(Dated: March 22, 2022)
Abstract

Ensemble learning of $K$ nonlinear perceptrons, which determine their outputs by sign functions, is discussed within the framework of online learning and statistical mechanics. One purpose of statistical learning theory is to theoretically obtain the generalization error. This paper shows that ensemble generalization error can be calculated by using two order parameters, that is, the similarity between a teacher and a student, and the similarity among students. The differential equations that describe the dynamical behaviors of these order parameters are derived in the case of general learning rules. The concrete forms of these differential equations are derived analytically in the cases of three well-known rules: Hebbian learning, perceptron learning and AdaTron learning. Ensemble generalization errors of these three rules are calculated by using the results determined by solving their differential equations. As a result, these three rules show different characteristics in their affinity for ensemble learning, that is “maintaining variety among students.” Results show that AdaTron learning is superior to the other two rules with respect to that affinity.

I. INTRODUCTION

Ensemble learning has recently attracted the attention of many researchers [1, 2, 3, 4, 5, 6]. Ensemble learning means to combine many rules or learning machines (students in the following) that perform poorly. Theoretical studies analyzing the generalization performance by using statistical mechanics [7, 8] have been performed vigorously [4, 5, 6].

Hara and Okada [4] theoretically analyzed the case in which students are linear perceptrons. Their analysis was performed with statistical mechanics, focusing on the fact that the output of a new perceptron, whose connection weight is equivalent to the mean of those of students, is identical to the mean outputs of students. Krogh and Sollich [5] analyzed ensemble learning of linear perceptrons with noises within the framework of batch learning. They showed that the generalization performance can be optimized by choosing the best size of learning samples for a large $K$ limit, where $K$ is the number of students, and that the generalization performance can be improved by dividing learning samples in the noisy situation when $K$ is finite.

On the other hand, Hebbian learning, perceptron learning and AdaTron learning are well-known as learning rules for a nonlinear perceptron, which decides its output by sign function [9, 10, 11, 12]. Urbanczik [6] analyzed ensemble learning of nonlinear perceptrons that decide their outputs by sign functions for a large $K$ limit within the framework of online learning [13]. He treated a generalized learning rule that he termed a “soft version of perceptron learning,” which includes both Hebbian learning and perceptron learning as special cases, and discussed it from the viewpoint of generalization error. As a result, he showed that though an ensemble usually has superior performance to a single student, an ensemble has no special advantage in the optimized case within the framework of the soft version of perceptron learning. He considered a limit of ensemble learning.

Though Urbanczik discussed ensemble learning of nonlinear perceptrons within the framework of online learning, he treated only the case in which the number $K$ of students is large enough. Determining differences among ensemble learnings with Hebbian learning, perceptron learning and AdaTron learning (three typical learning rules), is a very attractive problem, but it is one that has never been analyzed to the best of our knowledge.

Based on the past studies, we discuss ensemble learning of $K$ nonlinear perceptrons, which decide their outputs by sign functions within the framework of online learning and
finite $K$ [14, 15]. First, we show that an ensemble generalization error of $K$ students can be calculated by using two order parameters: one is a similarity between a teacher and a student, the other is a similarity among students. Next, we derive differential equations that describe dynamical behaviors of these order parameters in the case of general learning rules. After that, we derive concrete differential equations about three well-known learning rules: Hebbian learning, perceptron learning and AdaTron learning. We calculate the ensemble generalization errors by using results obtained through solving these equations numerically.

Two methods are treated to decide an ensemble output. One is the majority vote of students, and the other is an output of a new perceptron whose connection weight equals the mean of those of students. As a result, we show that these three learning rules have different properties with respect to an affinity for ensemble learning, and AdaTron learning, which is known to have the best asymptotic property [9, 10, 11, 12], is the best among the three learning rules within the framework of ensemble learning.

II. MODEL

Each student treated in this paper is a perceptron that decides its output by a sign function. An ensemble of $K$ students is considered. Connection weights of students are $J_1, J_2, \ldots, J_K$. $J_k = (J_{k1}, \ldots, J_{kN}), k = 1, 2, \ldots, K$ and input $x = (x_1, \ldots, x_N)$ are $N$ dimensional vectors. Each component $x_i$ of $x$ is assumed to be an independent random variable that obeys the Gaussian distribution $\mathcal{N}(0, 1/N)$. Each component of $J_k^0$, that is the initial value of $J_k$, is assumed to be generated according to the Gaussian distribution $\mathcal{N}(0, 1)$ independently. Thus,

$$\langle x_i \rangle = 0, \quad \langle (x_i)^2 \rangle = \frac{1}{N},$$

$$\langle J_{ki}^0 \rangle = 0, \quad \langle (J_{ki}^0)^2 \rangle = 1,$$

where $\langle \cdot \rangle$ denotes the average. Each student’s output is $\text{sgn}(u_1l_1), \text{sgn}(u_2l_2), \ldots, \text{sgn}(u_Kl_K)$ where

$$\text{sgn}(ul) = \begin{cases} +1, & ul \geq 0, \\ -1, & ul < 0, \end{cases}$$

$$u_kl_k = J_k \cdot x.$$
Here, \( l_k \) denotes the length of student \( \mathbf{J}_k \). This is one of the order parameters treated in this paper and will be described in detail later. In this paper, \( u_k \) is called a normalized internal potential of a student.

The teacher is also perceptron that decides its output by a sign function. The teacher’s connection weight is \( \mathbf{B} \). In this paper, \( \mathbf{B} \) is assumed to be fixed where \( \mathbf{B} = (B_1, \cdots, B_N) \) is also an \( N \) dimensional vector. Each component \( B_i \) is assumed to be generated according to the Gaussian distribution \( \mathcal{N}(0, 1) \) independently. Thus,

\[
\langle B_i \rangle = 0, \quad \langle (B_i)^2 \rangle = 1.
\] (5)

The teacher’s output is \( \text{sgn}(v) \) where

\[
v = \mathbf{B} \cdot \mathbf{x}.
\] (6)

Here, \( v \) represents an internal potential of the teacher. For simplicity, the connection weight of a student and that of the teacher are simply called student and teacher, respectively.

In this paper the thermodynamic limit \( N \to \infty \) is also treated. Therefore,

\[
|\mathbf{x}| = 1, \quad |\mathbf{B}| = \sqrt{N}, \quad |\mathbf{J}_k^0| = \sqrt{N},
\] (7)

where \( |\cdot| \) denotes a vector norm. Generally, a norm of student \( |\mathbf{J}_k| \) changes as the time step proceeds. Therefore, the ratio \( l_k \) of the norm to \( \sqrt{N} \) is considered and is called a length of student \( \mathbf{J}_k \). That is,

\[
|\mathbf{J}_k| = l_k \sqrt{N},
\] (8)

where \( l_k \) is one of the order parameters treated in this paper.

The common input \( \mathbf{x} \) is presented to the teacher and all students in the same order. Each student compares its output and an output of the teacher for input \( \mathbf{x} \). Each student’s connection weight is corrected for the increasing probability that the student output agrees with that of the teacher. This procedure is called learning, and a method of learning is called learning rule, of which Hebbian learning, perceptron learning and AdaTron learning are well-known examples.[9, 10, 11, 12] Within the framework of online learning, information that can be used for correction other than that regarding a student itself is only input \( \mathbf{x} \) and an output of the teacher for that input. Therefore, the update can be expressed as follows,

\[
\mathbf{J}^{m+1}_k = \mathbf{J}^m_k + f_k^m \mathbf{x}^m,
\] (9)

\[
f_k^m = f(\text{sgn}(v^m), u_k^m),
\] (10)
where \( m \) denotes time step, and \( f \) is a function determined by learning rule.

In this paper, two methods are treated to determine an ensemble output. One is the majority vote of \( K \) students, which means an ensemble output is decided to be +1 if students whose outputs are +1 exceed the number of students whose outputs are −1, and −1 in the opposite case.

Another method for deciding an ensemble output is adopting an output of a new perceptron whose connection weight is the mean of the weights of \( K \) students. This method is simply called the weight mean in this paper.

### III. THEORY

In this paper, the majority vote and the weight mean are treated to determine an ensemble output. We use

\[
\epsilon = \Theta \left( -\text{sgn} (B \cdot x) \text{sgn} \left( \sum_{k=1}^{K} \text{sgn} (J_k \cdot x) \right) \right),
\]

and

\[
\epsilon = \Theta \left( -\text{sgn} (B \cdot x) \text{sgn} \left( \frac{1}{K} \sum_{k=1}^{K} J_k \cdot x \right) \right),
\]

as error \( \epsilon \) for the majority vote and the weight mean, respectively. Here, \( \epsilon \), \( x \) and \( J_k \) denote \( \epsilon^m \), \( x^m \) and \( J_k^m \), respectively. However, superscripts \( m \), which represent time steps, are omitted for simplicity. Then, \( \Theta(\cdot) \) is the step function defined as

\[
\Theta(z) = \begin{cases} 
+1, & z \geq 0, \\
0, & z < 0.
\end{cases}
\]

In both cases, \( \epsilon = 0 \) if an ensemble output agrees with that of the teacher and \( \epsilon = 1 \) otherwise. Generalization error \( \epsilon_g \) is defined as the average of error \( \epsilon \) over the probability distribution \( p(x) \) of input \( x \). The generalization error \( \epsilon_g \) can be regarded as the probability that an ensemble output disagrees with that of the teacher for a new input \( x \). One purpose of statistical learning theory is to theoretically obtain generalization error. In the case of a majority vote, using Eqs. (4), (6) and (11), we obtain

\[
\epsilon = \Theta \left( -\text{sgn}(v) \sum_{k=1}^{K} \text{sgn}(u_k) \right).
\]
In the case of a weight mean, using Eqs. (4), (6) and (12), we obtain
\[ \epsilon = \Theta \left( -\text{sgn} (v) \text{sgn} \left( \sum_{k=1}^{K} u_k \right) \right). \quad (15) \]

That is error \( \epsilon \) can be described as \( \epsilon = \epsilon(\{u_k\}, v) \) by using a normalized internal potential \( u_k \) for the student and an internal potential \( v \) for the teacher in both cases. Therefore, the generalization error \( \epsilon_g \) can be also described as
\[
\epsilon_g = \int \! dx p(x) \epsilon \\
= \int \prod_{k=1}^{K} du_k dv p(\{u_k\}, v) \epsilon(\{u_k\}, v), \quad (16)
\]
by using the probability distribution \( p(\{u_k\}, v) \) of \( u_k \) and \( v \). From Eq. (4), we can write
\[
u_k = \frac{1}{l_k} \sum_{i=1}^{N} J_{ki} x_i, \quad (17)
\]
where \( J_{ki} x_i, i = 1, \ldots, N \) are independent and identically distributed random variables. In the same manner, from Eq. (6), we can write
\[
v = \sum_{i=1}^{N} B_i x_i, \quad (18)
\]
where \( B_i x_i, i = 1, \ldots, N \) are independent and identically distributed random variables. Since the thermodynamic limit \( N \to \infty \) is also considered in this paper, \( u_k \) and \( v \) obey the multiple Gaussian distribution based on the central limit theorem. The discussion in this paper falls within the framework of online learning, which means input \( x \), once used for an update, is abandoned and \( x \) for each time step is generated according to the Gaussian distribution of Eq. (1). Therefore, since an input \( x \) and a student \( J_k \) have no correlation...
with each other, from Eq. (4), the mean and the variance of $u_k$ are

$$
\langle u_k \rangle = \left< \frac{1}{l_k} J_k \cdot x \right>
$$

(19)

$$
= \left< \frac{1}{l_k} \sum_{i=1}^{N} J_{ki} x_i \right>
$$

(20)

$$
= \frac{1}{l_k} \sum_{i=1}^{N} \langle J_{ki} \rangle \langle x_i \rangle
$$

(21)

$$
= 0,
$$

(22)

$$
\langle (u_k)^2 \rangle = \left< \left( \frac{1}{l_k} J_k \cdot x \right)^2 \right>
$$

(23)

$$
= \left< \frac{1}{l_k^2} \sum_{i=1}^{N} J_{ki} x_i \sum_{j=1}^{N} J_{kj} x_j \right>
$$

(24)

$$
= \frac{1}{l_k^2} \sum_{i=1}^{N} \langle (J_{ki})^2 \rangle \langle (x_i)^2 \rangle
$$

(25)

$$
= 1,
$$

(26)

respectively. In the same manner, since an input $x$ and a teacher $B$ have no correlation with each other, from Eq. (6), the mean and the variance of $v$ are

$$
\langle v \rangle = \langle B \cdot x \rangle
$$

(27)

$$
= \left< \sum_{i=1}^{N} B_i x_i \right>
$$

(28)

$$
= \sum_{i=1}^{N} \langle B_i \rangle \langle x_i \rangle
$$

(29)

$$
= 0,
$$

(30)

$$
\langle v^2 \rangle = \langle (B \cdot x)^2 \rangle
$$

(31)

$$
= \left< \sum_{i=1}^{N} B_i x_i \sum_{j=1}^{N} B_j x_j \right>
$$

(32)

$$
= \sum_{i=1}^{N} \langle (B_i)^2 \rangle \langle (x_i)^2 \rangle
$$

(33)

$$
= 1,
$$

(34)

respectively.

From these, all diagonal components of the covariance matrix $\Sigma$ of $p(\{u_k\}, v)$ equal unity.

Let us discuss a direction cosine between connection weights as preparation for obtaining non-diagonal components. First, $R_k$ is defined as a direction cosine between a teacher $B$
and a student $J_k$. That is,

$$R_k \equiv \frac{B \cdot J_k}{|B||J_k|} = \frac{1}{l_k N} \sum_{i=1}^{N} B_i J_{ki}. \quad (35)$$

When a teacher $B$ and a student $J_k$ have no correlation, $R_k = 0$, and $R_k = 1$ when the directions of $B$ and $J_k$ agree. Therefore, $R_k$ is called the similarity (overlap in other word) between teacher and student in the following. Furthermore, $R_k$ is the second order parameter treated in this paper. Next, $q_{kk'}$ is defined as a direction cosine between a student $J_k$ and another student $J_{k'}$. That is,

$$q_{kk'} \equiv \frac{J_k \cdot J_{k'}}{|J_k||J_{k'}|} = \frac{1}{l_k l_{k'} N} \sum_{i=1}^{N} J_{ki} J_{k'i}, \quad (36)$$

where $k \neq k'$. When a student $J_k$ and another student $J_{k'}$ have no correlation, $q_{kk'} = 0$, and $q_{kk'} = 1$ when the directions of $J_k$ and $J_{k'}$ agree. Therefore, $q_{kk'}$ is called the similarity among students in the following, and $q_{kk'}$ is the third order parameter treated in this paper.

Covariance between an internal potential $v$ of a teacher $B$ and a normalized internal potential $u_k$ of a student $J_k$ equals a similarity $R_k$ between a teacher $B$ and a student $J_k$ as follows,

$$\langle vu_k \rangle = \left\langle \frac{1}{l_k} \sum_{i=1}^{N} B_i x_i \sum_{j=1}^{N} J_{kj} x_j \right\rangle \quad (37)$$

$$= \frac{1}{l_k} \sum_{i=1}^{N} \langle B_i J_{ki} \rangle \langle (x_i)^2 \rangle \quad (38)$$

$$= \frac{1}{l_k N} \sum_{i=1}^{N} \langle B_i J_{ki} \rangle \quad (39)$$

$$= R_k. \quad (40)$$

Covariance between a normalized internal potential $u_k$ of a student $J_k$ and a normalized internal potential $u_{k'}$ of another student $J_{k'}$ equals a similarity $q_{kk'}$ among students as
follows,

\[
\langle u_k u_{k'} \rangle = \left\langle \frac{1}{l_k l_{k'}} \sum_{i=1}^{N} J_{ki} x_i \sum_{j=1}^{N} J_{k'j} x_j \right\rangle 
\]

(41)

\[
= \frac{1}{l_k l_{k'}} \sum_{i=1}^{N} \langle J_{ki} J_{k'i} \rangle \langle (x_i)^2 \rangle 
\]

(42)

\[
= \frac{1}{l_k l_{k'} N} \sum_{i=1}^{N} \langle J_{ki} J_{k'i} \rangle 
\]

(43)

\[
= q_{kk'}. 
\]

(44)

Therefore, Eq. (16) can be rewritten as

\[
\epsilon_g = \int \prod_{k=1}^{K} du_k dv \epsilon(\{u_k\}, v), 
\]

(45)

\[
p(\{u_k\}, v) = \frac{1}{(2\pi)^{K+1}|\Sigma|^\frac{1}{2}} 
\]

\[
\times \exp \left( -\frac{\left(\{u_k\}, v\right) \Sigma^{-1} \left(\{u_k\}, v\right)^T}{2} \right), 
\]

(46)

\[
\Sigma = \begin{pmatrix}
1 & q_{12} & \ldots & q_{1K} & R_1 \\
q_{21} & 1 & \ddots & \vdots & \vdots \\
\vdots & \ddots & \ddots & q_{K-1,K} & \vdots \\
q_{k1} & \ldots & q_{K,K-1} & 1 & R_K \\
R_1 & \ldots & \ldots & R_K & 1 \\
\end{pmatrix}
\]

(47)

As a result, a generalization error \(\epsilon_g\) can be calculated if all similarities \(R_k\) and \(q_{kk'}\) are obtained. Let us thus discuss differential equations that describe dynamical behaviors of these order parameters. In this paper, norms of inputs, teacher and students are set as Eq. (7): influence of input can be replaced with the average over the distribution of inputs (sample average) in a large \(N\) limit. This idea is called self-averaging in statistical mechanics. Differential equations regarding \(l_k\) and \(R_k\) for general learning rules have been obtained based on self-averaging as follows[9],

\[
\frac{dl_k}{dt} = \langle f_k u_k \rangle + \frac{\langle f_k^2 \rangle}{2l_k}, 
\]

(48)

\[
\frac{dR_k}{dt} = \langle f_k v \rangle - \langle f_k u_k \rangle R_k - \frac{R_k}{2l_k^2} \langle f_k^2 \rangle, 
\]

(49)
where \( \langle \cdot \rangle \) stands for the sample average. That is,

\[
\langle f_k u_k \rangle = \int du_k dv p_2(u_k, v) f(\text{sgn}(v), u_k) u_k,
\]

\( (50) \)

\[
\langle f_k v \rangle = \int du_k dv p_2(u_k, v) f(\text{sgn}(v), u_k) v,
\]

\( (51) \)

\[
\langle f_k^2 \rangle = \int dv p_2(u_k, v) (f(\text{sgn}(v), u_k))^2,
\]

\( (52) \)

\[
p_2(u_k, v) = \frac{1}{2\pi|\Sigma_2|^\frac{1}{2}} \times \exp \left( -\frac{(u_k, v)\Sigma_2^{-1}(u_k, v)^T}{2} \right),
\]

\( (53) \)

\[
\Sigma_2 = \begin{pmatrix} 1 & R_k \\ R_k & 1 \end{pmatrix}.
\]

\( (54) \)

Next, let us derive a differential equation regarding \( q_{kk'} \) for the general learning rule. Considering a student \( J_k \) and another student \( J_{k'} \) and rewriting as \( l_k^m \rightarrow l_k, l_k^{m+1} \rightarrow l_k + dl_k \),

\( q_{kk}^m \rightarrow q_{kk'}, q_{kk}^{m+1} \rightarrow q_{kk'} + dq_{kk'} \) and \( 1/N \rightarrow dt \), a differential equation regarding \( q \) is obtained as follows [4],

\[
\frac{dq_{kk'}}{dt} = \frac{\langle f_{k'} u_k \rangle - q_{kk'} \langle f_{k'} u_{k'} \rangle}{l_{k'}}
+ \frac{\langle f_k u_{k'} \rangle - q_{kk'} \langle f_k u_k \rangle}{l_k}
+ \frac{\langle f_k f_{k'} \rangle}{l_k l_{k'}} - \frac{q_{kk'}}{2} \left( \frac{\langle f_k^2 \rangle}{l_k^2} + \frac{\langle f_{k'}^2 \rangle}{l_{k'}^2} \right),
\]

\( (55) \)
from Eqs. (9), (36), (48) and self-averaging, where

\[
\langle f_k u_{k'} \rangle = \int du_k du_{k'} dv p_3(u_k, u_{k'}, v) \\
\times f(\text{sgn}(v), u_k) u_{k'}, \\
\langle f_{k'} u_k \rangle = \int du_k du_{k'} dv p_3(u_k, u_{k'}, v) \\
\times f(\text{sgn}(v), u_{k'}) u_k, \\
\langle f_k f_{k'} \rangle = \int du_k du_{k'} dv p_3(u_k, u_{k'}, v) \\
\times f(\text{sgn}(v), u_k) f(\text{sgn}(v), u_{k'}),
\]

\[
\langle f_k u_{k'} \rangle = \langle f_{k'} u_k \rangle, \\
\langle f_k f_{k'} \rangle = \langle f_{k'} f_k \rangle
\]

\[
p_3(u_k, u_{k'}, v) = \frac{1}{(2\pi)^{\frac{3}{2}} |\Sigma_3|^{\frac{3}{2}}} \\
\times \exp \left( -\frac{(u_k, u_{k'}, v) \Sigma_3^{-1}(u_k, u_{k'}, v)^T}{2} \right),
\]

\[
\Sigma_3 = \begin{pmatrix}
1 & q_{k'k} & R_k \\
q_{k'k} & 1 & R_{k'} \\
R_k & R_{k'} & 1
\end{pmatrix}
\]

IV. RESULT

A. Conditions of analytical calculations

As described above, in this paper each component of initial value \( J_0^k \) of student \( J_k \) and teacher \( B \) is generated independently according to the Gaussian distribution \( \mathcal{N}(0, 1) \), and the thermodynamic limit \( N \to \infty \) is considered. Therefore, all \( J_0^k \) and \( B \) are orthogonal to each other. That is,

\[
R_k^0 = 0, \quad q_{k'k}^0 = 0.
\]

From Eq. (61) and symmetry of students, we can write

\[
\langle f_k u_{k'} \rangle = \langle f_{k'} u_k \rangle, \quad \langle f_k f_{k'} \rangle = \langle f_{k'} f_k \rangle
\]

in Eq. (56). From Eq. (61) and symmetry among students, we omit subscripts \( k, k' \) from order parameters \( l_k, R_k \) and \( q_{k'k} \) in Eqs. (48)–(60) and write them as \( l, R \) and \( q \). In the following sections, we analytically obtain five sample averages \( \langle f_k u_k \rangle, \langle f_k v \rangle, \langle f_k^2 \rangle, \langle f_k u_{k'} \rangle \) and \( \langle f_k f_{k'} \rangle \) concretely, which are necessary to solve Eqs. (48)–(60) with respect to typical
learning rules under the conditions given in Eqs. (51)–(52). $R$ and $q$ are obtained by solving the above sample averages and Eqs. (48)–(49) and (55) and (51) numerically. We obtain numerical ensemble generalization errors $\epsilon_g$ by solving Eq. (45) with the obtained $R$ and $q$.

### B. Hebbian learning

The update procedure for Hebbian learning is

$$f(\text{sgn}(v), u) = \text{sgn}(v).$$

(63)

Using this expression, $\langle f_k u_k \rangle$, $\langle f_k v \rangle$ and $\langle f_k^2 \rangle$ in the case of Hebbian learning can be obtained as follows by executing Eqs. (50)–(52) analytically.

$$\langle f_k u_k \rangle = \frac{2R}{\sqrt{2\pi}}, \quad \langle f_k v \rangle = \sqrt{\frac{2}{\pi}}, \quad \langle f_k^2 \rangle = 1.$$  

(64)

In this section, $\langle f_k u_k' \rangle$ and $\langle f_k f_k' \rangle$ are derived. Since Eq. (63) is independent of $u$, we obtain

$$\langle f_k u_k' \rangle = \langle f_k u_k \rangle = \frac{2R}{\sqrt{2\pi}},$$

(65)

$$\langle f_k f_k' \rangle = \langle (\text{sgn}(v))^2 \rangle = 1.$$  

(66)

$R$ and $q$ have been obtained by solving Eqs. (48), (49), (55), (62), (61)–(66) numerically. We have obtained numerical ensemble generalization errors $\epsilon_g$ in the case of $K = 3$ by using Eqs. (45)–(47) and the above $R$ and $q$. Figure 1 shows the results. In this figure, MV and WM indicate the majority vote and the weight mean, respectively. Numerical integrations of Eq. (45) in theoretical calculations have been executed by using the six-point closed Newton-Cotes formula. In the computer simulation, $N = 10^4$ and ensemble generalization errors have been obtained through tests using $10^5$ random inputs at each time step. In this figure, the result of theoretical calculations of $K = 1$ is also shown to clarify the effect of the ensemble. This figure shows that the ensemble generalization errors obtained by theoretical calculation explain the computer simulation quantitatively.

Figures 2–3 show the results of computer simulations where $N = 10^3$, $K = 1, 3, 11, 31$ until $t = 10^4$ in order to investigate asymptotic behaviors of generalization errors. Asymptotic behavior of generalization error in Hebbian learning in the case of the number $K$ of students at unity is $O(t^{-\frac{1}{2}})$. Asymptotic orders of the generalization error in the case of ensemble
FIG. 1: Dynamical behaviors of ensemble generalization error $\epsilon_g$ in Hebbian learning.

learning are considered equal to those of $K = 1$, since properties of $K = 3, 11, 31$ are parallel to those of $K = 1$ in these figures.

FIG. 2: Asymptotic behavior of generalization error of majority vote in Hebbian learning. Computer simulations, except for the solid line. Asymptotic order of ensemble learning is the same as that at $K = 1$.

To clarify the relationship between $K$ and the effect of ensemble, we have obtained theoretical ensemble generalization errors for various values of $K$. Here, it is difficult to execute numerical integration of Eq. (45) when $K > 3$ by the Newton-Cotes formula used in the calculations for Figure 1. Therefore, the Metropolis method, which is a type of MonteCarlo method, has been used. We then orthogonalized the variables of integration to
FIG. 3: Asymptotic behavior of generalization error of weight mean in Hebbian learning. Computer simulations, except for the solid line. Asymptotic order of ensemble learning is the same as that at $K = 1$.

eliminate the calculation of inverse matrices of Eq. (67). That is,

$$u_k = a\bar{u}_k + b\hat{u} + cv, \quad k = 1, 2, \ldots, K,$$

where $u_k, \bar{u}_k, \hat{u}$ and $v$ obey the Gaussian distribution $\mathcal{N}(0, 1)$ and $\bar{u}_k, \hat{u}$ and $v$ have no correlation with each other. Considering that subscripts $k, k'$ have been omitted from order parameters $R_k, q_{kk'}$ and Eq. (67), conditions that $a, b$ and $c$ must satisfy are

$$a^2 + b^2 + c^2 = 1,$$

$$b^2 + c^2 = q,$$

$$c = R.$$  \hspace{1cm} (68, 69, 70)

Therefore,

$$a = \sqrt{1 - q},$$

$$b = \sqrt{q - R^2},$$

$$c = R.$$  \hspace{1cm} (71, 72, 73)

By using these $a, b$ and $c$, we can rewrite Eqs. (67) as follows:

$$\epsilon_g = \int K \prod_{k=1}^{K} d\bar{u}_k p_1(\bar{u}_k) d\hat{u} p_1(\hat{u}) dvp_1(v) \epsilon(a\bar{u}_k + b\hat{u} + cv),$$

$$p_1(u) = \frac{1}{(2\pi)^{\frac{1}{2}}} \exp \left( -\frac{u^2}{2} \right).$$  \hspace{1cm} (74, 75)
These operations orthogonalized the variables of integration in exchange for their number having been increased from $K + 1$ to $K + 2$. The multiple Gaussian distribution function $p(\{u_k\}, v)$ can be rewritten as products of simple Gaussian distribution functions $p_1(\cdot)$ by this orthogonalization. Thus, calculations of inverse matrices of Eq. (17) become unnecessary.

These facts have made it easy to perform the numerical calculations of the generalization error for a large $K$.

Figure 4 shows the results obtained by the Metropolis method using the values of $R$ and $q$ calculated numerically for Hebbian learning and Eqs. (71)–(75). Calculations have been executed for $K = 1, 3, 5, 7, 9, 11, 13, 21, 31$ and $51$ in both the majority vote (MV) and the weight mean (WM). The number of MonteCarlo steps is $10^9$. These theoretical results are fitted to two quadratic curves. In this figure, the results of computer simulations where $N = 10^4CK = 1, 3, 5, 7, 9, 11, 13, 21, 31$ and $51$ have also been drawn for comparison with the theoretical calculations. In the computer simulations, ensemble generalization errors have been obtained through tests using $10^6$ random inputs. The figures show the values of $t = 50$ for both theoretical calculations and computer simulations, and this is the time for which is considered that the learnings are sufficiently within the asymptotic regions with respect to Figures 2–3. Here, since the relationship between $1/K$ and ensemble generalization errors shows a straight line in the case of linear perceptrons, the abscissa is $1/K$ in Figure 4. The ordinates have been normalized by the theoretical ensemble generalization error of $K = 1$ and $t = 50$.

![Figure 4](image_url)

**FIG. 4:** Relationship between $K$ and effect of ensemble in Hebbian learning. Ensemble generalization error $\epsilon_g$ for a large $K$ limit is about 0.99 times that of $K = 1$. 
C. Perceptron learning

The update procedure for perceptron learning is

\[ f(\text{sgn}(v), u) = \Theta(-uv)\text{sgn}(v). \] (76)

Using this expression, \( \langle f_k u_k \rangle \), \( \langle f_k v \rangle \) and \( \langle f_k^2 \rangle \) in the case of perceptron learning can be obtained as follows by executing Eqs. (50)–(52) analytically [9, 16].

\[ \langle f_k u_k \rangle = R - \frac{1}{\sqrt{2\pi}}, \quad \langle f_k v \rangle = \frac{1 - R}{\sqrt{2\pi}}, \] (77)

\[ \langle f_k^2 \rangle = 2 \int_0^\infty DvH\left(\frac{Rv}{\sqrt{1-R^2}}\right) = \frac{1}{\pi} \tan^{-1}\frac{\sqrt{1-R^2}}{R}. \] (78)

In this section, \( \langle f_k u_{k'} \rangle \) and \( \langle f_k f_{k'} \rangle \) are derived. Using Eq. (76), \( \langle f_k u_{k'} \rangle \) and \( \langle f_k f_{k'} \rangle \) in the case of perceptron learning are obtained as follows by executing Eqs. (56) and (58) analytically.

\[ \langle f_k u_{k'} \rangle = \int du_k du_{k'} dv_3 (u_k, u_{k'}, v) \times \Theta(-u_k v)\text{sgn}(v)u_{k'} = R - q \sqrt{2\pi} \] (79)

\[ \langle f_k f_{k'} \rangle = \int du_k u_{k'} dv_3 (u_k, u_{k'}, v) \times \Theta(-u_k v)\Theta(-u_{k'} v) = 2 \int_0^\infty Dv \int_{\frac{Rq}{\sqrt{1-R^2}}}^\infty Dx H(z) \] (80)

where

\[ z \equiv \frac{-(q - R^2)x + R\sqrt{1-R^2}v}{\sqrt{(1-q)(1+q-2R^2)}} \] (81)

and the definitions of \( H(u) \) and \( Dx \) are

\[ H(u) \equiv \int_u^\infty Dx \] (82)

\[ Dx \equiv \frac{dx}{\sqrt{2\pi}} \exp\left(-\frac{x^2}{2}\right). \] (83)

In the same manner as Hebbian learning, \( R \) and \( q \) have been obtained by solving Eqs. (48), (49), (55), (61), (62), (77)–(80) numerically. We have obtained numerical ensemble
generalization errors $\epsilon_g$ in the case of $K = 3$ by using Eqs. (45)–(47) and the above $R$ and $q$. Figure 5 shows the results. This figure shows that the ensemble generalization errors obtained by theoretical calculation explain the computer simulation quantitatively.

\[ \text{FIG. 5: Dynamical behaviors of ensemble generalization error } \epsilon_g \text{ in perceptron learning.} \]

Figures 6–7 show the results of computer simulations where $N = 10^3, K = 1, 3, 11, 31$ until $t = 10^4$ in order to investigate asymptotic behaviors of generalization errors. Effect of ensemble is maintained asymptotically. Asymptotic behavior of generalization error in perceptron learning in the case of the number $K$ of students at unity is $O(t^{-\frac{1}{3}})$. Asymptotic orders of the generalization error in the case of ensemble learning are considered equal to those of $K = 1$, since properties of $K = 3, 11, 31$ are parallel to those of $K = 1$ in these figures.

To clarify the relationship between $K$ and the effect of ensemble, we have obtained theoretical ensemble generalization errors for various values of $K$. In the same manner as Hebbian learning, Figure 8 shows the results obtained by the Metropolis method using the values of $R$ and $q$ calculated numerically for perceptron learning and Eqs. (71)–(75).

**D. AdaTron learning**

The update procedure for AdaTron learning is

\[ f(\text{sgn}(v), u) = -u \Theta (-uv) . \] (84)
FIG. 6: Asymptotic behavior of generalization error of majority vote in perceptron learning. Computer simulations, except for the solid line. Asymptotic order of ensemble learning is the same as that at $K = 1$.

FIG. 7: Asymptotic behavior of generalization error of weight mean in perceptron learning. Computer simulations, except for the solid line. Asymptotic order of ensemble learning is the same as that at $K = 1$.

Using this expression, $\langle f_k u_k \rangle$, $\langle f_k v \rangle$ and $\langle f_k^2 \rangle$ in the case of AdaTron learning can be
FIG. 8: Relationship between \( K \) and effect of ensemble in perceptron learning. Ensemble generalization error \( \epsilon_g \) for a large \( K \) limit is about 0.72 times that of \( K = 1 \).

obtained as follows by executing Eqs. (50)–(52) analytically.

\[
\langle f_k u_k \rangle = -2 \int_0^\infty D u u^2 H \left( \frac{R u}{\sqrt{1 - R^2}} \right) \quad (85)
\]

\[
= -\frac{1}{\pi} \cot^{-1} \left( \frac{R}{\sqrt{1 - R^2}} \right) + \frac{1}{\pi} R \sqrt{1 - R^2} \quad (86)
\]

\[
\langle f_k v \rangle = \frac{(1 - R^2)^{3/2}}{\pi} + R \langle f_k u_k \rangle \quad (87)
\]

\[
\langle f_k^2 \rangle = -\langle f_k u_k \rangle \quad (88)
\]

In this section, \( \langle f_k u_k' \rangle \) and \( \langle f_k f_k' \rangle \) are derived. Using Eq. (84), \( \langle f_k u_k' \rangle \) and \( \langle f_k f_k' \rangle \) in the case of AdaTron learning are obtained as follows by executing Eqs. (56) and (58) analytically.
\[ \langle f_k u_{k'} \rangle = - \int du_k du_{k'} dv p_3(u_k, u_{k'}, v) \Theta(-u_k v) u_k u_{k'} \]
\[ = \frac{1+q}{\pi} R \sqrt{1-R^2} - 2q \int_0^\infty Dv \int_{Rv/\sqrt{1-R^2}}^\infty Dxx^2 \]  
(89)

\[ \langle f_k f' \rangle = \int dv du_k du_{k'} u_k u_{k'} p_3(u_k, u_{k'}, v), \Theta(-u_k v) \Theta(-u_{k'} v) \]
\[ = \frac{(1-q)^2 (1+q-2R^2)}{2\pi (1-R^2)^2} \left( \sqrt{\frac{(1+q)(1-R^2)}{1-q}} - R \right) + 2(q-R^2) \int_0^\infty Dv \int_{Rv/\sqrt{1-R^2}}^\infty Dxx^2 H(z) \]
\[ - \frac{2R(1+q-R^2)}{\sqrt{1-R^2}} \int_0^\infty Duv \int_{Rv/\sqrt{1-R^2}}^\infty DxH(z) + 2R^2 \int_0^\infty Duv^2 \int_{Rv/\sqrt{1-R^2}}^\infty DxH(z), \]  
(90)

where the definitions of \( z \), \( H(u) \) and \( D_x \) are Eqs. (81), (82) and (83), respectively.

In the same manner as Hebbian learning, \( R \) and \( q \) have been obtained by solving Eqs. (48), (49), (55), (61), (62), (86)–(90) numerically. We have obtained numerical ensemble generalization errors \( \epsilon_g \) in the case of \( K = 3 \) by using Eqs. (45)–(47) and the above \( R \) and \( q \). Figure 9 shows the results. This figure shows that the ensemble generalization errors obtained by theoretical calculation explain the computer simulation quantitatively.

![Figure 9](image.png)

**FIG. 9:** Dynamical behaviors of ensemble generalization error \( \epsilon_g \) in AdaTron learning. Improvement of \( \epsilon_g \) by increasing \( K \) from 1 to 3 is largest of the three learning rules.

Figures 10–11 show the results of computer simulations where \( N = 10^3, K = 1, 3, 11, 31 \) until \( t = 10^4 \) in order to investigate asymptotic behaviors of generalization errors. Effect of ensemble is maintained asymptotically. Asymptotic behavior of generalization error in AdaTron learning in the case of the number \( K \) of students at unity is \( O(t^{-1}) \). Asymptotic
orders of the generalization error in the case of ensemble learning are considered equal to those of $K = 1$, since properties of $K = 3, 11, 31$ are parallel to those of $K = 1$ in these figures.

![Graph](image.png)

**FIG. 10:** Asymptotic behavior of generalization error of majority vote in AdaTron learning. Computer simulations, except for the solid line. Asymptotic order of ensemble learning is the same as that at $K = 1$.

![Graph](image.png)

**FIG. 11:** Asymptotic behavior of generalization error of weight mean in AdaTron learning. Computer simulations, except for the solid line. Asymptotic order of ensemble learning is the same as that at $K = 1$.

To clarify the relationship between $K$ and the effect of ensemble, we have obtained theoretical ensemble generalization errors for various values of $K$. In the same manner as
Hebbian learning, Figure 12 shows the results obtained by the Metropolis method using the values of $R$ and $q$ calculated numerically for perceptron learning and Eqs. (71)–(75).

FIG. 12: Relationship between $K$ and effect of ensemble in AdaTron learning. Ensemble generalization error $\epsilon_g$ for a large $K$ limit is about 0.68 times that of $K = 1$.

V. DISCUSSION

Figures 1C4C5C 8C9 and 12 show that the generalization errors of the three learning rules are all improved by ensemble learning. However, the degree of improvement is small in Hebbian learning and large in AdaTron learning. First, we discuss the reason for this difference in the following.

Each student moves towards teacher as learning proceeds. Therefore, similarities $R_k$ and $q_{kk'}$ increase and approach unity, leading to $R_k$ and $q_{kk'}$ becoming less irrelevant to each other. For example when $R_k = R_k' = 1$, $q_{kk'}$ cannot be $\neq 1$ since a teacher $B$, a student $J_k$ and another student $J_{k'}$ have the same direction. Thus, $R_k$ and $q_{kk'}$ are under a certain restraint relationship each other. When $q_{kk'}$ is relatively smaller when compared with $R_k$, variety among students is further maintained and the effect of the ensemble can be considered as large. On the contrary, after $q_{kk'}$ becomes unity, a student $J_k$ and another student $J_{k'}$ are the same and there is no merit in combining them.

Let us explain these considerations intuitively by using Figure 13. Both (a) and (b) show the relationship among two students $J_1$, $J_2$ and a teacher $B$ when learning has proceeded to some degree from the condition that the students and the teacher have no correlation.
Then, as shown in Figure 13, students must distribute to points the same distance from the teacher. That is, the similarity $R_1$ of the teacher and a student $J_1$ equals the similarity $R_2$ of the teacher and a student $J_2$ in both (a) and (b). Here, (a) shows the case in which students are unlike each other — in other words the variety among students is large, that is, $q$ is small. In this case, it is obvious that a mean vector of $J_1$ and $J_2$ is closer to the teacher $B$ than either $J_1$ or $J_2$. Therefore, a mean vector $\frac{1}{K} \sum_{k=1}^{K} J_k$ of the students’ connection weights can closely approximate the connection weight vector $B$ of the teacher in cases like (a). In addition, a combination method other than a mean of students, e.g. the majority vote of students, must approximate the teacher better than each student can do alone in cases like (a). In this case, the effect of ensemble learning is strong. On the contrary, Figure 13(b) shows the case in which students are similar to each other — in other words, the variety among students is small, meaning $q$ is large. In this case, the significance of combining two students is small since their outputs are almost always the same. Therefore, effect of ensemble learning is small when $q$ is large, as in Figure 13(b). Thus, the relationship between $R_k$ and $q_{kk'}$ is essential to know in ensemble learning.

![FIG. 13: Variety among students.](image)

Figure 14 shows a comparison between the theoretical results regarding the dynamical behaviors of $R$ and $q$ of Hebbian learning, which are obtained by solving Eqs. (48), (49), (55), (61), (62), (64)–(66) numerically and by computer simulation ($N = 10^5$). In the same manner, Figure 15 shows a comparison between the theoretical results regarding the dynamical behaviors of $R$ and $q$ of perceptron learning, which are obtained by solving Eqs. (48), (49), (55), (61), (62), (77)–(80) numerically and by computer simulation ($N = 10^5$). Figure 16 shows a comparison between the theoretical results regarding the dynamical
behaviors of \( R \) and \( q \) of AdaTron learning, which are obtained by solving Eqs. (48), (49), (55), (61), (62), (86)–(90) numerically and by computer simulation \((N = 10^5)\). In these figures, the theoretical results and the computer simulations closely agree with each other. That is, the derived theory explains the computer simulation quantitatively. Figure 14 shows that \( q \) rises more rapidly than \( R \) in Hebbian learning; in other words, \( q \) is relatively large when compared with \( R \), meaning the variety among students disappears rapidly in Hebbian learning. Figure 15 shows that \( q \) is smaller than \( R \) in the early period of learning \((t < 4.0)\), which means perceptron learning maintains the variety among students for a longer time than Hebbian learning. Figure 16 shows that \( q \) is relatively smaller when compared with \( R \) than in the cases of Hebbian learning and perceptron learning. This means AdaTron learning maintains variety among students most out of these three learning rules.

![Graph showing dynamical behaviors of R and q in Hebbian learning](image)

FIG. 14: Dynamical behaviors of \( R \) and \( q \) in Hebbian learning. Here, \( q \) rises more rapidly than \( R \), which means the variety among students disappears rapidly in Hebbian learning.

Figures 14–16 show that \( q \) is relatively small when compared with \( R \) in the case of AdaTron learning than in Hebbian learning and perceptron learning. As described before, the relationship between \( R \) and \( q \) is essential in ensemble learning. To illustrate this, Figure 17 shows the relationship more clearly by taking \( R \) and \( q \) as axes. In this figure, the curve for AdaTron learning is located in the bottom. That is, of the three learning rules, the one offering the smallest \( q \) when compared with \( R \) is AdaTron learning. In other words, the learning rule in which the rising of \( q \) is the slowest and the variety among students is maintained best is AdaTron learning.
FIG. 15: Dynamical behaviors of $R$ and $q$ in perceptron learning. Here, $q$ is smaller than $R$ in the early period of learning ($t < 4.0$). Perceptron learning maintains the variety among students for a longer time than Hebbian learning.

FIG. 16: Dynamical behaviors of $R$ and $q$ in AdaTron learning. Here, $q$ is relatively smaller when compared with $R$ than in the cases of Hebbian learning or perceptron learning. AdaTron learning maintains variety among students most out of these three learning rules.

These characteristics can be understood from the update expression of each rule. Equation 63 means that an update by Hebbian learning depends on only the output $\text{sgn}(v)$ of a teacher. That is, all students are updated identically at all time steps. Therefore, the similarity of students increases rapidly in Hebbian learning. On the other hand, the update by perceptron learning equals that of Hebbian learning times $\Theta(-uv)$, as shown in Eq. 76. Students whose outputs are opposite to that of a teacher change their connection
weights. At least in the initial period of learning, students whose output is opposite to that of a teacher and students whose output is the same as that of a teacher both exist. As a result, students that change their connection weights and students who don’t change their connection weights both exist, leading to the fact that variety among students by perceptron learning is better maintained than by Hebbian learning. The update by AdaTron learning is given in Eq. (84). This can be rewritten as \( f(\text{sgn}(v), u) = |u|\Theta(-uv)\text{sgn}(v) \). That is, the update by AdaTron learning equals that of perceptron learning times \(|u|\), which depends on the students. Therefore, the variety among students by AdaTron learning is still better maintained.

FIG. 17: Relationship between \( R \) and \( q \) (Theory). Here, \( q \) of AdaTron learning is the smallest when compared with \( R \). The rising of \( q \) is the slowest and variety among students is best maintained in AdaTron learning.

In the discussion above, the reason why the degree of improvement by ensemble learning is small in Hebbian learning and large in AdaTron learning as shown in Figures 1, 4, 5, 8, 9 and 12 have been explained. AdaTron learning originally featured the fastest asymptotic characteristic of the three learning rules[^9]. However, it has disadvantage that the learning is slow at the beginning; that is, the generalization error is larger than for the other two learning rules in the period of \( t < 6 \). This paper shows that the fastest asymptotic characteristic of AdaTron learning is maintained in ensemble learning and that AdaTron learning has a good affinity with ensemble learning in regard to “the variety among students” and the disadvantage of the early period can be improved by combining it with ensemble learning.
From the perspective of the difference between the majority vote and the weight mean, Figures 1, 4, 5, 8, 9 and 12 show that the improvement by weight mean is larger than that by majority vote in all three learning rules. Improvement in the generalization error by averaging connection weights of various students can be understood intuitively because the mean of students is close to that of the teacher in Figure 13(a). The reason why the improvement in the majority vote is smaller than that in the weight mean is considered to be that the variety among students cannot be utilized as effectively by the majority vote as by the weight mean. However, the majority vote can determine an ensemble output only using outputs of students, and is easy to implement. It is, therefore, significant that the effect of an ensemble in the case of the majority vote has been analyzed quantitatively.

Figures 4, 8 and 12 also show that the ensemble generalization errors $\epsilon_g$ by the majority vote are larger than those by the weight mean in the case of $K < \infty$. In both perceptron learning and AdaTron learning, the relationship between $1/K$ and $\epsilon_g$ shows a straight line and an upwards-convex curve in the case of the weight mean and the majority vote, respectively. The ensemble generalization errors $\epsilon_g$ in the cases of the majority vote and the weight mean agree with each other at a large $K$ limit. This fact agrees with the description in [6]. Therefore, the weight mean is superior than the majority vote especially in the case of a small $K$. Moreover, it is shown that $\epsilon_g$ for a large $K$ limit compared with that of $K = 1$ is about 0.99, 0.72 and 0.68 times in Hebbian, perceptron and AdaTron learning, respectively. It has been confirmed that ensemble has the strongest effect in AdaTron learning among three learning rules.

VI. CONCLUSION

This paper discussed ensemble learning of $K$ nonlinear perceptrons, which determine their outputs by sign functions within the framework of online learning and statistical mechanics. One purpose of statistical learning theory is to theoretically obtain the generalization error. In this paper, we have shown that the ensemble generalization error can be calculated by using two order parameters, that is the similarity between the teacher and a student, and the similarity among students. The differential equations that describe the dynamical behaviors of these order parameters have been derived in the case of general learning rules. The concrete forms of these differential equations have been derived analytically in the cases
of three well-known rules: Hebbian learning, perceptron learning and AdaTron learning. We calculated the ensemble generalization errors of these three rules by using the results determined by solving their differential equations. As a result, these three rules have different characteristics in their affinity for ensemble learning, that is, “maintaining variety among students.” The results show that AdaTron learning is superior to the other two rules with respect to that affinity.
