Abstract

Objective: To study the peculiarities of anesthesia-resuscitation and the prognostic factors of morbidity and mortality of eclampsia in the intensive care unit of the Saint Louis regional hospital in Senegal. Type of Study: Retrospective descriptive and analytical study over one year. Materials and Method: All patients admitted to resuscitation for management of eclampsia from 1 January to 31 December 2018 were included. We studied the clinical, therapeutic, evolutionary and prognostic factors of morbidity and mortality. Results: We collected 51 cases of eclampsia for 5000 deliveries in the study (incidence of 1%). The average age of the patients was 22.23 years. Primiparity was found in 28 patients (54.9%). Antenatal consultations were effective in 4 patients (7.8%). Consciousness was clear at admission in 42 patients (82.36%) and for one patient a Glasgow score < 8 was reported (1.96%). Severe hypertension was observed in 27.4% of cases. A ventilation intubation of 03 days was required in one patient in 1.9% of cases. Caesarean was the mode of delivery in 56.8% of cases and vaginal delivery was performed in 43% of cases. General anesthesia was doing in 20 patients (68.9%) and spinal anesthesia was performed in 9 patients (31%). Maternal complications were represented by: Postpartum acute renal failure (13.7%), Hellp syndrome (11.7%), coagulopathy (15.6%). Prematurity was found in 14 neonates (13.7%), perinatal mortality was 9.8% and the maternal mortality rate was 5.8%. Conclusion: Eclampsia is still responsible for high maternal and infant mortality. The association of two or even more serious factors is very important in this mortality.

Keywords: Eclampsia; Anesthesiology; Prognostic factors of morbidity and mortality.

INTRODUCTION

Eclampsia, a major neurological complication of pre-eclampsia, is defined by a convulsive manifestation and/or consciousness disorder occurring in a preeclampsia context and cannot be attributed to a pre-existing neurological problem [1]. The severity of this pathology is correlated with visceral neurological, renal, hepatic and/or hematological involvement. The morbidity and mortality of eclampsia is still high in rural Africa [2].

The objective of this study was to evaluate the clinical aspects, the therapeutic management, the evolutionary aspects and the prognostic factors of morbidity and mortality of eclampsia in the intensive care unit of the regional hospital of Saint Louis in Senegal.

MATERIAL AND METHOD

This is a retrospective, descriptive and analytical study of all patients admitted for eclampsia from January 1 to December 31, 2018 in the multipurpose intensive care unit of the Saint Louis regional hospital in Senegal. Patients were admitted from the maternity hospital or from peripheral health facilities. The diagnosis of eclampsia was based on the occurrence of peripartum seizures in a woman whose history and examination revealed no other cause for the convulsion. All patients with eclampsia were treated according to the management protocol, namely: stabilization (peripheral venous catheters, oxygen therapy, Guedel cannula, lateral safety position, standard monitoring), administration of 4 g SMgO4 in
The descriptive analysis was done on Epi-Info 7.1 and the illustrations on Excel 2016. The analysis was univariate then bivariate. The alpha was set at 5%, that is, the p-value was considered significant whenever it was less than 0.05. Prolonged endotracheal intubation (3 days) was necessary in one patient, or in 1.9% of cases.

RESULTS

A total of 51 cases of eclampsia for 5000 deliveries were treated during this period, i.e. an incidence of 10 cases of eclampsia / 1000 deliveries. The mean age of the patients was 22.23 years, with a range of 14 to 36, and a standard deviation of 5.59. The most represented age group was 14-19 years old, in 39.2% of cases. Primiparity was found in 28 patients, 54.9% of the time. The prenatal consultations were effective in 4 patients, in 7.8% of the cases. Pregnancy was conducted to completion for 20 patients in 39% of cases. The patients came from the maternity ward in 47.1% (24 cases) and peripheral health facilities in 52.9% (27 patients). The first episodes of seizures occurred in antepartum in 31 patients, in 61% of cases. In 20 patients the seizure was reported postpartum, i.e. in 39% of cases. In our series, 24 patients had their first seizure in the obstetrics and gynecology department, 47% of the time, and in 15 patients, the anamnesis had a convulsive seizure at home (29.4%). Consciousness was clear at admission (15/15 Glasgow score) in 42 patients, i.e. in 82.36% of cases, and a coma was reported in one patient (Glasgow score <8), i.e. in 1.96 % of cases. At admission, minimal arterial hypertension (defined as PAS between 140 and 159 mmHg and / or PAD between 80 and 89 mmHg according to the NYHA classification) was observed in 10 patients, i.e. in 19.6% of cases. Moderate arterial hypertension (PAS between 160 and 179mmHg and / or a DBP between 90 and 99mmHg, according to the NYHA) was found in 15 patients, i.e. in 29.4% of cases. Severe arterial hypertension (NO greater than or equal to 180mmHg and / or PAD greater than or equal to 100mmHg according to NYHA) was objectified in 14 patients, i.e. in 27.4% of cases. However, the blood pressure at admission was normal in 12 patients, i.e. in 23.5% of cases. Oliguria and / or oligo-anuria defined by diuresis <0.5 ml / kg / ha was observed in 6 patients, i.e. in 11.7% of cases and proteinuria greater than 2 crosses was found in 10 patients, i.e. in 19.5% of cases. The maintenance treatment consisted of the administration of 1g / h of magnesium sulphate in 45 patients, i.e. in 88.2% of the cases. However, diazepam in an electric syringe was necessary in 3 patients, i.e. in 5.8% of cases. Nicardipine monotherapy with an electric syringe was used in the treatment of hypertension in 20 patients, i.e. in 39.2% of cases and a combination therapy (Nicardipine-clonidine) was required in one patient, i.e. in 1.9% of cases. Endotracheal intubation of 3 days was necessary in one patient, i.e. in 1.9% of cases.

Caesarean sections were performed in 29 patients, i.e. 56.8% of the time, and vaginal delivery was reported in 22, i.e. 43% of the cases. General anesthesia was the anesthetic technique of choice in 20 patients, i.e. in 68.9% of cases and spinal anesthesia was performed in 9 patients, i.e. in 31% of cases. Postpartum acute renal failure was found in 7 patients, i.e. in 13.7% of cases. The Heli p syndrome was noted in 6 patients, i.e. in 11.7% of cases, coagulopathy was reported in 8 patients or in 15.6% of cases, hemorrhagic stroke and magnesium sulfate overdose (via slow intravenous calcium administration) were found in one patient respectively, i.e. in 1.9% of cases respectively. The evolution has objectified 3 cases of death, a mortality rate of 5.8%. Prematurity was found in 14 neonates, i.e. in 13.7% of cases and perinatal mortality in 5 out of 51 cases, i.e. a perinatal mortality rate of 9.8%. Acute fetal distress and prematurity were the causes of death in 60% and 20% of cases, respectively.

In bivariate analysis, pregnancy was associated with the occurrence of a HELLP syndrome (p-value = 0.02) and the occurrence of stroke-type complications (p-value = 0.01). Multiparity was also associated with coagulopathy and HELLP syndrome (p-value = 0.02). The altered state of consciousness (Glasgow score <15) was associated with acute renal failure (p-value = 0.01 and the combination of complications of IRA + coagulopathy (p-value = 0.005).) Maternal mortality was also associated with cerebro-meningeal hemorrhage, complications of IRA + HELLP syndrome (p <0.05) and coagulopathy (p> 0.05).
Table-1: Distribution of complications as a function of evolution

| Complications                        | Number of parturients | Evolution : Favorable death | Percentage |
|--------------------------------------|-----------------------|-----------------------------|------------|
| Acute renal failure                  | 7                     | 7                           | 13.7%      |
| Hellp syndrome                       | 6                     | 6                           | 11.7%      |
| Acute renal failure + Hellp           | 2                     | 2 (p < 0.05)                | 3.9%       |
| Coagulopathy                         | 8                     | 7                           | 15.6%      |
| Cerebro-meningal hemorrhage          | 1                     | 1 (p < 0.05)                | 1.9%       |
| Overdose with magnesium sulphate     | 1                     | 1                           | 1.9%       |

Hellp: Hemolysis, Elevated Liver enzymes, Low Platelet count

DISCUSSION

Eclampsia is a serious complication of pre-eclampsia that can be life-threatening. The annual incidence of eclampsia in Saint Louis remains high at the rate of 10 cases / 1000 deliveries, i.e. in 1% of cases. The analysis of literature data found a variable incidence in developing countries with an incidence of 1.4% in Dakar [2] and 0.3% in the Brazzaville study [3]. Even in countries where pregnancy monitoring is considered good, eclampsia is not an uncommon pathology: its incidence is about 2.5 to 3.10^-5 in Sweden or Great Britain and higher in the United States at 1210^-5 [4]. In France, G. Ducarme and colleagues found an incidence of eclampsia of 0.8% per year [5]. The risk factors for eclampsia are similar to those of preeclampsia without other specificities. They are abundantly described in literature but do not enable the detection of women at risk. The absence of risk factors does not eliminate the possibility of presenting with the complication. The main risk factors are young age and the lack of medical follow-up during pregnancy. Therefore, the surveillance of pregnant women remains the best weapon of prevention, as it makes it possible to detect the onset of pregnancy-related hypertension and pre-eclampsia [6]. Indeed in our study the high incidence of eclampsia compared to the developed countries is certainly related to the low percentage of medical monitoring of our parturients, which was 7.8%. In our study, as also found in literature, eclampsia presents itself as a pathology of young primiparous women [7]. Eclampsia is a complication of pre-eclampsia that is secondary to a defect of trophoblastic invasion in the myometrium during placentation, leading to a lack of tissue oxygenation. This pathology can therefore occur throughout the peripartum period from the twentieth week of amenorrhea.

Most cases of eclampsia occur pre- or peripartum, often before arrival at the hospital [8]. Early onset eclampsia (before the 32nd week of amenorrhea) seems to have a poorer prognosis [9]. Postpartum eclampsia occurs most often within 48 hours, but sometimes much later. For some, these cases of postpartum eclampsia are less serious in terms of associated pathologies (HRP, HELLP) [9]. In our study, eclampsia is usually established prepartum and there is no statistically significant relationship between postpartum eclampsia and decreased maternal complications. However, it should be noted that in prepartum eclampsia the use of SMgO4 promotes the neuroprotection in prematurity before the 33rd week of gestation, hence the importance of the use of this molecule for prepartum eclampsia [10]. The choice of SMgO4 as first-line treatment for pre-partum eclampsia is justified for its antiepileptic properties, prevention of recurrent seizures, and neuroprotection for the fetal brain [10]. Its mechanism of action seems adapted to the pathophysiology of posterior reversible encephalopathy (PRES syndrome), which remains a rare event in the evolution of eclampsia [11]. In our series the management protocol certainly recommends the use of SMgO4 for cases of prepartum eclampsia, but our data have not made it possible to study its effects of fetal neuroprotection.

The preferred route of childbirth remains, for many authors, a caesarean section [9] as was the case in our study. The choice of anesthetic technique for caesarean section in case of eclampsia remains
General anesthesia has risks such as difficult intubation, inhalation, hypertensive response of laryngoscopy and intubation, and multiple drug interactions. Spinal anesthesia also has risks such as extensive motor block, convulsions during the procedure, increased sensitivity to vasopressors to correct hypotension and cerebral involvement due to dural puncture in case of severe intracranial hypertension [12]. In case of eclampsia, locoregional anesthesia is possible if the patient is conscious, has no neurological deficit, has a stable clinical condition and no thrombosis. On the other hand, general anesthesia is recommended in case of subintubative convulsions with disturbances of consciousness. In this case, induction is performed with thiopental. Finally, pre-eclampsia is accompanied by an exacerbation of the edema of the upper respiratory tract. These women must therefore be considered systematically as at risk for difficult intubation and laryngeal obstruction for extubation [13]. Finally, rapid evacuation of the uterus has been shown to significantly reduce maternal and infant mortality following eclampsia [2].

In our study, the high rate of general anesthesia is explained by the fear of performing spinal punctures in case of coagulopathy or thrombocytopenia, especially because delays in obtaining blood sample results (NFS, TP) do not favor this risk taking. However, no case of Mendelson's syndrome was seen. Eclampsia is the ultimate stage of the Vasculo-renal complications of pregnancy. It is a systemic accident that is usually accompanied by a series of complications, making the prognosis even more unfavorable. Coagulopathy (15.6%), HELLP syndrome (11.7%), acute renal failure (13.7%), and stroke (1.9%) are often found by other authors; their frequency seems to be high in antepartum [14]. But rather than considering isolated complications, it is the associations of complications that are real prognostic factors of mortality. In our study the IRA-Hellp syndrome pair was significantly associated with mortality (p <0.05). Maternal mortality linked to eclampsia is currently low in European countries (between 0 and 1.8%) thanks to rapid and adapted care, but varies between 14 and 15.6% in developing countries [6]. The maternal mortality in our study is certainly high (7.8%) but remains lower than the high mortality rates found in other studies in sub-Saharan Africa [2] because the use of cesareans is easier and access to dialysis, as in our center, allows better management of kidney failure. However, in our center in particular and in Africa in general, the improvement of technical platforms, and medical follow-up of the parturients are prerequisites for the improvement of the prognosis of eclampsia.

The prognosis of the newborn is directly related to gestational age and postnatal care [6]. Perinatal mortality and morbidity are still high with perinatal mortality ranging between 6 and 11.8% (versus 9.8% for our study) which is mainly related to the complications of induced prematurity, Retroplacental Hematoma (HRP) and Intra-Uterine Growth Delay (IUGR) [6].

**CONCLUSION**

Eclampsia remains common in developing countries. It is still responsible for high maternal and child mortality. The association of two or more serious factors is especially important concerning the mortality. Improving the prognosis involves prevention with early and regular monitoring of pregnancy, and early management of pre-eclampsia and eclampsia before the presentation of clinical symptoms. Finally, a multidisciplinary approach, with a greater participation of anesthesiologists-resuscitators, and the creation of specialized fields in anesthesia-obstetrics and neonatal resuscitation are needed in developing countries.
