was performed to select the appropriate proportions among the nine types of formulations consisting of PCP with AR and EC. As a result, a PCP:AR:EC 5:4:1 (g/g) combination was selected as the best, showing evident synergistic anti-OA potential compared with equal dosages of each single formula (PCP, EC or AR)\(^{36}\). However, the previous in vivo study was insufficient to obtain information regarding the PCP:AR:EC 5:4:1 (g/g) combination because the objective was focused on determining the appropriate proportion of the treatments. Thus, this study examined the dose-dependent effects of several doses of the PCP:AR:EC 5:4:1 (g/g) combination in rats with surgically induced OA through an anterior cruciate ligament transection and partial medial meniscectomy. The expression levels of PGE\(_2\), 5-lipoxygenase (LPO), MMP-2, and MMP-9 were observed in rats with surgically induced OA concomitant with the transcript levels of chondrogenic genes. Knee thickness and the maximum extension angles of each knee were analyzed, along with the numbers of cleaved poly(ADP-ribose) polymerase (PARP), COX-2 and TNF-\(\alpha\)-immunoreactive cells in the femoral and tibial AC with the synovial membrane (SM).

### Materials and methods

#### Animals and husbandry

A total of 105 healthy male SPF/VAF outbred rats and Crl:CD1[Sprague-Dawley] rats (6-week old, 150–180 g upon receipt; OrientBio, Seungnam, Korea) were used after acclimatization for 8 days. The rats were maintained at 20-25°C and 45-55% humidity. The light-dark cycle was 12L:12D; feed and water were supplied ad libitum. Ninety rats underwent the surgical induction of OA, in the following treatment groups: OA control (orally administered distilled water), diclofenac group (2 mg/kg subcutaneous diclofenac sodium), PCP group (orally administered 200 mg/kg PCP), EC group (orally administered 200 mg/kg EC), AR group (orally administered 200 mg/kg AR), 200 mg/kg group (orally administered 200 mg/kg PCP:EC:AR mixed formula), 100 mg/kg group (orally administered 100 mg/kg PCP:EC:AR mixed formula) and 50 mg/kg group (orally administered 50 mg/kg PCP:EC:AR mixed formula). 15 rats were sham-operated control rats, receiving orally administered distilled water. All of the laboratory animals were treated according to internationally accepted regulations.

Approval by the Institutional Animal Care and Use Committee of Daegu Haany University (Gyeongsan, Gyeongbuk, Korea) was obtained prior to all animal experiments [Approval No., DHU2015-051].

#### Preparation and administration of test substances

PCP contained the active ingredient, 1.15 mg/g ellagic acid. The EC extracts (containing 1.62 mg/g pinoresinol diglucoside) and AR extracts (containing 0.25 mg/g ecdysterone) were prepared and supplied by HL Science Co., Ltd. (Uiwang-si, Gyeonggi-do, Korea). All test materials were stored at 4°C and protected against light and moisture. A dose level of
Anti-osteoarthritic effects of a combination of pomegranate concentrate powder, *Eucommiae cortex* and *Achyranthis radix* in rats

200 mg/kg was selected as the highest dose of the mixed formula consisting of PCP:EC:AR 5:4:1 (g/g) as requested by the sponsor based on the highest possible clinical dosage in humans. The 100 and 50 mg/kg doses were selected as the middle and lowest doses by reducing the initial dose by a factor of 2. The doses of each single herbal extract (PCP, EC and AR) were also administered at 200 mg/kg to directly compare the potential synergistic effects with the mixed formula.

The PCP:EC:AR 5:4:1 (g/g) mixed formula at doses of 200, 100, and 50 mg/kg, or 200 mg/kg PCP, EC or AR were dissolved in distilled water at 5 mL/kg and orally administered once daily for 58 days beginning 2 weeks after OA surgery. 2 mg diclofenac was dissolved in 5 mL sterile saline and subcutaneously administered on the dorsal back skin at a volume of 5 mL/kg, equivalent to 2 mg/kg, daily for 58 days beginning 14 days after OA surgery. Each single formula of PCP, EC and AR was prepared by dissolving 200 mg in 5 mL distilled water, after which it was orally administered in a volume of 5 mL/kg, equivalent to 200 mg/kg, as in our previous study. The PCP:EC:AR 5:4:1 (g/g) mixed formula was prepared by directly dissolving 100, 80 and 20 mg PCP, EC and AR in 5 mL distilled water for the highest dosage; 50, 40 and 10 mg for the middle dosage, or 25, 20, and 5 mg for the lowest dosage; this was orally administered in a volume of 5 mL/kg, equivalent to 200, 100, and 50 mg/kg, respectively. Equal volumes of vehicle (distilled water) were orally administered to the sham and OA control rats. Formulations of test substances were prepared weekly and stored at 4°C until use.

OA induction by anterior cruciate ligament transection and partial medial meniscectomy

Ten rats per group were allocated (selected) according to variations in body weight and knee thickness at 6 days after OA surgery. Isoflurane (2-3% for induction, 1-1.5% for maintenance; Hana Pharm. Co., Hwasung, Korea) in a mixture of N₂O and O₂ was used for anesthesia with an inhalation anesthesia apparatus (Surgivet, Waukesha, WI, USA) and a ventilator (Model 687, Harvard Apparatus, Cambridge, UK). The OA induction group received surgery including anterior cruciate ligament transection and partial medial meniscectomy through an incision on the medial aspect of the joint capsule, in front of the medial collateral ligament. Then the incision was sutured in two layers. The joint capsule was closed separately from the peripheral tissue using dissolving 5-0 Vicryl sutures, and the skin was closed with interrupted silk sutures. The operated side was used as OA induced side; the other side (non-operated, intact side) was designated as the contralateral side. A similar operation was performed in the sham operated group, except for the anterior cruciate ligament transection and partial medial meniscectomy, according to the method described above.

Body weight measurements

The body weights of rats were recorded once per week using an electronic balance. The rats were sacrificed at 24 h after the last administration of treatment. Rats were fasted overnight for ~18 h prior to surgery for reducing the risk of the anaesthesia-related pulmonary aspiration, but were provided with free access to water.

Measurements of knee thickness

At 6 days after the surgical induction of OA, on the day of initial administration, and at 1, 7, 14, 21, 28, 35, 42, 49, 57 and 58 days after treatment, the knee thickness was observed in the OA-operated hind knees using digital calipers (Mytutoyo, Tokyo, Japan) with the joint capsule exposed to minimize the
differences from surrounding tissues. Knee thickness was also measured at sacrifice.

**Determination of the maximum extension angle of the knees**

After sacrifice, the region between the coxofemoral joint and ankle was dissected in OA-induced knees, while the intact articular capsule was excluded. Following dissection, each knee was examined to determine the maximum extension angle, as described in previous methods\(^{34),37-39,43)}\). Angle 0° corresponds to the fullest possible extension. To reduce bias in the operations and measurements, the same veterinarian examined the extension levels for all rats.

**Measurement of focal bone mineral density (BMD)**

The mean focal BMD of the OA or sham-operated total knee joints, and femoral and tibial articular surfaces were detected by live dual-energy X-ray absorptiometry (DEXA; InAly zer, Medikors, Seungnam, Korea; g/cm\(^2\)).

**Measurement of CS**

Focal CS was detected on the femoral and tibial articular surfaces of the rats by Newton (SV-H1000, Japan Instrumentation System Co., Tokyo, Japan).

**Preparation of femoral and tibial AC with SM tissue homogenates**

Tissue homogenates were obtained from the femoral and tibial AC with SM using an ultrasonic cell disruptor (Model KS-750, Madell Technology Corp., Ontario, CA, USA). Tissue homogenates were centrifuged at 21,000 x g, and separated supernatants were used to detect PGE\(_2\) levels and 5-LPO, MMP-2 and MMP-9 activity.

**Determination of PGE\(_2\) levels**

The PGE\(_2\) levels were determined using a PGE\(_2\) assay kit (R&D Systems, Minneapolis, MN, USA) with the supernatants obtained from the femoral and tibial AC with SM. The optical densities were read at 540 nm with a microplate reader (Sunrise; Tecan, Männedorf, Switzerland; pg/mL), according to the manufacturer’s instructions.

**5-LPO activity assay**

5-LPO levels were determined using a Lipoxygenase Inhibitor Screening Assay kit was acquired from Cayman Chemical Company (Ann Arbor, MI, USA) with the supernatants obtained from the femoral and tibial AC with SM. The optical densities were read at 490 nm with a microplate reader (μM/min/mL), according to the manufacturer’s instructions.

**MMP inhibitory assay**

MMP-2 and MMP-9 activity were separately measured in the supernatants of femoral and tibial AC with SM tissue homogenates using a commercial MMP ELISA kit (Mybiosource, San Diego, CA, USA). Optical density was read as 560 nm (ng/mL) using a microplate reader, according to the manufacturer’s protocol.

**Reverse transcription–quantitative polymerase chain reaction (RT–qPCR) analysis of ECM-related chondrogenic gene mRNA expression**

Collagen type II, SOX9, and aggrecan mRNA expression levels in prepared femoral and tibial AC and in the SM homogenates were detected separately by RT–qPCR according to previously established methods\(^{44,45)}\). Briefly, RNA extraction was performed with TRIzol reagent, as per the method described in
previous studies\textsuperscript{7,13}}. The concentration of the RNA samples were analyzed using the CFX96\textsuperscript{TM} Real-Time System (Bio-Rad, Hercules, CA, USA). To obtain RNA with high integrity, recombinant DNase I (DNA-free; Ambion, Austin, TX, USA) was used for the removal of DNA contamination. The reverse transcription of RNA was conducted with the High-Capacity cDNA Reverse Transcription Kit (Applied Biosystems, Foster City, CA, USA) according to the manufacturer's protocols. The amplification of cDNA by PCR was conducted as follows: 58°C for 30 min, 94°C for 2 min, 35 cycles of 94°C for 15 sec, 60°C for 30 sec, 68°C for 1 min, and 72°C for 5 min. Analyses were performed using the ABI Step One Plus Sequence Detection System (Applied Biosystems, Foster City, CA, USA). Transcript levels were expressed as relative to the vehicle control. The mRNA level of \(\beta\)-actin was used as a loading control. Primer sequences were as follows: Collagen type II, 5'-GAGTGGAGAGGGACACTCTG-3' and 5'-CTCCATGTGGCAAGACTTCTCA-3'; SOX-9, 5'-AGAGCGTGGCTCGGAACACTGT-3' and 5'-TCCTGGGAGCAACTGGTAAA-3'; Aggrecan, 5'-GATGTCCCCTGCAATTACCA-3' and 5'-TCTGTGCAAGTGATTCGAGG-3'; \(\beta\)-actin, 5'-ATCGTGGGCCGCCCTAGGCA-3' and 5'-TGGCCTTAGGGTTCAGAGGGG-3'. The relative expression of collagen type II, SOX-9 and aggrecan was calculated using the 2\(^{-}\Delta\Delta\text{Cq}\) method\textsuperscript{46}).

5-bromo-2′-deoxyuridine uptake (BrdU) proliferation assay

To examine the effects of the test substances on the proliferation of cells, a BrdU assay was performed within the rat knee joints. The rats were intraperitoneally injected with BrdU (Sigma-Aldrich, St. Louise, MO, USA) at 72 h prior to sacrifice\textsuperscript{39,47}. BrdU uptake was detected by immunohistochemistry using an anti-BrdU antibody, as described previously\textsuperscript{34,37,38}, for the femoral and tibial AC and SM.

Histology

Samples were taken from the knee joints, including the joint capsules, and immersed in 10% neutral-buffered formalin for fixation. Next, the samples were decalcified using a decalcifying solution for 5 days. The sections from each knee joint were longitudinally trimmed, paraffin-embedded, serially sectioned (3-4 \(\mu\)m). In order to reduce interpretation bias, blinded histological assessments were conducted using a light microscope.

Immunohistochemistry

Corresponding purified primary antibodies were used to determine the immunoreactivity levels for the apoptotic marker PARP (Cell Signaling Technology Inc, Danvers, MA, USA, 9545) and the proinflammatory cytokines TNF-\(\alpha\) (Santa Cruz Biotechnology, Santa Cruz, CA, USA, sc-52746) and COX-2 (Cayman Chemical., Ann Arbor, MI, USA, 160126), using an avidin-biotin-peroxidase complex (ABC) and a peroxidase substrate kit (Vector Labs, Burlingame, CA, USA) for the femoral and tibial AC and SM tissues. Briefly, samples were incubated with methanol with 0.3% H\(_2\)O\(_2\) for 30 min to block endogenous peroxidase activity. The samples were then incubated with normal horse serum solution for 1 h to block non-specific immunoglobulin binding. The sections were incubated with the primary antibody at 4°C in a humidified chamber, then the biotinylated universal secondary antibody and ABC solutions were added at 18-25°C in the humidified chamber. Finally a peroxidase substrate kit was added for 3 min at 18-25°C, and the sections were washed three times in 0.01 M PBS for 10 min each.

Histomorphometry

The Mankin score was used to evaluate the femoral and tibial AC damages using the Safranin-O stain, as

http://dx.doi.org/10.13048/jkm.18037 91
previously recommended by a number of researchers. A high score represents a high level of OA (Semiquantitative scores; Max = 12). All histological analyses were performed by the same pathologist, who was blinded to the group distributions. In addition, the thicknesses of the tibial and femoral AC (μm/cartilage), the epithelial lining thickness of the SM (μm/knee joint) and the number of inflammatory cells infiltrating the SM (cells/mm²) were measured in longitudinally prepared and trimmed samples using automated image analyzer software (iSolution FL ver 9.1, IMT i-solution Inc., Vancouver, Quebec, Canada), according to our previously established methods. Samples were considered positive if >20% of the cells were immunoreactive to the BrdU, PARP, TNF-α or COX-2 antibodies as determined using an automated digital image analyzer (cells/mm²).

Statistical analyses

Data is shown as the mean ± SD of 10 rats. Differences between groups were tested using multiple comparison tests. The Levene test was performed for homogeneity of variance. Where there were no significant deviations from homogeneity of variance, the data were analyzed by a one-way analysis of variance followed by a least-significant difference (LSD) multiple comparison test to determine which pairs were significantly different. In cases of significant deviations from homogeneity of variance, the non-parametric Kruskal-Wallis H test was conducted instead; where significant differences were determined in the Kruskal-Wallis H test, the Mann-Whitney U test (MW) with Bonferroni's correction was performed to determine the intergroup difference. SPSS software (SPSS Inc., Chicago, IL, USA) was used for all statistical data analyses. P<0.05 was regarded as statistically significant.

Results

Changes in body weight

Ten rats were chosen for each group with distributed body weights at 6 days after OA induction; there were no significant differences in initial body weight between the rat groups. None of the PCP:EC:AR 5:4:1 (g/g) mixed formula-administrated groups displayed significant changes in body weight compared with those of the PCP, EC and AR single formula-administrated group throughout the experiment (Fig 1).

Changes in knee thickness

Significant increases in knee thickness were observed in OA control rats compared with sham control rats. OA-induced knee thickness significantly decreased after treatment with 200, 100 or 50 mg/kg PCP:EC:AR 5:4:1 (g/g) mixed formula. In particular, 200 and 100 mg/kg PCP:EC:AR 5:4:1 (g/g) mixed formula-treated rats dose-dependently decreased knee thickness compared with PCP, EC or AR single formula-treated rats from 1 day after initial administration. The 50 mg/kg PCP:EC:AR 5:4:1 (g/g) mixed formula induced significant decreases in knee thickness after 7 days (Fig 2).
Anti-osteoarthritic effects of a combination of pomegranate concentrate powder, *Eucommiae cortex* and *Achyranthis radix* in rats

Significant increases in capsule-exposed knee thickness were detected in OA control rats compared with sham control rats. However, significant decreases in knee thickness after capsule exposure were observed in all test substance-treated rat groups, including the PCP single formula-treated OA rats compared to OA control rats. The 200, 100 and 50 mg/kg PCP:EC:AR 5:4:1 (g/g) formula groups also showed dose-dependent decreases in capsule-exposed knee thickness compared with each PCP, EC, and AR single treatment group (Fig 3).

Effects on maximum knee extension angle

Significant increases in maximum knee extension angle were observed in the OA control rats compared to sham control rats; however, these angles were significantly decreased in response to 200, 100, and 50 mg/kg PCP:EC:AR 5:4:1 (g/g) compared with those of OA control rats. In particular, the 200, 100, and...
50 mg/kg PCP:EC:AR 5:4:1 (g/g) combination treated rats also showed dose-dependent decreases in maximum knee extension angle compared with each single formula group (Fig 4).

Effects on DEXA images and BMD

Noticeable OA-related signs were identified in the X-ray images of OA control rats, including loss of the knee joint region, femoral and tibial AC erosion and osteophyte formation. In addition, significant corresponding decreases in the focal BMD of the total knee joint, as well as the femoral and tibial articular surface regions, were observed in OA control rats compared with the sham control rats. However, notable decreases in OA-like X-ray signs and corresponding increases in the total knee joint, and femoral and tibial articular surface BMDs were observed in all of the test substance-treated rats, including the AR single formula-treated OA rats compared to OA control rats. In particular, the 200, 100 and 50 mg/kg combination treatment groups showed dose-dependent inhibition of OA-like X-ray signs, and significant increases in total knee joint, and femoral and tibial articular surface focal BMDs compared with groups treated with PCP, EC or AR alone (Table 1 and Fig 5).

Table 1. Effects of PCP:EC:AR 5:4:1 (g/g) Mixed Formula on Focal BMD

| Groups                  | Total knee joint BMD | Femur articular surface BMD | Tibia articular surface BMD |

Anti-osteoarthritic effects of a combination of pomegranate concentrate powder, *Eucommiae cortex* and *Achyranthis radix* in rats

Effects on the CS of the femoral and tibial AC

Femoral and tibial AC focal CS significantly decreased in OA control rats compared with sham control rats. By contrast, the 200, 100 and 50 mg/kg combination treatment groups showed an increased femoral and tibial AC focal CS compared with the OA control group. In particular, the 200, 100 and 50 mg/kg combination treatment groups showed dose-dependent and significant increases in focal CS for both femoral and tibial AC compared with the PCP, EC and AR single formula treatment groups (Fig 6).

Changes in PGE2 levels of the femoral and tibial AC with SM

PGE2 levels in the femoral and tibial AC with SM significantly increased in the OA control group compared with the sham control group. However, significant decreases in the femoral and tibial AC with SM PGE2 levels were observed in all of test substance-treated groups compared with the OA control group. Particularly, the 200, 100 and 50 mg/kg combination-treated groups showed significant and

---

**Table 2. Effects on PGE2 Levels of the Femur and Tibia AC with SM**

| Groups | PGE2 levels |
|--------|-------------|
|        | Femur AC | Tibia AC | SM          |
| Controls |          |          |            |
| Sham    | 42.62±10.55 | 37.01±12.19 | 32.24±12.83 |
| OA      | 123.76±24.73 | 107.08±16.92 | 147.25±31.90 |
| Diclofenac | 67.17±10.92 | 61.33±11.04 | 82.29±14.01 |
| Single formula (200 mg/kg) |          |          |            |
| PCP     | 89.51±11.70 | 79.44±12.33 | 101.94±12.84 |
| EC      | 93.98±10.51 | 87.54±9.02 | 110.92±11.50 |
| AR      | 93.59±15.54 | 84.60±11.38 | 109.41±17.30 |
| Mixed formula - PCP:EC:AR 5:4:1 (g/g) |          |          |            |
| 200 mg/kg | 56.15±13.54 | 48.79±8.35 | 69.45±16.84 |
| 100 mg/kg | 61.69±15.50 | 56.33±16.82 | 74.60±12.54 |
| 50 mg/kg | 67.92±12.07 | 62.96±11.29 | 83.93±10.99 |

Data are shown as mean ± SD of 10 rats, g/cm². OA, Osteoarthritis; AC, Articular cartilage; SM, Synovial membrane; PGE2, Prostaglandin E2; PCP, Pomegranate Concentration Powder; EC, Aqueous extracts of *Eucommiae Cortex*; AR, Aqueous extracts of *Achyranthis Radix*. *p<0.01 and *p<0.05, compared to the sham control; †p<0.01, compared to the OA control; and ‡p<0.01, compared to the PCP only; §p<0.01, compared to the AR only.

---
dose-dependent decreases in PGE2 levels in the femoral and tibial AC with SM compared with the PCP, EC and AR single treatment groups (Table 2).

5-LPO activity of the femoral and tibial AC with SM

The 5-LPO activity of the femoral and tibial AC with SM significantly increased in the OA control group compared with the sham control group. However, significant decreases in the 5-LPO activity of the femoral and tibial AC with SM were observed in all test substance-treated groups compared with the OA control group. In particular, the 200, 100 and 50 mg/kg combination-treated groups showed dose-dependent decreases in 5-LPO activity compared with the PCP, EC and AR single treatment groups (Table 3).

Changes in the MMP-2 and MMP-9 activity of the femoral and tibial AC with SM

The MMP-2 and MMP-9 activity increased significantly in the OA control group compared with the sham control group. However, significant decreases in the femoral and tibial AC with SM MMP-2 and MMP-9 activity were observed in all of the test substance-treated groups compared with the OA control group. In particular, the 200, 100 and 50 mg/kg combined treatment groups showed dose-dependent decreases in MMP-2 and MMP-9 activity compared with the PCP, EC and AR single treatment groups (Table 4 and 5).

Effects on the mRNA expression of collagen type II, SOX9 and aggrecan

There was a significant reduction in the transcript levels of collagen type II, SOX9 and aggrecan in the femoral and tibial AC, which were significantly higher in the OA control group compared with the sham control group (Table 6-8). However, dose-dependent increases in femoral and tibial AC, and decreases in the SM collagen type II mRNA expression were observed in the 200, 100 and 50 mg/kg

### Table 3. Effects on 5-LPO Activities of Femur and Tibia AC with SM

| Groups | Items | Femur AC | 5-LPO activity | Tibia AC | SM |

| 50 mg/kg  | 178.30±28.55  | 183.10±27.57  | 265.20±82.74  |

Values are expressed mean ± SD of 10 rats, cells/mm². AR = Aqueous extracts of *Achyranthis Radix*; OA = Osteoarthritis; EC = Aqueous extracts of *Eucommiae Cortex*; PCP = Pomegranate Concentration Powder; AC = Articular cartilage; SM = Synovial membrane; BrdU = 5-Bromo-2'-Deoxyuridine; *p*<0.01 and *b* *p*<0.05 as compared with sham control; *c* *p*<0.01 as compared with OA control; and *d* *p*<0.01 as compared with PCP single formula; *e* *p*<0.01 as compared with EC single formula; *f* *p*<0.01 as compared with AR single formula.
of the diclofenac-treated group, in which a similar number of BrdU-immunoreactive cells was detected in the femoral and tibial AC compared with the OA control group. In particular, the 200, 100 and 50 mg/kg combination treatment groups showed significant dose-dependent increases in the number of BrdU-immunolabeled cells in the femoral and tibial AC, but decreases in the SM compared with the PCP, EC and AR single treatment groups (Fig 7, Table 9).

Changes in the femoral and tibial AC Mankin scores

In the OA control rats, the surface of the cartilage became rough and the number of chondrocytes decreased. Safranin-O stain intensities were reduced on the femoral and tibial AC, and femoral and tibial AC Mankin scores in the OA control group were significantly higher than those of the sham control group. However, significant decreases in the femoral and tibial AC Mankin scores were observed in all of the test substance-treated groups compared to the OA control group. In particular, the 200, 100 and 50 mg/kg combination treatment groups showed dose-dependent decreases in the femoral and tibial AC Mankin scores compared with the PCP, EC and AR single treatment groups (Table 10 and 11).
Anti-osteoarthritic effects of a combination of pomegranate concentrate powder, Eucommiae cortex and Achyranthis radix in rats

Data are shown as mean ± SD of 10 rats, g/cm². Possible scores ranged from 0 to 12. OA, Osteoarthritis; AC, Articular cartilage; SM, Synovial membrane; PCP, Pomegranate Concentration Powder; AR, Aqueous extracts of Achyranthis Radix; EC, Aqueous extracts of Eucommiae Cortex; AC. a p<0.01 and b p<0.05, compared to the sham control; c p<0.01 and d p<0.05, compared to the OA control; e p<0.01, compared to the PCP only; f p<0.01, compared to the EC only; g p<0.01 and h p<0.05, compared to the AR only.

Changes in the general histopathology of the femoral and tibial AC with SM

Remarkable reductions in the femoral and tibial AC thickness were observed in the OA control group compared with the sham control group, and significant increases in the SM epithelial lining thickness were detected in the OA control group. In contrast, remarkable increases in the thicknesses of the femoral and tibial AC, and significant decreases in the SM epithelial lining thickness were detected in all test substance-treated groups compared with the OA control group. Of note, the 200, 100, and 50 mg/kg combination treatment
groups showed dose-dependent increases in the femoral and tibial AC thicknesses compared with the PCP, EC and AR single treatment groups. Significant increases in the number of inflammatory cells that infiltrated the SM were detected in the OA control group compared with the sham control group. Significant decreases in the number of inflammatory cells that infiltrated the SM were observed in the 200, 100, and 50 mg/kg

combination treatment groups compared with the OA control group (Fig 8, Table 12).

Effects on the PARP-immunoreactive cells in the femoral and tibial AC with SM

The number of PARP-immunoreactive cells in the femoral and tibial AC with SM was significantly increased in the OA control group, while all test substance-treated groups showed significant decreases in PARP immunoreactivity compared with the control groups. In particular, the 200, 100, and 50 mg/kg combination treatment groups showed significant, dose-dependent decreases in the number of PARP-immunolabeled cells in the femoral and tibial AC, and SM compared with the PCP, EC and AR single treatment groups (Fig 9, Table 13).
Significant increases in the number of femoral and tibial AC SM COX-2 and TNF-α-immunoreactive cells were detected in the OA control group. Conversely, COX-2- and TNF-α-immunoreactive cells of the femoral and tibial AC, and SM were significantly lower in all test substance-treated groups when compared with the OA control group. Of note, the 200, 100 and 50

Effects on COX-2 and TNF-α immunoreactive cells in the femoral and tibial AC with SM

Significant increases in the number of femoral and tibial AC SM COX-2 and TNF-α-immunoreactive cells were detected in the OA control group. Conversely, COX-2- and TNF-α-immunoreactive cells of the femoral and tibial AC, and SM were significantly lower in all test substance-treated groups when compared with the OA control group. Of note, the 200, 100 and 50
mg/kg combination treatment groups showed significant decreases in the number of COX-2- and TNF-α-immunolabeled cells in the femoral and tibial AC, and SM, compared with the PCP, EC and AR single treatment groups (Fig 10 and 11, Table 14 and 15)).
**Discussion**

Several previous studies have reported that PCP, EC and AR have individual disease-modifying effects against OA\(^{15-17,26,27,29,30}\). Furthermore, our previous *in vitro* studies showed that pretreatment with PCP, EC and AR (1 mg/mL) inhibited inflammatory damage to chondrocytes by lipopolysaccharide and ECM degradation induced by recombinant human IL-1\(\alpha\)\(^{35}\). An *in vivo* study\(^{36}\) showed that a PCP:EC:AR ratio of 5:4:1 had the highest inhibitory activity against surgically induced OA among nine mixed formulations of PCP with EC and AR. Nevertheless, our previous study focused on determining the appropriate proportions for further examining the effects of the PCP:EC:AR 5:4:1 (g/g) mixed formula. Dose-response information is necessary for the safe and effective use of a novel formula. Thus, to obtain additional information, this study examined the dose-dependent anti-OA potential of the 5:4:1 (g/g) PCP:EC:AR formulation on rats with surgically induced OA.

OA is a type of chronic degenerative inflammatory disease that results from the destruction of joint cartilage. During the progression of OA, cartilage damage can induce the release of leukotrienes, potent inflammatory mediators, by increasing COX-2 and 5-LPO activity, coordinated by IL-1 and TNF-\(\alpha\). IL-1 and TNF-\(\alpha\) increase the production of NO and PGE\(_2\), disrupting the ability of chondrocytes to maintain cartilage homeostasis\(^{48}\). These acute inflammatory factors contribute to the increase in joint thickness and abnormal bone growth of painful osteophytes, and edematous changes to the surrounding tissue\(^{13,49-51}\). Conversely, suppressing these inflammatory factors ameliorates OA symptoms. As a result, OA control rats showed an increase in knee thickness. In addition, decreases in the femoral and tibial AC thickness were detected. The number of COX-2- and TNF-\(\alpha\)-immunolabeled cells increased, along with an increase in PGE\(_2\) and LPO activity. However, these alterations were inhibited by the PCP:EC:AR 5:4:1 (g/g) combination in a dose-dependent manner. The 50 mg/kg PCP:EC:AR 5:4:1 (g/g) mixed formula showed favorable anti-inflammatory activity comparable to 2 mg/kg diclofenac, and was more potent than 200 mg/kg PCP, EC or AR used alone. These results support that the PCP:EC:AR 5:4:1 (g/g) formula effectively inhibited OA by inhibiting inflammatory activity in rats with surgically induced OA.

Physical injuries can cause the loss of a joint region, cartilage erosion and osteophyte formation. These changes can be observed by gross observation and X-ray images\(^{37,52}\), and are considered a reasonable index for measuring the efficacy of anti-OA drugs\(^{53,54}\). BMD is used as a predictor of bone disease susceptibility\(^{55,56}\) as well as for information regarding bone quality in osteoporosis treatment trials\(^{57}\). Additionally, the measurement of focal BMDs and bone strength can be used to estimate the extent of OA progression\(^{58-61}\). As a result, we observed loss of the knee joint region, femoral and tibial AC erosion, and osteophyte formation in OA control rats through DEXA image analysis. In addition, corresponding significant decreases in the focal BMD of the total knee joint, and the femoral and tibial AC surface regions were observed concomitantly with the decrease in femoral and tibial AC focal CS in the OA control group compared with the sham control group. Surgically induced OA-related focal loss of AC, osteophyte formation and decreased BMD and CS in OA-model rats were dose-dependently inhibited by treatment with the 200, 100 and 50 mg/kg PCP:EC:AR 5:4:1 (g/g) combination. We speculate that the surface cartilage CS may be involved in the formation of a component of the ECM and conditioning of chondrocytes. Healthy ECM and chondrocytes improve compressive strength.
MMPs are pivotal proteolytic enzymes involved in deconstructing chondrocytes and bony tissue. Under normal conditions, MMPs are suppressed by the tissue inhibitor of metalloproteinase system. MMPs act as proteases that degrade the ECM, predominately PG, and are responsible for the destruction of cartilage components. Thus, inhibiting MMPs is a reasonable strategy to treat OA. The induction of OA by surgery increased the MMP-2 and -9 activity in the femoral and tibial AC, and SM, while the combination treatment dose-dependently suppressed these alterations. These results indicate that PCP:EC:AR 5:4:1 (g/g) will potentially be useful to treat OA.

An important indicator of OA is fibrosis, resulting in joint stiffness and pain. Fibrosis is defined as the excessive accumulation of connective tissue, potentially leading to organ malfunction. The maximum extension angle of a joint is used as a measure of its stiffness. 0° indicates the maximum extension. The lower the value, the better the knee function. The maximum extension angles in knees of OA rats were dose-dependently increased by 200, 100 or 50 mg/kg PCP:EC:AR 5:4:1 (g/g) treatment. In addition, OA-induced hypertrophy and hyperplasia of the SM were also dose-dependently inhibited by 200, 100 and 50 mg/kg PCP:EC:AR 5:4:1 (g/g). Our results indicate that PCP:EC:AR 5:4:1 (g/g) synergistically ameliorated OA-related joint stiffness.

The Mankin scoring system is widely accepted as a histopathological method to examine AC damage, including cartilage surface damage, decreased chondrocyte numbers, clone formation and Safranin-O stain intensity. In this system, the higher the score, the higher the level of OA. Decreases in AC thickness are consistently detected in OA model animals. We observed that the Mankin scores dose-dependently decreased in response to treatment with the PCP:EC:AR 5:4:1 (g/g) mixed formula for both the femoral and tibial AC compared with the OA control group. The extent of OA-decreased femoral and tibial AC thickness was also ameliorated in PCP:EC:AR 5:4:1 (g/g) combination-treated rats compared with the OA control rats. As the PCP:EC:AR 5:4:1 (g/g) combination dose-dependently decreased OA-related joint stiffness, it suggests that the combination could be suitable to relieve OA symptoms.

Apoptosis is a regulated form of cell death involved in development, homeostasis and aging. Chondrocytes are the only cell type in the AC, so the dysregulation of chondrocyte death and survival can lead to the disintegration of the AC. In the current study, PARP was selected as an apoptotic marker. The PARP immunoreactivity increased in the femoral and tibial AC, and SM, after OA surgery. Treatment with the PCP:EC:AR 5:4:1 (g/g) combination dose-dependently decreased OA-induced PARP immunoreactivity. The inhibition of apoptosis by PCP:EC:AR 5:4:1 (g/g) is evidence of its protective effect against OA.

BrdU immunohistochemistry can be used to detect chondrocyte proliferation in cartilage. When the chondrocytes have proliferative capacity, the cell will uptake BrdU. BrdU-immunoreactivity was significantly reduced in the femoral and tibial AC of the OA control group, indicating the inhibition of OA-related chondrocyte proliferation. The number of BrdU-positive chondrocytes in the sham control group was significantly lower than in the OA control group, indicating OA-associated fibrosis and hyperplasia at the SM. However, the number of BrdU-immunostained cells notably increased in response to the 200, 100 and 50 mg/kg PCP:EC:AR 5:4:1 (g/g) combination treatments in both femoral and tibial AC, but decreased in the SM. The enhancement of chondrocyte proliferation by PCP:EC:AR 5:4:1 (g/g) treatment suggests that PCP:EC:AR 5:4:1 (g/g) is a promising.
agent for the treatment of OA.

AC must tolerate repetitive physical stress on the human body. It is connective tissue composed of chondrocytes within an ECM of collagen, PG, aggrecan and SOX9\(^6\)\(^7\). Changes in the ECM are a major feature in the pathogenesis of OA. AC is damaged by physical force, loses PG content, and undergoes swelling and hypertrophy. Chondrocytes release degradative enzymes when they detect these changes in the ECM. ECM degradation is associated with inflammation, chondrocyte death and damage leading to the failure of the maintenance and function of AC\(^7\)\(^6\). The transcription factor SOX9 plays an important role in chondrogenic differentiation\(^7\)\(^7\). Collagen and aggrecan in the ECM are key components of healthy cartilage\(^4\)\(^5\). Therefore, preventing ECM degradation is a relevant approach for the treatment of OA\(^4\)\(^4\),\(^4\)\(^5\),\(^7\)\(^8\). Treatments with the PCP:EC:AR 5:4:1 (g/g) combination dose-dependently downregulated the OA-associated reduction in the transcript levels of collagen type II, and increased the transcript levels of chondrogenic genes in the SM. All doses of the combined treatment significantly increased the ECM formation-related factors in the rats with surgically induced OA when compared with each individual treatment. These results suggest that the PCP:EC:AR 5:4:1 (g/g) formula facilitated ECM formation in rats with surgically induced OA.

**Conclusion**

The results of this study suggest that the PCP:EC:AR 5:4:1 (g/g) combination synergistically increased the anti-OA effects of each ingredient through anti-inflammatory and chondrogenic activity in rats with surgically induced OA. 200, 100 and 50 mg/kg PCP:EC:AR 5:4:1 (g/g) treatments showed dose-dependent inhibitory activity against OA-related signs compared with 200 mg/kg PCP, EC or AR. The 50 mg/kg PCP:EC:AR 5:4:1 (g/g) treatment showed similar protective effects on the AC to 2 mg/kg diclofenac. Therefore, it is expected that the PCP:EC:AR 5:4:1 (g/g) combination formula is a promising new potent AC-protective agent for relieving various signs of OA.
