In this work we propose a practical entanglement classification scheme for pure states of $2 \times L \times M \times N \times H$, under the stochastic local operation and classical communication (SLOCC), which generalizes the method explored in the entanglement classification of $2 \times L \times M \times N$ to the five-partite system. The entangled states of $2 \times L \times M \times N \times H$ system are first classified into different coarse-grained standard forms using matrix decompositions, and then fine-grained identification of two inequivalent entangled states with the same standard form are completed by using the matrix realignment technique. As an practical example, entanglement classes of the five-qubit system of $2 \times 2 \times 2 \times 2 \times 2$ are presented.

I. INTRODUCTION

Entanglement is an essential feature of quantum theory, and now has been considered to be the key physical resource of quantum information sciences. Many non-classical applications can only be implemented when entangled states are explored, e.g., quantum teleportation [1], dense coding [2,3], and some of the quantum cryptography protocols [4]. However, many superficially different quantum states may have actually the same function when being applied to carry out the quantum information tasks. It is known that, if two entangled states are interconnected by invertible local operators, i.e., equivalent under stochastic local operation and classical communication (SLOCC), then they would be both applicable for the same quantum information tasks. While there are only two SLOCC inequivalent tripartite entanglement classes in three-qubit system [5], the equivalent classes turn to infinite when the system consists more than three partite.

The entanglement classification under SLOCC is generally a difficult problem as the particles and dimensions of each partite grows, though it would be much easier when the entangled states has particular symmetries [6]. At present, nine inequivalent families of quantum systems for four-qubit states under SLOCC have been identified [7]. The equivalence of two quantum states falling into the same entanglement family.

In this work, we generalize the method in [14] to the case of five-partite system of $2 \times L \times M \times N \times H$. The five-partite system with one qubit is first partitioned into tri-partite in form of $2 \times (L \times M) \times (N \times H)$, and the standard forms of inequivalent entanglement classes of $2 \times (L \times M) \times (N \times H)$ behave as the entanglement families of $2 \times L \times M \times N \times H$. Then the matrix realignment is utilized to determine the equivalence of two entangled states and the connecting matrices between them within the same family. The content goes as follows, in Sec.II, the classification procedures of $2 \times L \times M \times N \times H$ are presented. In Sec.III, the classification of the five-qubit system is given as a concrete example, where detailed comparisons with the results in literature are also presented. Summary are concluded in Sec.IV.

II. THE ENTANGLEMENT CLASSIFICATION OF PURE SYSTEM OF $2 \times L \times M \times N \times H$

A. The representation of five-partite states

Every quantum state $|\psi\rangle$ of five-partite system $2 \times L \times M \times N \times H$ may be formulated as the following

$$|\psi\rangle = \sum_{i,m,n,l,h=1}^{2,M,N,L,H} \gamma_{ilmnh} |i,m,n,l,h\rangle , \quad (1)$$

where $\gamma_{ilmnh} \in \mathbb{C}$ are coefficients of the state in representative bases. Therefore, the quantum state $|\psi\rangle$ may also be represented as a high dimensional complex tensor $\psi$ whose matrix elements are $\gamma_{ilmnh}$. In this form, the SLOCC equivalence of two quantum states $\psi'$ and $\psi$ may be formulated as [6]

$$\psi' = A^{(1)} \otimes A^{(2)} \otimes A^{(3)} \otimes A^{(4)} \otimes A^{(5)} \psi , \quad (2)$$

*Corresponding author, qiaocf@ucas.ac.cn
here $A^{(1)} = \mathbb{C}^{2 \times 2}$, $A^{(2)} = \mathbb{C}^{L \times L}$, $A^{(3)} = \mathbb{C}^{M \times M}$, $A^{(4)} = \mathbb{C}^{N \times N}$, $A^{(5)} = \mathbb{C}^{H \times H}$ are invertible matrices of $2 \times 2$, $L \times L$, $M \times M$, $N \times N$, $H \times H$ separately, which act on the corresponding particles.

For the sake of clarity, the quantum state $\psi$ may also be formulated as $\psi = \begin{pmatrix} \Gamma_1 \\ \Gamma_2 \end{pmatrix}$, and

$$(\Gamma_1, \Gamma_2) = \begin{pmatrix} \gamma_{11111} & \gamma_{11112} & \cdots & \gamma_{111NH} \\ \gamma_{11211} & \gamma_{11212} & \cdots & \gamma_{112NH} \\ \vdots & \vdots & \ddots & \vdots \\ \gamma_{LM11} & \gamma_{LM12} & \cdots & \gamma_{LMNH} \\ \gamma_{21111} & \gamma_{21112} & \cdots & \gamma_{211NH} \\ \gamma_{21211} & \gamma_{21212} & \cdots & \gamma_{212NH} \\ \vdots & \vdots & \ddots & \vdots \\ \gamma_{2LM11} & \gamma_{2LM12} & \cdots & \gamma_{2LMNH} \end{pmatrix},$$

which is obtained by grouping the particles as $2 \times (L \times M) \times (N \times H)$. Here $\Gamma_i \in \mathbb{C}^{LM \times NH}$, i.e. complex matrices of $LM$ columns and $NH$ rows (we may assume $LM \leq NH$ without loss of generalities).

**B. The entanglement families of $2 \times L \times M \times N \times H$ system**

It is easy to observe that the quantum state of tripartite system of $2 \times LM \times NH$ could also be represented in same form as Eq. (3). Following the method introduced in [14], the SLOCC equivalence of two states $\psi'$ and $\psi$ in Eq. (2) transforms into the following form

$$\psi' = T \otimes P \otimes Q^T \psi,$$

and in the matrix pair representations, we have

$$(\Gamma'_1, \Gamma'_2) = A^{(1)} \begin{pmatrix} PT_1Q \\ PT_2Q \end{pmatrix},$$

here $P = A^{(2)} \otimes A^{(3)}$, $Q^T = A^{(4)} \otimes A^{(5)}$, $T$ stands for matrix transposition, $A^{(1)}$ acts on the two matrices $\Gamma_{1,2}$, and $P$ and $Q$ act on the rows and columns of the $\Gamma_{1,2}$ matrices, accordingly. The SLOCC equivalence of two $2 \times L \times M \times N \times H$ quantum states in Eq. (3) has a similar form to the tripartite $2 \times LM \times NH$ pure state [14]. The differences lies in that $P$ and $Q$ are not only invertible operators but also direct products of two invertible matrices, $A^{(2)}$ and $A^{(3)}$, $A^{(4)}$ and $A^{(5)}$.

Similar as that of [14], we have the following proposition:

**Proposition 1** If two quantum states of $2 \times L \times M \times N \times H$ are SLOCC equivalent then their corresponding matrix-pairs have the same standard forms as that of $2 \times LM \times NH$ under the invertible operators $T \in \mathbb{C}^{2 \times 2}$, $P \in \mathbb{C}^{LM \times LM}$, $Q \in \mathbb{C}^{NH \times NH}$.

This proposition serves as a necessary condition for the SLOCC equivalence of the entangled states of the $2 \times L \times M \times N \times H$ system.

The transforming matrices $T_0$, $P_0$, $Q_0$ for the standard form can be obtained. Generally the transformation matrices for the standard form are not unique. For example, if $T_0$, $P_0$, $Q_0$ are the matrices that transform $\psi$ into its standard form, then the following matrices will do likewise

$$T_0 \otimes SP_0 \otimes (Q_0S^{-1})^T \psi = \begin{pmatrix} E \\ J \end{pmatrix},$$

where $SJS^{-1} = J$, i.e. $[S, J] = 0$. The nonuniqueness comes from the symmetries of standard forms.

**C. The entanglement classification of a $2 \times L \times M \times N \times H$ system**

As the main result of the paper, we present the following theorem.

**Theorem 2** Two $2 \times L \times M \times N \times H$ quantum states $\psi$ and $\psi'$ are SLOCC equivalent if and only if their corresponding matrix-pair representations have the same standard forms of $2 \times LM \times NH$ and the transformation matrices $P$ and $Q$ in Eq. (4) have the form of direct products of two invertible matrices, i.e., $P = A^{(2)} \otimes A^{(3)}$ and $Q^T = A^{(4)} \otimes A^{(5)}$.

**Proof:** If two $2 \times L \times M \times N \times H$ quantum states $\psi$ and $\psi'$ are SLOCC equivalent, we have

$$\psi' = A^{(1)} \otimes A^{(2)} \otimes A^{(3)} \otimes A^{(4)} \otimes A^{(5)} \psi,$$

here $A^{(i)}$ is invertible matrix, $i \in \{1, 2, 3, 4, 5\}$. According to Proposition 1 we have

$$\psi' = T \otimes P \otimes Q^T \psi,$$

which means that $\psi'$ and $\psi$ have the same standard form of $2 \times LM \times NH$. Combining Eq. (7) and Eq. (5) yields

$$T^{-1} A^{(1)} \otimes (P^{-1}(A^{(2)} \otimes A^{(3)})) \otimes (Q^T)^{-1} A^{(4)} \otimes A^{(5)}) \psi = \psi.$$

As the unit matrices $E \otimes E \otimes E$ must be one of the operators which stabilizes the quantum state $\psi$ in the matrix-pair form, $P$ and $Q$ have the solution of $P = A^{(2)} \otimes A^{(3)}$ and $Q^T = A^{(4)} \otimes A^{(5)}$.

If the two quantum states have the same standard form, then we will have Eq. (3). And if further $P$ and $Q$ have the decomposition of $P = P_1 \otimes P_2$ and $Q = Q_1 \otimes Q_2$ where $P_1 \in \mathbb{C}^{L \times L}$, $P_2 \in \mathbb{C}^{M \times M}$ and $Q_1 \in \mathbb{C}^{N \times N}$, $Q_2 \in \mathbb{C}^{H \times H}$. As matrices $P$ and $Q$ are invertible if and only if both $P_1$ and $P_2$, $Q_1$ and $Q_2$ are invertible, thus

$$\psi' = T \otimes (P_1 \otimes P_2) \otimes (Q_1 \otimes Q_2)^T \psi.$$
Therefore $\psi'$ and $\psi$ are SLOCC equivalent entangled states of a $2 \times L \times M \times N \times H$ system. Q.E.D.

Thus the classification procedure may stated as follows. First, we constructed the standard forms of the $2 \times LM \times NH$ system, which behave as the entanglement families of $2 \times L \times M \times N \times H$ and the transforming matrices $T_0$, $P_0$, $Q_0$ are also obtained. If two quantum states transform into different families, they are SLOCC inequivalent. Otherwise, the connecting matrices of the same family may also be constructed by using the matrix realignment technique [14]. Finally the theorem [2] provides the complete entanglement classification for the two entangled states. In the following, we give detailed examples for $2 \times 2 \times 2 \times 2$ quantum system as the application of our method.

### III. ENTANGLEMENT CLASSIFICATION OF $2 \times 2 \times 2 \times 2$ SYSTEM

There are totally 32 inequivalent families for the genuine $2 \times 2 \times 2 \times 2$ entangled classes according to our method; the genuine entangled families of $2 \times 2 \times 2 \times 2$ quantum states are listed as follows. The $\mathcal{N}_f(22222) = 32$ families includes:

- two families from $2 \times 2 \times 2$ system (GHZ and W),
  \[ |\psi\rangle = |1(11)(11)\rangle + |2(22)(22)\rangle, \]
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(22)(22)\rangle + |2(11)(22)\rangle, \]
- two families from $2 \times 2 \times 3$ system,
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |2(12)(21)\rangle, \]
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |2(11)(12)\rangle + |2(12)(21)\rangle, \]
- one family from $2 \times 2 \times 4$ system,
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |2(11)(21)\rangle \]
  \[ + |2(12)(22)\rangle, \]
- six families from $2 \times 3 \times 3$ system,
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |2(12)(21)\rangle, \]
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |2(11)(21)\rangle + |2(12)(21)\rangle, \]
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |2(12)(12)\rangle + |2(21)(21)\rangle, \]
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |2(11)(12)\rangle + |2(21)(21)\rangle, \]
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |2(12)(21)\rangle + |2(21)(11)\rangle, \]
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |2(12)(21)\rangle + |2(11)(21)\rangle, \]
  five families come from $2 \times 3 \times 4$ system,
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |1(21)(21)\rangle + |2(21)(22)\rangle, \]
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |1(21)(21)\rangle + |2(11)(12)\rangle + |2(21)(22)\rangle, \]
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |1(21)(21)\rangle + |2(12)(21)\rangle + |2(21)(22)\rangle, \]
  \[ |\psi\rangle = |1(11)(11)\rangle + |1(12)(12)\rangle + |1(21)(21)\rangle + |2(12)(21)\rangle + |2(21)(22)\rangle. \]

The other 16 families come from the standard forms of a $2 \times 4 \times 4$ system. Among the 16 standard forms of $2 \times 4 \times 4$, there also exist the continuous entanglement families. That is, different entanglement families arise from the different values of the characterization parameters. We have proved that the standard forms with the continuous parameters belonging to the same entanglement class of $2 \times 4 \times 4$ system, correspond to different entanglement families of $2 \times 2 \times 2 \times 2$ system.

In addition, a necessary condition for the genuine entanglement of a $2 \times L \times M \times N \times H$ system is that all dimensions of the five particles shall be involved in the entanglement, requiring that $LM \leq 2NH$ with assuming the larger value of the dimensions to be $LM$. The scheme works better for higher dimensions, especially in the case of $LM = NH$.

### IV. SUMMARIES

In conclusion, we have proposed a practical classification scheme for the entangled states of $2 \times L \times M \times N \times H$ pure system under SLOCC. By using the standard forms of $2 \times LM \times NH$, the entangled families of $2 \times L \times M \times N \times H$ are obtained. And the invertible local operators that connecting two quantum states in the same family may also be constructed by using the matrix realignment technique. This provides a necessary and sufficient condition on the SLOCC equivalence of the two quantum states. As an application, detailed examples of the entanglement classification under SLOCC for five-qubit system is presented, which has not been discussed systematically in the literature to the best of our knowledge.
