ON THE CONVERGENCE OF OPTIMISTIC POLICY ITERATION
FOR STOCHASTIC SHORTEST PATH PROBLEM

YUANLONG CHEN

Abstract. In this paper, we prove some convergence results of a special case of
optimistic policy iteration algorithm for stochastic shortest path problem mentioned
in [5]. We consider both Monte Carlo and TD($\lambda$) methods for the policy evaluation
step under the condition that termination state will eventually be reached almost
surely.

1. Introduction

In this paper we consider a Markov decision process (MDP) with a finite state set
$S = \{1, 2, \ldots, n\}$. In addition, we use 0 to denote the cost-free termination state. For
each state $i$, we assume there are only finite actions, denoted as $U(i)$. Furthermore,
for each state $i \in S$ and each action $u \in U(i)$, we associate a transition probability
$p_{i,j}(u)$ and an immediate cost function $g(i, u)$. A policy $\mu$ is defined as a mapping
from $S$ to $U$(note there are only finitely many policies since states and actions are
both finite). Let’s denote by $X^\mu_t$ at the state time step $t$ under the policy $\mu$. \{${X^\mu_t}$\}
then forms a Markov chain with transition probability

$$P(X^\mu_{t+1} = j | X^\mu_t = i) = p_{i,j}(\mu(i)).$$

The total expected cost(cost-to-go) of the process starting from state $i$ under policy
$\mu$ is

$$J^\mu(i) = E \left[ \sum_{t=0}^{\infty} \alpha^t g(X^\mu_t, \mu(X^\mu_t)) | X^\mu_0 = i \right],$$

where $0 < \alpha \leq 1$ is the discounted factor. A policy $\mu$ is said to be proper if, under this
policy, there is positive probability that the termination state will be reached after
at most $n$ steps, regardless of the initial state, that is, if

$$\rho_\mu = \max_{i \in S} P(X^\mu_n \neq 0 | X^\mu_0 = i) < 1.$$ (1)

Proper policy basically implies that the termination state will eventually reached
almost surely. To see this, note that

$$P(X^\mu_t \neq 0 | X^\mu_0 = i) \leq \rho_\mu^{\lfloor t/n \rfloor}, \quad \forall i \in S.$$ (2)

The conclusion then follows from Borel-Cantelli lemma. Moreover, $J_\mu$ is finite when
$\mu$ is proper, since

$$|J_\mu(i)| \leq \lim_{T \to \infty} \sum_{t=0}^{T-1} \alpha^t \max_j |g(j, \mu(j))| < \infty, \quad \forall i \in S.$$ (3)

In this paper, we assume every policy is proper.

Assumption 1.1. Every policy in our problem is proper.

Key words and phrases. Optimistic Policy Iteration, Convergence, Stochastic Shortest Path.
In the following context, we only consider the stochastic shortest path problem in which scenario $\alpha = 1$. We denote the optimal cost-to-go function starting from $i$ as $J^*(i)$, that is the minimal value of cost-to-go functions among all of the policies,

$$J^*(i) = \min_{\mu} J^\mu(i).$$

Note the minimal value can be achieved since there are only finite policies. We then define the optimal cost-to-go vector as $J^* = (J^*(1), \ldots, J^*(n))$. A policy $\mu$ is said to be optimal if $J^\mu(i) = J^*(i)$ for every $i \in S$.

We next introduce two dynamic programming operators. For any $n$ dimensional vector $J = (J(1), \ldots, J(n))$, define operator $T : \mathbb{R}^n \to \mathbb{R}^n$ as

$$(TJ)(i) = \min_u \left\{ g(i, u) + \sum_{j=1}^{n} p_{i,j}(u)J(j) \right\}, \quad \forall i \in S.$$ 

Similarly, define $T_\mu : \mathbb{R}^n \to \mathbb{R}^n$ as

$$(T_\mu J)(i) = g(i, \mu(i)) + \sum_{j=1}^{n} p_{i,j}(\mu(i))J(j), \quad \forall i \in S.$$ 

In vector notation, they are equivalent to

$$(TJ)(i) = \min_\mu (T_\mu J)(i), \quad \forall i \in S,$$

and

$$T_\mu J = g_\mu + P_\mu J.$$ 

These two operators associated with stochastic shortest path problem have some well-known properties, for which we summarize as the following proposition (for the proof one can refer to [1], [2], [3]).

**Proposition 1.2.** Under Assumption 1.1, the following properties hold for the stochastic shortest path problem:

(a) The optimal cost-to-go vector $J^*$ has finite components and it satisfies

$$J^* = TJ^*.$$ 

Furthermore, $J^*$ is the only solution for the equation above.

(b) For every vector $J$, we have

$$\lim_{k \to \infty} T^k J = J^*.$$ 

(c) A policy $\mu$ is optimal if and only if

$$T_\mu J^* = TJ^*.$$ 

(d) For every proper policy $\mu$, the associated cost-to-go vector $J^\mu$ satisfies

$$\lim_{k \to \infty} T_\mu^k J = J^\mu,$$

for every vector $J$. Furthermore,

$$J^\mu = T_\mu J^\mu,$$

and $J^\mu$ is the only solution for the equation above.
Throughout this paper, for an \( n \) dimensional vector \( J \), we use \( \| \cdot \| \) to denote the maximum norm, defined by
\[
\|J\| = \max_i |J(i)|.
\]
For a given \( n \) dimensional vector \( \xi = (\xi(1), \ldots, \xi(n)) \) with all components positive, we use \( \| \cdot \|_{\xi} \) to denote the weighted maximum norm with respect to \( \xi \), defined by
\[
\|J\|_{\xi} = \max_i \frac{|J(i)|}{\xi(i)}.
\]
For two vectors \( J \) and \( \bar{J} \), we say \( J \leq \bar{J} \), if \( J(i) \leq \bar{J}(i) \) for all \( i \in S \). \( J < \bar{J} \) has the meaning in the same manner.

We also notice the following useful monotonicity properties of \( T \) and \( T_\mu \) (see Lemma 2.1 in [4]):

**Proposition 1.3.** For all \( n \) dimensional vector \( J \) and \( \bar{J} \), such that
\[
J \leq \bar{J},
\]
for any policy \( \mu \) and any positive integer \( k \), we have
\[
T^k J \leq T^k \bar{J}, \quad T_\mu^k J \leq T_\mu^k \bar{J}.
\]

Let’s denote by \( e \) the \( n \) dimensional vector with all components equal to 1, the following result is a direct consequence of an induction argument and Proposition 1.3:

**Lemma 1.4.** For every positive scalar \( c \) and vector \( J \), we have
\[
T^k (J + ce) \leq T^k J + ce, \quad \forall k > 0,
\]
\[
T_\mu^k (J + ce) \leq T_\mu^k J + ce, \quad \forall k > 0.
\]

For \( T_\mu \), we also have the following lemma

**Lemma 1.5.** Given a scalar sequence \( \{\lambda_l\}_{l=0}^{\infty} \) such that \( 0 < \lambda_l < 1 \) and \( \sum_l \lambda_l = 1 \), for any bounded vector sequence \( \{J_l\}_{l=0}^{\infty} \), we have
\[
T_\mu \left( \sum_{l=0}^{\infty} \lambda_l J_l \right) = \sum_{l=0}^{\infty} \lambda_l T_\mu J_l.
\]

**Proof.** First note that for any positive integer \( L \), we have
\[
T_\mu \left( \sum_{l=0}^{\infty} \lambda_l J_l \right) = T_\mu \left( \sum_{0 \leq l \leq L} \lambda_l J_l + \sum_{l > L} \lambda_l J_l \right)
\]
\[
= \sum_{0 \leq l \leq L} \lambda_l g_\mu + \sum_{0 \leq l \leq L} \lambda_l P_\mu J_l + \sum_{l > L} \lambda_l g_\mu + P_\mu \left( \sum_{l > L} \lambda_l J_l \right)
\]
\[
= \sum_{0 \leq l \leq L} \lambda_l T_\mu J_l + \sum_{l > L} \lambda_l g_\mu + P_\mu \left( \sum_{l > L} \lambda_l J_l \right).
\]
It’s easy to see that
\[
\lim_{L \to \infty} \sum_{l > L} \lambda_l = 0.
\]
Note $J_l$ is bounded, thus we have
\[
\lim_{L \to \infty} \sum_{l > L} \lambda_l J_l = 0.
\]
Since $g_u$ and $P_\mu$ are both bounded, the conclusion then follows easily.

We now give a brief description of policy iteration algorithm. In the ordinary policy iteration procedure, we start with some initial policy $\mu$, and then we do the policy evaluation, i.e. evaluate the optimal cost-to-go vector $J_\mu$ corresponding to $\mu$. In this step, for example, one can use learning algorithms such as Monte Carlo or $TD(\lambda)$. Once we have the cost-to-go vector $J_\mu$, we perform policy improvement step, which updates $\mu$ as
\[
\mu(i) \leftarrow \arg \min_{u \in U(i)} \left\{ g(i, u) + \sum_{j=1}^{n} p_{i,j}(u) J_\mu(j) \right\}, \quad \forall i \in S.
\]

Such process is repeated until the algorithm converges.

One disadvantage of the algorithm described above is that, in practice, the accurate evaluation of the cost-to-go vector $J_\mu$ could be expensive which makes the algorithm inefficient. Optimistic policy iteration is a variation of the ordinary policy iteration to address this issue in which the policy improvement is based on an incomplete evaluation of $J_\mu$ instead of an accurate $J_\mu$. For example, if we apply Monte Carlo method in policy evaluation step, in the ordinary policy iteration algorithm, theoretically, a large number of trajectories need to be simulated to guarantee an accurate estimation. In contrast, for optimistic policy iteration, we perform policy improvement immediately after one single trajectory sample. In [5], the convergence results have been established for discounted problems ($0 < \alpha < 1$) based on both Monte Carlo and $TD(\lambda)$ methods. In the following sections, we will show that the similar convergence results can be extended to (undiscounted) stochastic shortest path problem ($\alpha = 1$).

2. Monte Carlo based optimistic policy iteration

We first provide a precise description of the optimistic policy iteration algorithm. We start with some random vector $J_0$ and policy $\mu_0$. The iteration proceeds as follows: at each time step $t$, for each state $i$, we simulate a single trajectory which starts with $i$ under the policy $\mu_t$ (note that the termination is guaranteed since the policy is proper). The observed cumulative cost is an unbiased estimate of $J_\mu^t(i)$, for which we denote by $J_\mu^t(i) + \omega_t(i)$, where $\omega_t(i)$ is a zero-mean noise. We then update vector $J_t$ according to the following update rule
\[
J_{t+1}(i) = (1 - \gamma_t) J_t(i) + \gamma_t (J_\mu^t(i) + \omega_t(i)),
\]
where $\gamma_t$ is a deterministic scalar stepsize parameter. Furthermore, we impose the well-known step-size conditions for $\gamma_t$
\[
\sum_{t=0}^{\infty} \gamma_t = \infty, \quad \sum_{t=0}^{\infty} \gamma_t^2 < \infty.
\]

Let $F_t$ be the history of the algorithm up to and including the point where $J_t$ has been produced, but before simulating the trajectories for the next update, based on the argument in [5], we know that
\[
E[\omega_t(i)|F_t] = 0,
\]
and
\[ E \left[ |\omega_t(i)|^2 |\mathcal{F}_t \right] \leq C, \]
for some positive constant \( C \).

We summarize our main result as the following theorem:

**Theorem 2.1.** The sequence \( J_t \) generated by the optimistic policy iteration algorithm according to (2.1) for the stochastic shortest path problem, converges to the optimal cost-to-go vector \( J^* \), almost surely.

Before proving Theorem 2.1, let us establish several preliminary results.

**Lemma 2.2.** For any given \( \epsilon > 0 \) and \( M > 0 \), there exists a positive integer \( K = K(\epsilon, M) \) such that for all policy \( \mu \) and vector \( J \) such that \( \|J\| \leq M \), we have
\[ \|T^K_{\mu}J - J^\mu\| < \epsilon. \]

**Proof.** Since there are only finitely many possible policies, it suffices to prove the result for just one policy \( \mu \). For any given \( n \) dimensional vector \( J \), by part (d) of Proposition 1.2, we have
\[ \lim_{k \to \infty} T^k_{\mu}J = J^\mu. \]
It follows that, for any given \( \epsilon > 0 \), there exists a \( K(\epsilon) > 0 \), such that
\[ \|T^k_{\mu}J - J^\mu\| < \epsilon/2, \quad \forall k \geq K(\epsilon). \]
Note that we the following estimate
\[ \|T^k_{\mu}J - T^k_{\mu}\bar{J}\| \leq \|J - \bar{J}\|. \]
An easy inductive argument shows that
\[ \|T^k_{\mu}J - T^k_{\mu}\bar{J}\| \leq \|J - \bar{J}\|, \quad \forall k \geq 1. \]
Thus, for this \( \epsilon \), we have \( \|T^k_{\mu}J - T^k_{\mu}\bar{J}\| < \epsilon/2 \) for all \( k \geq 1 \) and \( \bar{J} \), as long as \( \|J - \bar{J}\| < \epsilon/4 \). Define \( B_\epsilon(J) = \{J||J - \bar{J}| < \epsilon/4\} \), then
\[ \|T^k_{\mu}\bar{J} - J^\mu\| < \epsilon, \quad \forall \bar{J} \in B_\epsilon(J), \forall k \geq K(\epsilon). \]

Set \( R = \{J||J| \leq M \} \), \( R \) is a compact set, and \( \{B_\epsilon(J)\}_{J \in R} \) form a open cover of \( R \). By Heine-Borel theorem, there exists a finite subcover, say \( B_\epsilon(J_1), \ldots, B_\epsilon(J_l) \). Set
\[ K = \max_{i \in \{1, \ldots, l\}} K(J_i) < \infty, \]
the conclusion then follows. \( \square \)

**Lemma 2.3.** The sequence \( J_t \) generated by optimistic policy iteration algorithm according to (2.1) is bounded almost surely.

**Proof.** Since there are only finitely many possible policies, \( J^\mu_t \) is bounded for any \( t \).

Note that the update rule is
\[ J_{t+1} = (1 - \gamma_t)J_t + \gamma_t J^\mu_t + \gamma_t \omega_t. \]
The boundedness of sequence \( J_t \) is then a direct consequence of Proposition 4.7 on p. 159 in [4]. \( \square \)

Define a scalar sequence \( c_t \) by setting
\[ (2.2) \quad c_t = \max_i \left( (TJ_t)(i) - J_t(i) \right), \]
we have
Lemma 2.4. For sequence \( c_t \), the following estimate holds
\[
\lim_{t \to \infty} \sup c_t \leq 0.
\]

Proof. The proof is essentially identical as in [5] with just a few minor modifications. Recall that in vector form
\[
T_{\mu_t} J = g_{\mu_t} + P_{\mu_t} J, \quad \forall J.
\]
By the same calculation in [5], we have
\[
T_{\mu_{t+1}} J_{t+1} - J_{t+1} \leq (1 - \gamma_t)(T_{J_t} - J_t) + \gamma_t v_t,
\]
where \( v_t = P_{\mu_t} \omega_t - \omega_t \). For this \( v_t \), we still have the following properties:
\[
E[v_t(i)|F_t] = 0, \quad \forall i \in S,
\]
and
\[
E[v_t(i)^2|F_t] \leq C, \quad \forall i \in S,
\]
for some constant \( C \). The rest of the proof is identical to the argument in [5]. \( \square \)

Lemma 2.5. For all \( \epsilon > 0 \), there exists a \( t(\epsilon) > 0 \) such that for all \( t \geq t(\epsilon) \), we have
\[
J^\mu_t \leq T J_t + \epsilon e.
\]

Proof. The definition of \( \mu_t \) tells us \( T_{\mu_t} J_t = T J_t \), it follows that
\[
T_{\mu_t} J_t = J_t + (T J_t - J_t) \leq J_t + c_t e.
\]
Apply \( T_{\mu_t} \) to both sides of inequality (2.4) by \( k - 1 \) times, an easy inductive argument and Lemma 1.4 show that
\[
T_k J_t \leq J_t + kc_t e.
\]
By Lemma 2.3, there exists a constant \( M \) such that \( |J_t| \leq M \) for all \( t \) almost surely. According to Lemma 2.2, for all \( \epsilon > 0 \), there exists \( K = K(\epsilon, M) \), such that for all \( J_t \), the following estimates are valid,
\[
\|T^K_{\mu_t} J_t - J^\mu_t\| < \epsilon/2.
\]
We now fix \( K \). By Lemma 2.4, for this fixed \( \epsilon \), there exists \( t(\epsilon) > 0 \), such that for all \( t \geq t(\epsilon) \)
\[
K c_t \leq \frac{\epsilon}{2} e,
\]
it then follows from (2.5) that
\[
T^K_{\mu_t} J_t \leq J_t + \frac{\epsilon}{2} e.
\]
Combine (2.6) and (2.7), we have
\[
J^\mu_t = J^\mu_t - T^K_{\mu_t} J_t + T^K_{\mu_t} J_t \leq \frac{\epsilon}{2} e + J_t + \frac{\epsilon}{2} e = J_t + \epsilon e.
\]
Apply \( T_{\mu_t} \) on both sides of the inequality above, using Lemma 1.4 and the fact that \( T_{\mu_t} J^\mu_t = J^\mu_t \), we see that for all \( t \geq t(\epsilon) \)
\[
J^\mu_t \leq T_{\mu_t} J_t + \epsilon e = T J_t + \epsilon e.
\]
\( \square \)
Proof of Theorem 2.1. Having established (2.3), the rest of the proof is essentially the same as the argument in Proposition 1 in [5]. First we note that for all corresponding greedy policy \( \mu \),

\[
J_{t+1} = (1 - \gamma_t) J_t + \gamma_t J^\mu_t + \gamma_t \omega_t,
\]

\[
\leq (1 - \gamma_t) J_t + \gamma_t T J_t + \gamma_t \epsilon \epsilon + \gamma_t \omega_t.
\]

For this fixed \( \epsilon \), we define a sequence \( Z_t \) that starts from time \( t(\epsilon) \) by setting \( Z_{t(\epsilon)} = J_{t(\epsilon)} \) and

\[
Z_{t+1} = (1 - \gamma_t) Z_t + \gamma_t T Z_t + \gamma_t \epsilon \epsilon + \gamma_t \omega_t, \quad \forall t \geq t(\epsilon).
\]

An easy inductive argument shows that \( J_t \leq Z_t \) for all \( t \geq t(\epsilon) \). Using the identical argument as in the proof of Proposition 1 in [5], we can derive

\[
\limsup_{t \to \infty} J_t \leq J^*,
\]

and

\[
\liminf_{t \to \infty} J_t \geq J^*.
\]

Thus, we have

\[
\lim_{t \to \infty} J_t = J^*.
\]

□

3. TD(\( \lambda \)) Based Optimistic Synchronous Policy Iteration

In this section, we extend the results in the previous section to TD(\( \lambda \)) based optimistic policy iteration algorithm. TD(\( \lambda \)) based algorithm is essentially the same as Monte Carlo based algorithm described in the previous section except that, in policy evaluation step, TD(\( \lambda \)) based algorithm uses temporal difference method instead of Monte Carlo method. Precisely, at iteration \( t \), we have a vector \( J_t \) and the corresponding greedy policy \( \mu_t \), for each state \( i \), we simulate a trajectory \( i_0, i_1, \ldots \) that starts with \( i \), then update \( J_t(i) \) to \( J_{t+1}(i) \) according to

\[
J_{t+1}(i) = J_t(i) + \gamma_t \sum_{k=0}^{\infty} \lambda^k d_k, \quad \lambda \in [0, 1),
\]

where \( d_k \) is called temporal difference defined as \( d_k = g(i_k, \mu_t(i_k)) + J_t(i_{k+1}) - J_t(i_k) \) and \( \gamma_t \) is a scalar stepsize parameter. This is equivalent to

\[
J_{t+1}(i) = (1 - \gamma_t) J_t(i) + \gamma_t (1 - \lambda) \sum_{k=0}^{\infty} \lambda^k (g(i_0) + g(i_1) + \cdots + g(i_k) + J_t(i_{k+1})).
\]

In vector notation, we have

\[
J_{t+1} = (1 - \gamma_t) J_t + \gamma_t (1 - \lambda) \sum_{k=0}^{\infty} \lambda^k T_{\mu_t}^{k+1} J_t + \gamma_t \omega_t,
\]

where \( \omega_t \) is a noise vector with zero mean reflecting the difference between the observed temporal differences and their expected values.

Before heading to our main result, let us first take a look at two extreme cases \( \lambda = 1 \) and \( \lambda = 0 \) to get some intuition of the TD(\( \lambda \)) based algorithm. If \( \lambda = 1 \), the update rule (3.1) becomes

\[
J_{t+1} = (1 - \gamma_t) J_t + \gamma_t \sum_{k=0}^{\infty} g(i_k),
\]
and this is just the Monte Carlo based method. On the other end, if \( \lambda = 0 \), the update rule (3.1) becomes

\[
J_{t+1} = (1 - \gamma_t)J_t + \gamma_t T J_t + \gamma_t \omega_t,
\]

where we use the fact that \( T \mu J_t = T J_t \). It is known that \( T \) is a weighted maximum-norm contraction (see Proposition 2.2 on p. 23 in [4]). General stochastic iterative algorithm result (see Proposition 4.4 on p. 156 in [4]) shows that the method converges to \( J^* \). For \( 0 < \lambda < 1 \), the method is kind of a weighted combination of \( T D(0) \) and Monte Carlo. We will show that it also converge to \( J^* \) almost surely in the rest of this section. We summarize our main result as follows:

**Theorem 3.1.** The sequence \( J_t \) generated by the optimistic synchronous policy iteration algorithm according to update rule (3.1) for the stochastic shortest path problem, converges to the optimal cost-to-go vector \( J^* \), almost surely.

Similar to the proof of Theorem 2.1, let us first establish several lemmas parallel to Lemma 2.3 to 2.5.

**Lemma 3.2.** The sequence \( J_t \) generated by optimistic policy iteration algorithm according to (3.1) is bounded almost surely.

**Proof.** We first show that for all policy \( \mu \), there exist a scalar \( \delta_{\mu} \in [0, 1) \), \( G_{\mu} > 0 \) and \( K_{\mu} > 0 \), the following estimates hold

\[
\| T^{k+1}_\mu J \| \leq \delta_{\mu} \| J \| + G_{\mu}, \quad \forall k > K_{\mu}, \forall J.
\]

To prove this, we notice that \( T_\mu \) is a contraction mapping with respect to some vector \( \xi_\mu \) with all components positive, i.e. there exists \( \beta_{\mu} \in [0, 1) \) such that

\[
\| T_\mu J - T_\mu \bar{J} \|_{\xi_\mu} \leq \beta_{\mu} \| J - \bar{J} \|_{\xi_\mu},
\]

for all vectors \( J \) and \( \bar{J} \) (see Proposition 2.2 on p. 23 in [4]). Thus

\[
\| T_\mu J \|_{\xi_\mu} \leq \| T_\mu J - J^{\mu} \|_{\xi_\mu} + \| J^{\mu} \|_{\xi_\mu}
\leq \beta_{\mu} \| J - J^{\mu} \|_{\xi_\mu} + \| J^{\mu} \|_{\xi_\mu}
\leq \beta_{\mu} \| J \|_{\xi_\mu} + D_{\mu},
\]

where \( D_{\mu} = (1 + \beta_{\mu}) \| J^{\mu} \|_{\xi_\mu} < \infty \). Inductively, we have

\[
\| T^{k+1}_\mu J \|_{\xi_\mu} \leq \beta_{\mu}^{k+1} \| J \|_{\xi_\mu} + (1 + \beta_{\mu} + \cdots + \beta_{\mu}^k) D_{\mu}, \quad \forall k \geq 0.
\]

This implies

\[
\| T^{k+1}_\mu J \|_{\xi_\mu} \leq \beta_{\mu}^{k+1} \| J \|_{\xi_\mu} + \tilde{D}_{\mu}, \quad \forall k \geq 0,
\]

where \( \tilde{D}_{\mu} = (\sum_{k=0}^{\infty} \beta_{\mu}^k) D_{\mu} < \infty \).

Let us denote by \( \xi_{\mu,\min} = \min_i \xi_{\mu}(i), \xi_{\mu,\max} = \max_i \xi_{\mu}(i) \) and set \( \rho_{\mu} = \xi_{\mu,\min}/\xi_{\mu,\max} \). Note that \( \rho_{\mu} > 0 \) and \( \beta_{\mu} \in [0, 1) \), thus there exists \( K_{\mu} > 0 \) such that \( \beta_{\mu}^{K_{\mu}+1} < \rho_{\mu} \). We
then have, for all \( k > K_\mu \)
\[
\|T^{k+1}_\mu J\| = \max_i \|T^{k+1}_\mu J(i)\| \\
= \xi_{\mu,\max} \max_i \left\{ \frac{|T^{k+1}_\mu J(i)|}{\xi_{\mu,\max}} \right\} \\
\leq \xi_{\mu,\max} \|T^{k+1}_\mu J\| \xi_{\mu} \\
\leq \xi_{\mu,\max} \left( \beta^{k+1}_\mu \|J\| + \tilde{D}_\mu \right) \\
\leq \xi_{\mu,\max} \xi_{\mu,\min}^{\beta^{k+1}_\mu} \|J\| + \xi_{\mu,\max} \tilde{D}_\mu \\
\leq \beta^{K_\mu+1}_\mu \|J\| + \xi_{\mu,\max} \tilde{D}_\mu \\
= \delta_\mu \|J\| + G_\mu,
\]
where \( \delta_\mu = \beta^{K_\mu+1}_\mu / \rho_\mu < 1 \) and \( G_\mu = \xi_{\mu,\max} \tilde{D}_\mu < \infty \). Set \( \delta = \max_\mu \delta_\mu \in [0, 1) \), \( G = \max_\mu G_\mu < \infty \) and \( K = \max_\mu K_\mu < \infty \), we then have
\[
\|T^{k+1}_\mu J\| \leq \delta \|J\| + G_\mu, \quad \forall k > K, \forall J, \forall \mu. \tag{3.4}
\]
On the other hand, it's easy to see that there exists a bounded scalar sequence \( \{G_k\}_{k=0}^K \), such that
\[
\|T^{k+1}_\mu J\| \leq \|J\| + G_k, \quad \forall k \leq K, \forall J, \forall \mu. \tag{3.5}
\]
Write
\[
J_{t+1} = (1 - \gamma_t)J_t + \gamma_t H_t J_t + \gamma_t \omega_t,
\]
where
\[
H_t J_t = (1 - \lambda) \sum_{k=0}^{\infty} \lambda^k T^{k+1}_\mu J_t.
\]
Given (3.4) and (3.5), the mapping \( H_t \) then satisfies the following estimates
\[
\|H_t J_t\| \leq (1 - \lambda) \sum_{0 \leq k \leq K} \lambda^k \|T^{k+1}_\mu J_t\| + (1 - \lambda) \sum_{k > K} \lambda^k \|T^{k+1}_\mu J_t\| \\
\leq (1 - \lambda) \sum_{0 \leq k \leq K} \lambda^k (\|J_t\| + G_k) + (1 - \lambda) \sum_{k > K} \lambda^k (\delta \|J_t\| + G) \\
= \phi_\lambda \|J_t\| + G_\lambda
\]
where
\[
\phi_\lambda = (1 - \lambda) \sum_{0 \leq k \leq K} \lambda^k + (1 - \lambda) \sum_{k > K} \lambda^k \delta < 1,
\]
and
\[
G_\lambda = (1 - \lambda) \sum_{0 \leq k \leq K} \lambda^k G_k + (1 - \lambda) \sum_{k > K} \lambda^k G < \infty.
\]
The boundedness of the sequence \( J_t \) then follows from Proposition 4.7 on p. 159 in [4]. \( \square \)

**Lemma 3.3.** For sequence \( c_t \) defined in (2.2), we have \( \limsup_{t \rightarrow \infty} c_t \leq 0 \).
Using affine properties of $T_{\mu_t}$, we have
\[ T_{J_{t+1}} \leq T_{\mu_t}J_{t+1} \]
\[ = T_{\mu_t} \left( (1 - \gamma_t)J_t + \gamma_t(1 - \lambda) \sum_{k=0}^{\infty} \lambda^k T_{\mu_t}^{k+1} J_t + \gamma_t \omega_t \right) \]
\[ = g_{\mu_t} + (1 - \gamma_t)P_{\mu_t}J_t + \gamma_t P_{\mu_t}(1 - \lambda) \sum_{k=0}^{\infty} \lambda^k T_{\mu_t}^{k+1} J_t + \gamma_t P_{\mu_t} \omega_t \]
\[ = (1 - \gamma_t)T_{\mu_t}J_t + \gamma_t T_{\mu_t} \left( \sum_{t=0}^{\infty} (1 - \lambda) \lambda^k T_{\mu_t}^{k+1} J_t \right) + \gamma_t P_{\mu_t} \omega_t \]
\[ = (1 - \gamma_t) (T_{\mu_t}J_t - J_t) + \left[ (1 - \gamma_t)J_t + \gamma_t(1 - \lambda) \sum_{k=0}^{\infty} \lambda^k T_{\mu_t}^{k+1} J_t + \gamma_t \omega_t \right] \]
\[ + \gamma_t \left[ T_{\mu_t} \left( \sum_{k=0}^{\infty} (1 - \lambda) \lambda^k T_{\mu_t}^{k+1} J_t \right) - \sum_{k=0}^{\infty} (1 - \lambda) \lambda^k T_{\mu_t}^{k+1} J_t \right] + \gamma_t [P_{\mu_t} \omega_t - \omega_t] \]
\[ = (1 - \gamma_t) (T_{\mu_t}J_t - J_t) + J_{t+1} + \gamma_t H_t J_t + \gamma_t v_t, \]
where
\[ H_t J_t = T_{\mu_t} \left( (1 - \lambda) \sum_{k=0}^{\infty} \lambda^k T_{\mu_t}^{k+1} J_t \right) - \sum_{k=0}^{\infty} (1 - \lambda) \lambda^k T_{\mu_t}^{k+1} J_t, \]
and
\[ v_t = P_{\mu_t} \omega_t - \omega_t. \]
Equivalently, we have
\[ T_{J_{t+1}} - J_{t+1} \leq (1 - \gamma_t) (T_{J_t} - J_t) + \gamma_t H_t J_t + \gamma_t v_t. \]
In the following context, we show that, for any $\epsilon > 0$, $H_t$ essentially is a maximum norm contraction with a unique fixed point $\epsilon e$, stochastic iterative algorithm then can be applied to (3.6).

We now fix an arbitrary $\epsilon > 0$. We notice that $T_{\mu_t}J^\mu_t = J_t$. Since $T_{\mu_t}$ is a continuous operator and we have only finitely many policies, we see that for this fixed $\epsilon$, there exists $\delta(\epsilon) > 0$, such that for all $\mu_t$, and all vector $J$, as long as $\|J - J^\mu_t\| < \delta(\epsilon)$, we have
\[ \|T_{\mu_t}J - J\| < \epsilon. \]
Now fix $\delta(\epsilon)$, since $\{J_t\}$ is bounded almost surely, by Lemma 2.2, there exists a positive integer $K(\epsilon)$, such that for all $k > K(\epsilon)$ and all $\mu_t$, the following estimates hold
\[ \|T_{\mu_t}^{k+1} J_t - J^\mu_t\| < \delta(\epsilon). \]
Now we split $H_t J_t$ to two parts according to $K(\epsilon)$ as
\[ H_t J_t = (1 - \lambda) \left[ \sum_{k=0}^{\infty} \lambda^k T_{\mu_t} (T_{\mu_t}^{k+1} J_t) - \sum_{k=0}^{\infty} \lambda^k T_{\mu_t}^{k+1} J_t \right] \]
\[ = H_{t,1} J_t + H_{t,2} J_t, \]
where
\[ H_{t,1} J_t = \sum_{k=0}^{K(\epsilon)} \lambda^k T_{\mu_t} (T_{\mu_t}^{k+1} J_t), \]
and
\[ H_{t,2} J_t = \sum_{k=K(\epsilon)}^{\infty} \lambda^k T_{\mu_t}^{k+1} J_t. \]
where in the first equality we apply Lemma \[1.5\] and

\[ H_{t,1}J_t = (1 - \lambda) \sum_{0 \leq k \leq K(\varepsilon)} \lambda^k (T_{\mu_1}(T_{\mu_1}^{k+1}J_t) - T_{\mu_1}^{k+1}J_t), \]

and

\[ H_{t,2}J_t = (1 - \lambda) \sum_{k > K(\varepsilon)} \lambda^k (T_{\mu_1}(T_{\mu_1}^{k+1}J_t) - T_{\mu_1}^{k+1}J_t). \]

Now we establish estimates for $H_{t,1}$ and $H_{t,2}$ separately.

(a) Estimate for $H_{t,1}J_t$ term: since

\[ T_{\mu_1}(T_{\mu_1}^{k+1}J_t) \leq T_{\mu_1}^{k+1}(J_t + c_t\varepsilon) \leq T_{\mu_1}^{k+1}J_t + c_t\varepsilon. \]

we have

\[ (3.9) \quad H_{t,1}J_t \leq (1 - \lambda) \sum_{0 \leq k \leq K(\varepsilon)} \lambda^k c_t\varepsilon = \varphi_1 c_t\varepsilon, \]

where $\varphi_1 = (1 - \lambda) \sum_{0 \leq k \leq K(\varepsilon)} \lambda^k$.

(b) Estimate for $H_{t,2}J_t$ term: since $k > K(\varepsilon)$, \(3.7\) holds. By the choice of $\delta(\varepsilon)$, we then have

\[ \|T_{\mu_1}(T_{\mu_1}^{k+1}J_t) - T_{\mu_1}^{k+1}J_t\| < \varepsilon, \]

this implies

\[ (3.10) \quad H_{t,2}J_t \leq (1 - \lambda) \sum_{k > K(\varepsilon)} \lambda^k \varepsilon = \varphi_2 \varepsilon, \]

where $\varphi_2 = (1 - \lambda) \sum_{k > K(\varepsilon)} \lambda^k$.

Combine \(3.8\), \(3.9\) and \(3.10\), we have

\[ (3.11) \quad H_tJ_t \leq \varphi_1 c_t\varepsilon + \varphi_2 \varepsilon. \]

Together with \(3.6\), we obtain

\[ (3.12) \quad T_Jt_{t+1} - J_t \leq (1 - \gamma_t) (T_Jt - J_t) + \gamma(t(\varphi_1 c_t\varepsilon + \varphi_2 \varepsilon) + \gamma tv_t. \]

Set $X_t = T_Jt - J_t$, by the definition of $c_t$, we see that

\[ X_{t+1} \leq (1 - \gamma_t)X_t + \gamma_t(\varphi_1 c_t\varepsilon \max_i X_t(i) + \varphi_2 \varepsilon) + \gamma tv_t. \]

We use the comparison argument as in previous section. Define a sequence of vector $Y_t$ by setting $Y_0 = X_0$ and

\[ Y_{t+1} = (1 - \gamma_t)Y_t + \gamma(t(\varphi_1 c_t\varepsilon \max_i Y_t(i) + \varphi_2 \varepsilon) + \gamma tv_t. \]

An easy inductive argument show that $X_t \leq Y_t$ for all $t$. Note that $\varphi_1, \varphi_2 \in (0, 1)$ and $\varphi_1 + \varphi_2 = 1$, it follows that $Y \mapsto \varphi_1 \varepsilon \max_i Y_t(i) + \varphi_2 \varepsilon$ is a maximum norm contraction, it’s well-known that there exists only one fixed point for this mapping. A straightforward calculation(using $\varphi_1 + \varphi_2 = 1$ ) shows that $\varepsilon$ is the fixed point for this mapping.

The rest of the proof is essentially identical to the argument in \[5\]. Fix a positive integer $l$, we define the stopped process $v^l(t)$ such that it coincides with $v_t$ as long as $E[|v_t|^2 F_t] \leq l$, and is equal to 0 thereafter. Consider the iteration

\[ Y_{t+1}^l = (1 - \gamma_t)Y_t^l + \gamma t(\varphi_1 c_t\varepsilon \max_i Y_t^l(i) + \varphi_2 \varepsilon) + \gamma tv_t^l. \]
By Proposition 4.4 in p. 156 of [4], $Y_l^t$ converges to $\varepsilon e$, for every $l$. Since $J_t$ is bounded, we see that $E[|v_t|^2|\mathcal{F}_t]$ is also bounded. Therefore, there exists some $l$ such that $v_l^t = v_t$ almost surely, as a result, $Y_l^t = Y_t$ for all $t$. Hence $Y_t$ also converges to $\varepsilon e$, which implies that

$$
\limsup_{t \to \infty} X_t \leq \varepsilon e.
$$

Note that $\varepsilon$ could be arbitrarily small, we conclude that

$$
\limsup_{t \to \infty} c_t \leq 0.
$$

□

We notice that, compared to (2.1), (3.1) replaces $J_{\mu t}$ by $(1 - \lambda) \sum_{k=0}^{\infty} \lambda^k T_{\mu t}^{k+1} J_t$. Corresponding to Lemma 2.5, we establish the following result

**Lemma 3.4.** For all $\varepsilon > 0$, there exists $t(\varepsilon) > 0$ such that for all $t \geq t(\varepsilon)$, we have

$$
(1 - \lambda) \sum_{k=0}^{\infty} \lambda^k T_{\mu t}^{k+1} J_t \leq T J_t + \varepsilon e.
$$

**Proof.** First we notice that the conclusion in Lemma 2.5 still holds for $J_t$ generated by update rule (3.1). If we examine the proof closely there, in order to prove Lemma 2.5 for $J_t$, we only need the boundedness of $J_t$ and $\limsup_{t \to \infty} c_t \leq 0$, and it does not depend on how we update $J_t$. Both of the facts hold for $J_t$ generated here.

By Lemma 2.5, we know for any fixed $\varepsilon > 0$, there exists a time $t_1(\varepsilon)$, for all $t > t_1(\varepsilon)$, we have

$$
J_{\mu t} \leq T J_t + \frac{\varepsilon}{2} e.
$$

For this fixed $\varepsilon > 0$, since $J_t$ is bounded, by Lemma 2.2 there exists a positive $K(\varepsilon)$, for all $k > K(\varepsilon)$ and policy $\mu_t$, we have

$$
T_{\mu t}^{k+1} J_t \leq J_{\mu t} + \frac{\varepsilon}{2}.
$$

Combine above two inequalities, we have

$$
T_{\mu t}^{k+1} J_t \leq T J_t + \varepsilon, \quad \forall t > t_1(\varepsilon), \quad \forall k > K(\varepsilon).
$$

Note that

$$
T_{\mu t}^{k+1} J_t \leq T_{\mu t} J_t + k c_t e = T J_t + k c_t e,
$$

also note $\limsup_{t \to \infty} c_t \leq 0$, we see that for this fixed $K(\varepsilon)$, there exists $t > t_2(\varepsilon)$, such that $K(\varepsilon) c_t < \varepsilon$. This implies

$$
T_{\mu t}^{k+1} J_t \leq T J_t + \varepsilon, \quad \forall t > t_2(\varepsilon), \quad \forall k \leq K(\varepsilon).
$$

Set $t(\varepsilon) = \max\{t_1(\varepsilon), t_2(\varepsilon)\}$, (3.14) and (3.15) then implies

$$
T_{\mu t}^{k+1} J_t \leq T J_t + \varepsilon, \quad \forall t > t(\varepsilon), \quad \forall k.
$$

Given (3.16), for all $t > t(\varepsilon)$, we have

$$
(1 - \lambda) \sum_{k=0}^{\infty} \lambda^k T_{\mu t}^{k+1} J_t \leq \left( (1 - \lambda) \sum_{k=0}^{\infty} \lambda^k \right) (T J_t + \varepsilon) = T J_t + \varepsilon.
$$

□

Having established all these preliminary results, let us prove our main theorem
Proof of Theorem 3.1. The proof is essentially the same as in proof of Theorem 2.1. We fix some $\epsilon > 0$, by Lemma 3.4, there exists $t(\epsilon)$ such that estimates (3.13) hold. We then have

$$J_{t+1} \leq (1 - \gamma_t)J_t + \gamma_t(TJ_t + \epsilon) + \gamma_t \omega_t, \quad \forall t \geq t(\epsilon).$$

The rest of the proof is then identical to the last part of the proof in Theorem 2.1. \Box
