Abstract

Education acts as a soul in the overall societal development, in one way or the other. Aspirants, who gain their degrees genuinely, will help society with their knowledge and skills. But the other side of the coin, the problem of fake certificates, is alarming and worrying. It has been prevalent in different forms from paper-based dummy certificates to replicas backed with database tampering and has increased to astronomic levels in this digital era. In this regard, an overlay mechanism using Blockchain technology is proposed to store the genuine certificates in digital form and verify them firmly whenever needed without delay. The proposed system makes sure that the certificates, once verified, can be present online in an immutable form for further reference and provides a tamper-proof concealment to the existing certification system. To confirm the credibility of the proposed method, a prototype of blockchain-based credential securing and verification system is developed in ethereum test network. The implementation and test results show that it is a secure and feasible solution to online credential management system.

1. Introduction

As technology is advancing, the creation of fake certificates becomes easier. The forged certificates range from fake universities issuing certificates to forged certificates of existing reputed universities. This problem is being a pain in the neck for both the universities and recruiting organizations. According to CareerBuilder, a company can lose seventeen thousand dollars on average, for a wrong hire or for hiring someone with a fake qualification. The loss is not just financial but may also cost the lives of innocent people because of the constructions designed by fake engineers and treatment given by fake doctors. Validating the certificates properly before taking someone into an organization is the key to solve this hitch. The primary cause of this problem is that credential verification is not as easy as it is seen. It takes a lot of resources, time and money as well.

Blockchain technology helps us in building a decentralized application that keeps all the data secure and tamper-free. In this application, the data is stored in text format to ease the implementation and testing, but once the transaction is done the data is converted into hash values and stored in the block within the entire network. This provides security since a single bit of modification in a block should tamper all the data in the entire chain which is not possible because multiple copies are distributed in the peer network. So the Integrity of the data is maintained. The proposed method is implemented and tested using ethereum test net. Whenever some data is about to be stored in the block of an ethereum blockchain, some gas value is reduced from the admin account and distributed in the network and it acts as the reward for the miners whose system acts as the data carrier of the block. This gas is filled by spending some ether from their accounts. The etherium network limits gas availability in order to control infinite loops in the coding.

2. Related Work:
Research has been in progress to identify the fake documents and certificates, both paper and digital form. The following are some of the methods proposed to curtail fake documents. MV Ramana Murthy [1], presented a method to detect fake paper-based documents with ECC based digital signatures and cryptography. Xiaojing Gu [2], designed an attribute dependency-based detection method, called SSLight, in which some attribute dependencies are observed that are rarely present in legitimate samples. Dr. A. M. Kahonge [3], proposed a mechanism that uses the web and database programming, XML data sharing along with message passing via a very simple web service to share academic records between employers and the educational institutions. Zheng Dong [4], presented a scheme for detecting forged certificates from trusted CAs developed from a large and timely collection of certificates. In this method, classification is done automatically by building machine-learning models using Deep Neural Networks (DNN). Kajal P. Chavan [5], proposed a system where the digital data, which is encrypted in the marks memo as a QR code and can only be retrieved back and decrypted by authorized users only using their web-application, which is hosted in their website. But all these are centralized applications and can be easily tampered. The following are various applications proposed based on blockchain technology. Ming L [6], proposed a blockchain-based decentralized framework for crowdsourcing named CrowdBC, in which a requester's task can be solved by a group of workers without depending on any intermediate third party, users’ privacy can be guaranteed and also the required transaction fee is low. Haibo Yi [7], proposed an e-voting scheme, which is a blockchain-based and meets the essential requirements of the e-voting procedure. All votes are linked using hash values in a blockchain. Yi Chen [8], designed a storage scheme to store and manage personal medical data using blockchain and cloud storage. Ali Dorr [9], proposed a blockchain-based framework to protect the privacy of users and to improve the security of the vehicular ecosystem. Xiao Yue [10], proposed an application, healthcare data gateway, whose architecture is based on blockchain to enable patient to control and share their medical reports seamlessly and securely without violating the privacy, which also provides a new way to improve the efficacy of healthcare systems while keeping patient data private. Daniel Kraft [11] stated mining as a Poisson process with time-dependent intensity and used this model to derive predictions about block times for various hash-rate scenarios. Tomaso Aste [12] published a paper that provides basic concepts of blockchain and also presented the challenges, the future opportunities and the foreseeable impact of blockchain and distributed ledger technologies in the industry and society.

In this digital era, there is no proper method to curtail fake degrees by securing the marks memos on a tamper-proof platform and verifying them digitally using unique id. In this paper, a method is proposed to store, secure, and verify the credentials of graduates through blockchain technology.

3. Existing Method:

In the presently existing system marks memos are issued directly to the students as a hard copy. There is no digitalized way to verify the certificate. Once the certificate is distributed among the students, there will be no connection between students, university and the certificate. There is no platform to store the certificate safely and verify them when required. Therefore fake graduation degree certificates are created to get backdoor jobs. In industries, once an employee is hired they require a background check of the
educational details of the employee, and this verification is done just manually by their HR team or by some third party. There may be a delay in the process and a chance to manage the university or college staff who receive the verification calls. Sometimes it is even unable to distinguish the fake and original degrees if the master register has already tampered. Some universities store certificates in digital form but are also in a centralized network where there is a chance of tampering the certificate. Therefore this may increase the cases of fraud since there is no means of security and integrity of the data both in manual and in digital form. The main reasons behind this problem are the lack of timestamp facility and method of storing data at a central storage.

Figure 1 explains the existing method from the admission stage of a student to the verification of the credentials of a graduate by the employers. The various stages are mentioned as follows:

1. Join/ Admit: Students admitted to a University/Affiliated College/Autonomous College.
2. Results: After the semester/year-end examinations Results are stored in a register/server.
3. Degree: Issue of Marks Statements/Original Degree in paper form.
4. Transformed: Now the students are transformed to graduates with a degree in hand.
5. Recruited: Graduates are given a suitable job by Employers/Recruiters.
6. Verification Request: Employers request Universities to verify the credentials of the employee.
7. Retrieve: Universities retrieve data from the master register or a central server for verification.
8. Validate: Compare the given data with the retrieved one to validate it and report it to the employer.
9. Confirm/Reject: Based on the report received, confirm/cancel the appointment of the graduate.

4. Proposed System:

Since certificate storage and its security is a matter of concern to the university, students, and employers, the proposed system provides a platform to store and verify the student credentials using Blockchain technology. Whenever a certificate is added into a block, it will return a unique certificate Id along with student Aadhar card number as Primary key. With the help of the unique certificate id student can verify the certificate and also the company can verify whether the certificate provided by the student is authorized or not. Apart from that, there will be an Aadhar card number of each student, by using which verifier can see all the certificates listed in the name of the same person and will be easy to verify individually. In the process to add the certificate, the certificate authority has to pay some Ethereum gas value which will be reduced from the certificate authority account. This is needed for the miners which will later help to add the blocks in the blockchain in return for which they are awarded these Ethereum coins. As the blockchain is distributed in nature and is popularly known as a distributed ledger, it is not easy to tamper the data stored in a block. Though not impossible, it becomes harder and harder to insert
new data or modify the existing data as the length of the chain increases. It also acts as a bridge between institutions and industries. The institutions can store the candidates’ academic credentials on this safe platform. And on the other hand, the industries can verify them by using the transaction id and unique candidate id like the aadhar card number.

The advantages of this application are:

1. No one can tamper or create any fake degrees.
2. Employer verification becomes easy and seamless.

Each Block contains:

| Nonce     |
|-----------|
| Student Id|
| Marks Statement |
| Time Stamp |
| Hash of the Previous Block |

In the proposed system, every block contains the information shown in Fig. 2. The fields are selected to include the necessary information and may vary depends upon the requirements.

1. Nonce: A random value added by the miner to solve the hash puzzle
2. Student Id: Aadhar Id.
3. Marks Statement: The details like Roll No., Name, Class, Subjects and Marks are entered in text format.
4. Time Stamp: Date and Time of creation of the block
5. Hash Value: The cryptographic hash value, which is calculated using SHA-256, of the previous block to link this new block to the existing chain

This system will maintain the integrity and security of the certificates and helps to avoid fake certificate generation. If all the companies and universities start using this portal, there will be no way to create a fake certificate and deceive the recruiter company or any further verifier. Even the timestamp will show the exact time of the certificate generated that will cover an extra layer in the security to the university certificate generation process. The proposed system acts as an overlay to the existing method of issuing physical or digital certificates by the universities and autonomous colleges.

As shown in Fig. 3, the blocks are created and attached to the chain by the Certificate authorities(Universities / Autonomous Colleges) and the copies of the blockchain are distributed among the peer nodes of the corresponding universities and autonomous colleges. While adding the credentials
to the blockchain, every entry will get a unique transaction id(address) which can be further quoted whenever required to retrieve or verify the data along with his aadhar id. Through the application designed, the veriers(recruiting companies) can access the blockchain and complete the process within no time, reliably, and also can get the details of that particular employee id.

4.1 Data Intervening Proposed:

In this paper, a method of data uploading, called Data Intervening, is proposed to facilitate the uploading of alumni data. The concept of Data Intervening is explained with a simple example as shown in Fig. 4. In this case, the Institute needs to upload data from the year of inception, say 2016–2017, then it is proposed to initiate the blockchain from a reference academic year, say 2018–2019, upload the data of one year forward and one year backward as shown in the Figure. After reaching the year of inception, data uploading can be streamlined and continue in a normal way. This method helps even very old universities can include their alumni data without any hurry.

4.2 Why Blockchain?

One has to check some parameters before applying the blockchain technology to solve any existing problem. They are:

1. Are multiple parties involved in the data exchange?
2. Do different parties update data?
3. Is it required to verify the data stored?
4. Do the process of verification takes significant time and money?
5. Is the time stamp of the data has any significance?
6. Are the transactions of various parties depends on one another?

If at least 4 of the six above questions got the answer ‘Yes’, then it is apt to go with blockchain implementation. In this credentials securing and verification system, almost all questions get the answer ‘Yes’. Hence it clearly shows that the problem of fake certificates and delays in the verification process can be solved using blockchain technology.

5. Implementation And Results:

The proposed system is implemented and tested by using the following softwares: JavaScript, Truffle, Solidity, Ganache, Ethereum and Chrome extension Metamask. Ganache is part of the Truffle ecosystem. Ganache is used for the development of DAPP(distributed application, a blockchain) and once it is developed and tested on ganache, it can be deployed on ethereum client like geth or parity. Truffle helps
to develop, test and deploy the DAPP. Metamask is one of the digital currency wallets to store and transact on Ethereum using Ethereum based tokens.

5.1 Features of the implemented prototype:

- This application provides a tamper-proof platform to universities and autonomous colleges to publish the results and also to verify the marks memos submitted by the students to the employers.
- The marks are stored in text format. The consortium of colleges and universities manage this blockchain.
- Students who want to store their academic details on this authorized platform should approach the consortium.
- This distributed ledger (blockchain) keeps track of every academic detail of the student from X class to graduation/post-graduation.
- Only the authorized users can add marks into the blockchain.
- The credentials of the students are added along with roll number, name, marks, and unique id like aadhar number.
- All the generated certificates are attached with an individual certificate-id and this certificate-id is the unique id used for verification.
- If anyone wants to check how many certificates are generated on a particular aadhar number, then by entering aadhar number, a report will show all the certificates generated on the particular name and aadhar number.

5.2 Glossary:

Certificate authority: The person who is permitted to generate the marks memo.

Certificate verifier: The person who verifies the certificates and gets the list of certificates with respect to the aadhar card number.

Web User Interface: An application that can be accessed by the user using any standard web browser and Internet Connection.

Transaction id: A unique hash id generated when a marks memo is uploaded. This is displayed on the digital marks memo which is generated.

Gas Value: Gas refers to the charge required to successfully execute an instruction or a transaction on the Ethereum blockchain platform to avoid infinite execution.

Wallet: To trade with ether, the wallet is a location to store and spend it in the crypto-currency world. It is nothing but a piece of code that allows to store the funds, perform transactions and check the balance whenever needed.
5.3 Results and Testing:

The student data is get entered into the blockchain when the add button is pressed by the certificate authority from the home page. The data entry form receives complete details of the student and generates a certificate with a unique id. The certificate is generated as shown in figure 5. The certificate can be verified by the recruiters using the unique id on the certificate, whenever required. The blockchain is created by storing the data in text format to simplify the testing process. There are other methods of blockchain creation, as well. They are 1. by including hash values of the marks statements, 2. by including the root of the Merkle tree which represents an entire batch of student marks statements. The pros and cons of these methods can be discussed later and are not covered in this paper.

6. Conclusion & Future Work:

The proposed system is a consortium blockchain among universities, their affiliated colleges, autonomous colleges and the companies. Typically universities first add the students' certificates and subsequently the companies or any other verifier can verify the credentials by using student’s aadhar number or transaction id of the certificate. The data stored in a blockchain will be protected as no one can tamper it or add new transactions to it with a back date. The generated unique id for each transaction is later used to verify the certificates. This system can be used by all the universities and colleges, in order to provide extra security to the certificates and the students' data. The problem of fake certificates can be eradicated and no question of its validation. In the future, this can be extended to provide integrity to any type of documents not only to the education sector but also to government sectors where a digital document time stamp is required. Not only to store the student marks information but also to store their employment and experience data, and can also be tracked by using this proposed system. The pros and cons of creating blockchain using hash values of image or pdf format of the marks statements and also the merkle tree method can be discussed.

Abbreviations

CA: Certificate Authority; CrowdBC: Crowd Blockchain; DAPP: Distributed Application; DNN: Deep Neural Network; ECC: Elliptic Curve Cryptography; SHA: Secure Hash Algorithm

Declarations

Acknowledgments:

The authors would like to acknowledge the efforts of K.V. Mounika, Bikesh Kumar Yadav and Nand Kishore Pd Chauhan, from IV B.Tech(CSE), Aditya Engineering College - Surampalem, in implementing the prototype for verification of the results and efficacy of the proposed method.

Funding:
Not applicable.

**Availability of data and materials:**

The data used to test the prototype is taken randomly. The documentation and source code are available with corresponding author upon reasonable request.

**Competing interests:**

The authors declare that they have no competing interests.

**Authors’ contributions:**

RR proposed the basic idea of applying blockchain technology to secure and verify the credentials and contributed more in preparing the final draft. RS and RCh has driven the implementation of prototype to verify the efficacy of the model. LR and BA has tested the functionality of the prototype. All the authors reviewed the draft. They all read and approved the final manuscript.
