Abstract

Hepatocellular carcinoma (HCC) is the most common primary malignancy of the liver and the second leading cause of cancer mortality worldwide. Many strategies to discover molecular-based therapy are currently being implemented to overcome the resistance in HCC treatment. Cancer research is more targeted at molecular level of natural ingredients treatment as chemoprevention to reduce carcinogenesis risk. One of the natural compounds that serve as chemopreventive agent is mangosteen. α-Mangosteen, a xanthone commonly found in the fruit hull of Garcinia mangostana Linn, possess as an antioxidant. This study aims to determine the levels of reactive oxygen species (ROS), malondialdehyde (MDA), and protein carbonyl (PC) as the biomarkers of oxidative stress on untreated HepG2 cells compared to α-mangosteen-treated HepG2 cells. The results indicated that α-mangosteen has a cytotoxic effect on HepG2 cells with IC₅₀=242.58 µg/mL and reduced ROS level 23.15±4.29% at 200 µg/mL. The MDA level of HepG2 cells was not significantly higher than on WRL-68 by 7.6%, 17.93%, 28.8%, 35.32%, and 61.95% at 100, 200, 500, 800, and 1000 µg/mL respectively. α-Mangosteen at 100 and 200 µg/mL reduced protein carbonyl by 76.24 and 79.84% in HepG2 cells line while compared to normal liver cells line (WRL-68) significantly (P<0.05). In conclusion, α-mangosteen reduced levels of ROS, MDA and PC. Therefore, α-mangosteen is a potential anti-cancer agent through oxidative stress inhibition.

Keyword: free radical, HepG2 cells, α-mangosteen, oxidative stress.

INTRODUCTION

Hepatocellular carcinoma (HCC), one of the liver cancers, is the most common malignant liver and the second leading cause of cancer mortality worldwide. According to US surveillance, epidemiology, and results (SEER) database program, HCC accounts for 65% of all cases of liver cancers. The incidence rate of HCC increased from 1.4/100,000 cases/year between 1976–1980 to 6.2/100,000 cases reported in 2011 and predominant in Asian countries (Ghouri, et al., 2017). A study in Indonesia revealed that the mortality rate of patients with HCC in Cipto Mangunkusumo National General Hospital was 48.2% (Jasirwan, et al., 2020). Chronic infection with hepatitis B and C virus is one of the high-risk conditions leading to HCC. As no obvious sign or symptom, the tumor is
hard to diagnose at first and able to detect after the
tumor become large. The treatment and survival rate
of patients-diagnosed with HCC is doubtful (Gani,
2017). Also, the efficacy of treatment was limited
and needed more understanding of patient who
could obtain the benefit of treatment. Resistance
also occurs in first-line or single drug. The altered
pathways within cells is fundamental caused of
tumorigenesis, the metastatic process, and stem cell
properties disturbance (Le Grazie, et al., 2017).

Many strategies for selecting the molecular-based
therapy are currently being implemented
to overcome the resistance in HCC treatment. Nowadays, cancer research is targeted to potential
natural ingredients toward molecular mechanism
as chemoprevention agent in order to reduce
carcinogenesis risk. Chemoprevention is a rapidly
developing focus of oncology that focuses on the
cancer-preventive strategy by natural or synthetic
interventions (Manimekalai, et al., 2016).

Cellular macromolecule disruption, such as
DNA, proteins, lipids, and carbohydrate is a result
of oxidative modification induced by oxidative
stress (Liguori, et al., 2018). Prolongation of the
disruption could increase the risk of several chronic
diseases, such as cancer, autoimmune diseases,
cardiovascular diseases, neurodegenerative
diseases, mental disorders, and skin aging. For
minimizing the risk, antioxidants are needed which
are compounds that could stabilize free radicals
by hydrogen atoms donation mechanism, low-
density lipoprotein (LDL) oxidation inhibition,
and metal ions chelation. The stabilization of
free radicals by antioxidants could prevent and
repair DNA damage (Elmund, 2020). The study of
chemoprevention mechanism is often associated
with antioxidant properties, redox, and anti-
inflammatory molecules contained in natural active
ingredients (Tan, et al., 2011; Bose, et al., 2020).
One of the naturals compounds that possesses as
chemopreventive agent is mangosteen. Mangosteen
(Garcinia mangostana Linn) family of Guttiferae,
is one of the fruits that widely grows in Southeast
Asia. The fruit flesh is soft and white which also
contain high sugar and low protein. The oil of
mangosteen seeds contain essential fatty acids
such as linoleic (1.3%), palmitic (49.5%), and
oleic (34%) (Quan, et al., 2012). Previous studies
reported Garcinia mangosteen as a potent source of
natural antioxidants which are a great therapeutic
agent by preventing or slowing down the progress
of aging, age-associated oxidative stress, and
related degenerative diseases. Mangosteen extracts,
products, and isolated compounds showed to rise
antioxidant levels through in vivo studies by either
increasing antioxidant enzymes (such as SOD,
CAT, GPx, and GSH) or decreasing oxidative
stress markers (such as MDA level) (Manimekalai,
et al., 2016). However, there is few information
corelated with reactive oxygen species (ROS),
malondialdehyde (MDA), and protein carbonyl
(PC) carbonyl proteins within HCC. This study
aims to determine the levels of ROS, MDA, and PC
as oxidative stress biomarkers on untreated HepG2
cells compared to α-mangosteen-treated HepG2.
The results can be used as fundamental literature
for further research.

MATERIAL AND METHODS

Material

The HepG2 human hepatoblastoma cancer
cell lines and WRL-68 human hepatocyte normal cell
lines were purchased from ATCC (Rockville, MD,
USA). Eagle’s minimum essential medium (EMEM)
(Gibco, New York, USA) was supplemented with
10% fetal bovine serum (Biowest, Riverside, USA),
5% amphotericin, and 5% penicillin-streptomycin
(Biosciences, San Jose, USA). α-Mangosteen was
purchased from Chromadex (Irvin, CA) with 95% purity. The MTT kit was obtained from Promega
(Madison, USA). The DCFDA-Cellular Reactive
Oxygen Species kit was obtained from the Abcam
Mito Sciences catalog no 113851.
Cell Culture
The HepG2 and WRL-68 cells were cultured in a tissue flask containing EMEM complex growth medium to obtain a confluency of 70–80%. After the cells were harvested, the cells were counted using a haemocytometer. Cells were used for about $1\times10^6$ cells/a well, then treated α-mangosteen which had dissolves in DMSO.

Cytotoxicity Assay
The cytotoxicity assay based on colorimetric principle under MTT Assay. Cells ($5\times10^3$ per well) were plated in 96 well-plates and treated for 24 h with α-mangosteen concentrations of 0, 100, 200, 500, 800, and 1000 µg/mL. Additionally, 0.1% DMSO was also used as a control. Cell viability analysis was done using MTT assay (Promega, Madison, WI, USA) according to manufacturer’s instruction. Absorbance was measured at 570 nm using a 96-well plate reader. Cytotoxic analysis of α-mangosteen samples on cells was carried out by calculating a 50% cell inhibition concentration ($IC_{50}$) based on triplicate data.

Preparation of Reactive Oxygen Species (ROS), Malondialdehyde (MDA), Protein Carbonyl Analysis
Prior the analysis, cells ($1\times10^8$) treated with α-mangosteen, then washed three times using 200 µL of cold 50 mM phosphate buffer solution, pH 7.0. Cell suspension was centrifuged at a speed of 600 rpm for 10 minutes at 40°C and the supernatants were discarded. Then the cell pellets were being suspended in a cold 50 mM phosphate buffer solution, pH 7.0 (1:2). The cell homogenate was subsequently solved using a sonicator for 2 minutes at 40°C. Furthermore, the suspension of this cell was centrifuged again at a speed of 10,000 rpm for 10 minutes at 40°C. The supernatant was collected and stored in a cold freezer -20°C to be used for the analysis of ROS, MDA, and protein carbonyl respectively.

Cellular Reactive Oxygen Species (ROS) Analysis
Examination of ROS activity was carried out by ELISA following protocol of Abcam Mito Sciences catalogs No. 113851. After 2,7-dichlorofluorescein diacetate (DCFDA) reagent diffused into the cell, the DCFDA will be deacetylated by cellular esterase enzyme. Then it became a non-fluorescent compound and immediately oxidized by ROS from to 2,7-dichlorofluorescein (DCF) compounds which was detected in fluorescent spectroscopy on a plate reader at excitation/emission of 485 nm/535 nm. ROS levels of HepG2 and WRL-68 cells were treated by α-mangosteen at a concentration of 5, 10, 50, 100, 200, 500, and 1000 µg/mL.

Measuring of Malondialdehyde (MDA) Levels
The formation of MDA as a result of lipid peroxidation reactions can be analyzed by detecting red mixture through the thiobarbiturate (TBA) form under spectrophotometry. The standard curve is determined through compound 1.1.3.3-tetraetoxy propane (TTHP), where 100 µM TTHP solution was dissolved with distilled water to exactly contain 1, 2, 5, 10, and 20 µM in each solutions. Subsequently, 1.5 mL of a 0.8% solution of thiobarbituric acid (in 20% acetic acid) was added. All the tubes were then put into a boiling water bath for 60 minutes. Then let it cold for 10 minutes. After that, every 1.5 mL from each tube transferred into the cuvette and read at a wavelength of 532 nm under spectrophotometry.

Protein Carbonyl (PC) Measurement
The PC measurement indicated of protein oxidation due to high levels of ROS within cells. The presence of redox cations such as Fe (II) or Cu (II) can be bound to cell proteins which then react with free radicals (hydrogen peroxide) to change the amine groups of side chains of amino acids (Lys, Arg, Pro, or His) to form carbonyl. This carbonyl reaction with 2.4 dinitrophenyl hydrazine
(DNPH) reagent will form the Schiff base which then forms hydrazone and can be measured by spectrophotometry at wavelengths of 360–385 nm. Supernatant were diluted 1 per 4 with saline buffer solution pH 7.4 and centrifuged at 14,000 rpm for 10 minutes. The dissolved protein was then stored within a solution of 20% trichloroacetic acid (TCA) and centrifuged again for 5 minutes. Then added 10 mM DNPH in 2 N HCl and left for 1 h in a dark room with shaking every 10 minutes. This mixture was added with 6 M guanidine hydrochloride and given 2 N HCl left for 15 minutes at 37ºC using the vortex. The PC content was determined by spectrophotometrically at a wavelength of 366 nm with a molar coefficient of 22,000/MCm⁻¹.

**Statistical Analysis**

The results are illustrated as mean±standard deviation from three experiments where each experiment was triplicate. The statistical data is established by Student t-test with the degree of toughness \( p < 0.05 \).

**RESULT**

**α-Mangosteen Cytotoxicity Assay**

Under cytotoxicity assay, the integrity of mitochondrial cells could be seen as methylene blue form in result of reduction by dehydrogenase enzyme during cell metabolism under MTT Assay. The more rapid of blue color forming indicates the ability of cells to metabolize well. Treatment with α-mangosteen within cell growth medium also influenced the process of reducing methylene blue that is proportional to the number of living cells that depict cells viability. The IC\(_{50}\) value of HepG2 cells is 242.5837 µg/mL, whereas in WRL-68 is 285.2718 µg/mL.

According to IC\(_{50}\) value, α-mangosteen shows more toxic to liver cancer cells HepG2 compared to normal liver cells WRL-68. Figure 1. Liver cancer cells contain oxidative stress than those found in normal liver cells (Barrera, 2012). Treatment with α-mangosteen added more antioxidant, hence it can inhibit the mechanism of free radical formation.

![Figure 1. Cytotoxicity effect of α-Mangosteen on cancer cell (HepG2) and normal hepatocyte cells (WRL-68).](image)

The results are presented in the average values±standard deviations of three different repetitions in which each work is done triplicate.

A comparison cells treated with α-mangosteen from various concentrations and control(*\( p < 0.05 \)) in HepG2 cells and (#\( p < 0.05 \)) in normal hepatocyte cells (WRL-68).

a) Significantly difference compared to 40 µg/mL (\( p < 0.01 \)) in HepG2 cells
b) Significantly difference compared to 40 µg/mL (\( p < 0.01 \)) in WRL-68 cells
c) Significantly difference between HepG2 and WRL-68 cells at 800 µg/mL (\( p < 0.05 \))
The results indicated that α-mangosteen able to inhibit the formation of ROS within HepG2 cells under triplicate experiment. The concentration of 200 µg/mL α-mangosteen (concentration approaching IC$_{50}$ value) was able to inhibit ROS formation in HepG2 was 23.15±4.3% compared to WRL-68 of 23.2±2.1%.

**Cellular ROS Analysis**

The antioxidant properties contained in α-mangosteen can eradicate free radical reactions through three mechanisms, namely (1) neutralization by antioxidant enzymes; (2) termination of the initial chain by antioxidants instead of enzymes; and (3) chain termination through binding to transition metal ions (Cu2+, Fe2+) by plasma proteins.

Based on antioxidant properties, α-mangosteen can be used as an anti-cancer compound to inhibit cell growth as cancer cells have high levels of oxidative stress. Therefore, giving antioxidants toward cancer cells can reduce oxidative stress. Antioxidant properties also induce apoptotic and regulate both of signal transduction molecules and cell redox molecules leading to inhibit cancer cells proliferation (Figure 2).

**Mangosteen Effect on Malondialdehyde (MDA) Levels of Cancer Cells**

The decline of MDA levels both in HepG2 and WRL-68 cells after treated with α-mangosteen was not significant. Based on Figure 3, α-mangosteen treatment more able to inhibit MDA formation in HepG2 rather than in WRL-68 at the concentration above 500 µg/mL. This might be the oxidative stress level is higher in liver cancer cells than in normal cells. The α-mangosteen exhibited more antioxidant properties causing inhibition of the free radicals’ formation such as MDA which is the end-product of lipid peroxidation.

**DISCUSSION**

Various kinds of xanthones in *Garcinia mangostana* L. have been proven for having a strong antioxidant feature including α-mangosteen. The α-mangosteen is a yellowish-compound which can be obtained from the other parts of the plant.
as well, such as the dried sap and the bark. This compound has been discovered to possess a wide range of biological activities, such as antioxidant, anti-inflammatory, anti-tumor, and anti-bacterial and anti-obesity agents. The cytotoxic effects of α-mangosteen in cancer cells (HepG2) and normal hepatocyte cells (WRL-68) were determined by MTT assay. The α-mangosteen treatment showed dose-dependent toxicity toward HepG2 and WRL-68 after 24 h incubation with IC\textsubscript{50} values are 242.5837 and 242.5837 respectively. In the other hand, Manimekalai \textit{et al.}, 2016 stated the IC\textsubscript{50} after treated with chloroform extract and hexane extract epicarp on HepG2 cells were 50 µM and 5.25 µM respectively. Adenina, \textit{et al.}, 2020 also stated the IC\textsubscript{50} of α-mangosteen was 23.74 µM under MTS assay. The distinct result might be influenced by cells passage, treatment concentration, micronutrient factor, and redox properties within HepG2 cells (Adenina, \textit{et al.}, 2020).

ROS is constantly formed within cells and tissues that can be prevented by antioxidant defense system. The cellular antioxidant properties of mangosteen disturbances free radical reactions in 5 ways, namely (1) inhibition of ROS formation; (2) termination of the initial ROS chain and its precursors; (3) chain termination through binding to transition metal ions (Cu²⁺, Fe²⁺) by plasma proteins (4) up-regulation of the antioxidant enzyme system; and (5) maintain thiol group (-SH) from oxidizing (He, \textit{et al.}, 2017). Oxidative disruption of enzymes and protein structure exhibits progression of the disease. Protein carbonyls formed by oxidation also serves as markers of oxidative

Figure 3. The MDA level of α-Mangosteen on cancer cells (HepG2) and normal hepatocyte cells (WRL-68).

Figure 4. α-Mangosteen effect of carbonyl protein in cancer cells (HepG2) and normal hepatocyte cells (WRL-68). Statistically significant (*P<0.05) vs control in HepG2 and (#P<0.05) vs control in WRL-68.
disruption within protein (Wong, et al., 2013). In this study, we analyzed ROS induction after treated with α-mangosteen on HepG2 cells through DCFDA assay. The result shows the increase of inhibition ROS levels after treated with α-mangosteen on HepG2 cells in a dose-dependent trend. In addition, protein can also be interfered by massive reaction of ROS. Baek, et al. (2021) reported mangosteen at 2.5 and 10 μM could reduce ROS levels in neuronal cells HT22 based on the DCFDA assay and reduce ROS as result of glutamate illustrated by fluorescents (Baek, et al., 2021).

The manifestations of oxidative stress are biomolecular impairment, induction of apoptosis, and tissue damage. The lipid peroxidation occurs due to accumulation of reactive electrophile species such as epoxide and aldehydes which malondialdehyde is the main product of lipid peroxidation. This hypothesis explained that the formation of MDA in vivo is a result of lipids oxidation from two or more double bonds. In addition, MDA formed through the byproducts of free radical formation due to ionization radiation and prostaglandin biosynthesis (Lykkesfeldt, 2007). MDA compounds can be mutagenic and carcinogenic which also can react with alkaline nitrogen from nucleic acid (DNA) at physiological pH to form dG, da, and dC. This form resembles the reaction of carbonyl groups with N2 and N1 from dG which losing water molecules (H2O) in order to produce pyrimidopurinon, M1G (Barrera, 2012). The result proves that α-mangosteen-treated HepG2 cells could increase MDA levels in a dose-dependent trend. MDA is the organic compound-end product of lipid peroxidation from polyunsaturated fatty acids that induces oxidative stress. In this study, the MDA level HepG2 and WRL-68 cells subjected with α-mangosteen was evaluated. The result shows MDA level significantly increased in WRL-6 cells compared to HepG2 cells. This result indicated that the level of oxidative stress on liver cancer cells is higher than normal cells.

Among these reactions, carbonylation has attracted a great deal of attention due to its irreversible and unrepairable properties. Carbonylated proteins are marker of proteolysis which induced by the proteasome and the protease, but able to evade the degradation process and form a huge molecular aggregates that accumulated during aging. Several pathways of protein carbonylation are the conjugation with reactive carbonyl species and direct metal-catalyzed oxidative attack on amino acid residues. Protein carbonylation might contribute on organelle-specific signals formation and protein condition. The subsequent oxidative stress not only causes cell damage but also contributes lipids and proteins oxidation, including protein carbonylation. Alter of protein carbonyl formation correlated with free radicals production within HepG2 cells (Chienwichai, et al., 2019).

According to antioxidant properties of mangosteen, it can also be used as an anti-cancer agent to inhibit cancer cell growth as cancer cells contain high oxidative stress,. Therefore, giving antioxidants to cancer cells can reduce oxidative stress occurrence. The antioxidant activity of mangosteen can also be used as apoptosis inducer. Moreover, antioxidants are also able to regulate signal transduction molecules such as Bax, Caspase 8, Caspase 3, NFκβ transcription factors, and cell redox molecules such as NADH, Glutathione which induce apoptosis to halt cancer cell proliferation (Cazzaniga & Bonanni, 2012).

**CONCLUSION**

From this study can be concluded that α-mangosteen reduced ROS levels, MDA and PC both in HepG2 and WRL-68 cells. Thus, α-mangosteen is a potential anti cancer agent through inhibition of oxidative stress.
