Nanostructured N doped TiO₂ efficient stable catalyst for Kabachnik–Fields reaction under microwave irradiation†
Sachin P. Kunde,a Kaluram G. Kanade,a, Kabasaheb K. Karale,a Hemant N. Akolkar,b Sudhir S. Arbuj,c Pratibha V. Randhavane,a Santosh T. Shinde,a Mubarak H. Shaikha and Aniruddha K. Kulkarnie

Herein, we report nitrogen-doped TiO₂ (N-TiO₂) solid-acid nanocatalysts with heterogeneous structure employed for the solvent-free synthesis of α-aminophosphonates through Kabachnik–Fields reaction. N-TiO₂ were synthesized by direct amination using triethylamine as a source of nitrogen at low temperature and optimized by varying the volume ratios of TiCl₄, methanol, water, and triethylamine, under identical conditions. An X-ray diffraction (XRD) study showed the formation of a rutile phase and the crystalline size is 10 nm. The nanostructural features of N-TiO₂ were examined by HR-TEM analysis, which showed they had rod-like morphology with a diameter of ~7 to 10 nm. Diffuse reflectance spectra show the extended absorbance in the visible region with a narrowing in the band gap of 2.85 eV, and the high resolution XPS spectrum of the N 1s region confirmed successful doping of N in the TiO₂ lattice. More significantly, we found that as-synthesized N-TiO₂ showed significantly higher catalytic activity than commercially available TiO₂ for the synthesis of a novel series of α-aminophosphonates via Kabachnik–Fields reaction under microwave irradiation conditions. The improved catalytic activity is due to the presence of strong and Bronsted acid sites on a porous nanorod surface. This work signifies N-TiO₂ is an efficient stable catalyst for the synthesis of α-aminophosphonate derivatives.

1 Introduction

In recent years, organophosphorus compounds have received much attention due to their widespread applications in medicinal and agriculture industries.α,β,γ α-Aminophosphonates are one such biological important framework that are structural mimics of amino acids. For example, glyphosate (N-(phosphonomethyl)glycine) is extensively utilized in agriculture as a systemic herbicide and Alafosfalin is used as an antibacterial agent (Fig. 1). The bioactivity of these molecules such as antimicrobial,α antioxidant,γ anti-inflammatory,ε enzyme inhibitorsγ and antibacterialε is one of the reasons for them to be of immense interest in synthetic organic chemistry. It has been demonstrated that on incorporation of heterocycles such as thiophene,δ benzothiazoles,ε thiadiazoles,ζ and pyrazoleε into the α-aminophosphonate scaffold, the resulting compounds exhibited interesting biological activities. Pyrazole derivatives of α-aminophosphonates have been rarely reported in the literature,κ,λ thus synthesis of novel pyrazole derivatives of α-aminophosphonates is important to research.

Although several protocols for the synthesis of α-aminophosphonates are reported, one of the most important is the Kabachnik–Fields reaction.µ,ν This involves a one-pot three-component coupling of a carbonyl compound, an amine and alkylphosphite. These protocols has been accomplished in presence of a variety of catalyst such as TiCl₄,θ CuI,θ hexafluorosulphonic sodium salt,υ trifluoroacetic acid (TFA),θ In(OTf)₃,θ BiCl₃,θ Cu(OTf)₂,θ SbCl₃/Al₂O₃,θ InCl₃,θ LiClO₄,θ ZrOCl₂,θ TsCl,θ Mg(ClO₄)₂,θ and Na₂CaP₂O₆ in presence or

TiO₂ was attained by full and earth-abundant. It has been proven the desired property of environmental compatibility, inexpensive, safe, stable, reusable potential titania catalyst attracted in organic synthesis due to its the use of nanocrystalline titania (TiO₂) has been extensively owing to their outstanding physiochemical properties, which furnished their wide applications in sensors, pigments, photovoltaic cells, and catalysis. Among all transition metal oxides the use of nanocrystalline titania (TiO₂) has been grown extensively owing to their outstanding physiochemical properties, which furnished their wide applications in sensors, pigments, photovoltaic cells, and catalysis. Also, the use of potential titania catalyst attracted in organic synthesis due to its environmental compatibility, inexpensive, safe, stable, reusable and earth-abundant. It has been proven the desired property of TiO₂ was attained by fulfilling requirements in terms of unique morphology, high crystallinity and mixed-phase composition, the ability of oxidizing and reducing ability under suitable irradiation makes promising greener alternative approach towards important organic transformations compared to other expensive, toxic, transition metal oxides. Moreover, the phase composition and the degree of crystallinity of the titania sample plays an important role in catalytic activity. In the past several organic transformations such as oxidation of primary alcohols, synthesis of xanthenes, Friedel–Crafts alkylation, Beckmann rearrangement efficiently utilizes TiO₂ as a heterogeneous reusable catalyst. In the literature several reports have been debated to influence nitrogen doping on photocatalytic activity of nanocrystalline TiO₂. However, the effect is unrevealed for catalytic applications in organic synthesis. Recently, Hosseini-Sarvari explored the use of commercial TiO₂ in the synthesis of α-aminophosphonates via Kabachnik–Fields reactions.

In present investigation, we have prepared nanostructured N doped TiO₂ and also investigation emphasis was given on the synthesis of a series of a novel diethyl(1-phenyl-3-(thiophen-2-yl)-1H-pyrazol-4-yl)(phenylamin) methylphosphonates under microwave irradiation.

2 Experimental sections

2.1 Synthesis of N doped TiO₂ nanorods

The nanostructured N-TiO₂ were synthesized by previously reported method with some modification. In a typical procedure, 0.5 mL of titanium tetrachloride (TiCl₄) was added in absolute methanol (25 mL) with constant stirring at room temperature. To this solution requisite quantity a 0.1–2 M aqueous triethylamine solution is injected rapidly. The resulting solution was refluxed for 24 h with constant stirring. The white precipitate formed was collected and washed with ethanol several times followed by centrifugation (10 000 rpm for 20 min). The precipitate was dried at 473 K for 24 h. To control the final morphologies of samples, the sample were synthesized as function of volume ratio of TiCl₄, methanol, water, and triethylamine. The sample prepared in volume ratio 1 : 10 : 50 : 0, 1 : 10 : 50 : 1, 1 : 10 : 50 : 2, 2 : 10 : 50 : 2, and 2 : 10 : 50 : 4 were denoted as TN0 (pure TiO₂), TN1, TN2, TN3 and TN4 respectively.

2.2 Synthesis of 1-phenyl-5-(thiophen-2-yl)-1H-pyrrole-3-carbaldehyde

1-Phenyl-5-(thiophene-2-yl)-1H-pyrrole-3-carbaldehyde were obtained via the Vilsmeier–Haack reaction of the appropriate phenylhydrazones, derived from the reaction of 2-acetyl thiophene with phenylhydrazine (Scheme 1).

2.3 Synthesis of diethyl(1-phenyl-3-(thiophene-2-yl)-1H-pyrazole-4-yl)(phenylamino)methylphosphonates

In a typical procedure, the pyrazolealdehyde 1 (1 mmol), aniline 2 (1 mmol), triethyl phosphate 3 (1.1 mmol) and N-TiO₂ (12 mol%) were taken in a round bottom flask equipped with a condenser and subjected to microwave irradiation for (10–15 min) using 420 W (RAGA’s Microwave system) (Scheme 3). The
progress of the reaction was monitored by TLC. After the reaction was completed, the reaction mixture extracted using ethyl acetate and insoluble catalyst separated by filtration. The crude product was purified by silica gel column chromatography using n-hexane/ethyl acetate as eluent. The product structure was determined by FTIR, $^1$H NMR, and LS-MS.

2.4 Samples characterization

The phase purity and crystallinity were examined by X-ray diffraction (XRD) technique (Advance, Bruker AXS D8) using Cu Kα1 (1.5406 Å) radiation with scanning 2θ range from 20 to 80°. For FETEM analysis samples were prepared by evaporating dilute solution on carbon-coated grids. FE-TEM measurements were carried using the JEOL SS2200 instrument operated at an accelerating voltage of 300 kV. The Brunauer-Emmett-Teller (BET) surface area of nanocatalysts was examined using the Quantachrome v 11.02 nitrogen instrument. The optical properties of the powder samples were studied using UV-vis diffuse reflectance absorption spectra (UV-DRS) were recorded on the Perkin-Elmer Lambda-950 spectrophotometer in the wavelength range of 200–800 nm. Powder samples were used for XPS measurements. The XPS measurements of powdered samples were carried out on a VG Microtech ESCA3000 instrument. Fourier transform infrared (FTIR) spectra of prepared samples were recorded on a Shimadzu Affinity 1-S spectrophotometer in the range of 400–4000 cm$^{-1}$. $^1$H NMR was recorded in DMSO-$d_6$ solvent on a Bruker Advance-400 spectrometer with tetramethylsilane (TMS) as an internal reference.

3 Results and discussions

3.1 Structural study

Nanostructured TiO$_2$ and N doped TiO$_2$ were synthesized by a simple refluxing method. The phase purity and phase formation of as-synthesized material were analysed by powder X-ray diffraction pattern. Fig. 2 compares powder XRD patterns of TiO$_2$ and N doped TiO$_2$ samples. The peak position and peak intensity of the pure TiO$_2$ samples can be indexed into rutile phases (Fig. 2). Further, it is observed that an increase in the amount N-dopant (triethylamine) the intensity of the diffraction

| Sample | Surface area (m$^2$ g$^{-1}$) | Pore volume (cm$^3$ g$^{-1}$) | Pore radius (Å) |
|--------|-----------------------------|-----------------|----------------|
| TN0    | 21.956                      | 0.051           | 18.108         |
| TN2    | 40.359                      | 0.215           | 30.811         |
| TN4    | 53.589                      | 0.101           | 18.041         |

Table 2 BET specific surface area and pore size distribution of TiO$_2$ and N-TiO$_2$
peaks of the rutile phase decreases, while that of anatase phase increases, indicating that the fraction of the anatase phase gradually increases at the expense of the rutile phase during this condition (sample TN2–TN4). The phase composition of rutile and anatase phase of TiO₂ evaluated from the peak intensity using the following equation,

\[ f_A = \frac{1}{1 + \frac{1}{K_2} \frac{I_R}{I_A}} \]

where \( f_A \) is the fraction of the anatase phase, and \( I_A \) and \( I_R \) are the intensities of the anatase (1 0 1) and rutile (1 1 0) diffraction peaks, respectively. The higher molar concentration of triethylamine is favourable for the transformation from rutile to anatase. Therefore, the phase composition of TiO₂ samples, i.e. the fraction of anatase and rutile, can be facilely controlled through adjusting the concentration of triethylamine. The slight shift of rutile (1 1 0) diffraction peaks towards a higher angle with an increase in the amount of N dopant suggesting the incorporation of nitrogen in the TiO₂ crystal structure. The crystallite size is calculated from each (1 1 0) peak in the XRD pattern using the Sherrer formula. The average crystalline size are 25, 19, 16, 12 and 9 nm for TN0, TN1, TN2, TN3, and TN4 respectively (Table 1). From, XRD analysis it is clear that with an increase in the concentration of nitrogen in TiO₂, fraction of anatase increases phase and crystalline size decreases.

### 3.2 Surface and morphological study

Transmission electron microscopy (TEM) and high-resolution transmission electron microscopy (HRTEM) analysis were performed to study morphology and crystallinity of as-synthesized pure and N doped TiO₂ materials (Fig. 3). The pure TiO₂ (TN0) sample seems flowerlike nanostructures (Fig. 3a). At high-resolution it reveals that each flower microstructure consisting several nanorods. The length of nanorods are in the range of 50–70 nm and diameter is about 10–15 nm (Fig. 3b). Fig. 3c shows the lattice fringes of the material with interplanar spacing \( d \) spacing 0.33 nm matches well (1 0 0) plane of rutile TiO₂. Fig. 3c inset shows a selected area diffraction pattern in which bright spots observed that confirm the TiO₂ nanorods are in nanocrystalline nature. It was observed that addition of N dopant, resulting sample TN1 and TN2 grows into new superstructure consisting nanorods of length 30–50 nm and spheres.
of diameter 20–30 nm, particles size is obviously smaller than TN0 (Fig. 3d and h). HRTEM results are consistent with XRD results. The d-spacing is about 0.325 Å between adjacent lattice planes of the N doped TiO2.

It was revealed that with doubling concentration of TiCl4, sample TN3 and TN4 were grown into very fine agglomerated nanorods (Fig. 4). Further, it is observed that these nanorods having size in length 30–40 nm and diameter is around 7–10 nm which is lower than pure TiO2. Fig. 4f inset shows selected area diffraction pattern shows, surprisingly, ring-like pattern unlike TiO2, indicates N-TiO2 nanorods are in polycrystalline nature. From HR-TEM results it is concluded that increase in concentration of TiCl4 and triethylamine reduces the size of the nanorods.

The specific surface area of as-prepared samples was studied by (N2) nitrogen gas adsorption–desorption measurement at 77 K using the Brunauer–Emmett–Teller (BET) method. The N2 adsorption–desorption isotherm of N-TiO2 nanoparticles is shown in Fig. 5. The pure TiO2 shows type IV isotherm according to IUPAC classification, which are typical characteristics of a material with pore size in the range of 1.5–100 nm Fig. 5a. Cation, TiO2. indicates N-TiO2 nanorods are in polycrystalline nature. It was revealed that with doubling concentration of TiCl4, sample TN3 and TN4 were grown into very fine agglomerated nanorods (Fig. 4). Further, it is observed that these nanorods having size in length 30–40 nm and diameter is around 7–10 nm which is lower than pure TiO2. Fig. 4f inset shows selected area diffraction pattern shows, surprisingly, ring-like pattern unlike TiO2, indicates N-TiO2 nanorods are in polycrystalline nature. From HR-TEM results it is concluded that increase in concentration of TiCl4 and triethylamine reduces the size of the nanorods.

The specific surface area of as-prepared samples was studied by (N2) nitrogen gas adsorption–desorption measurement at 77 K using the Brunauer–Emmett–Teller (BET) method. The N2 adsorption–desorption isotherm of N-TiO2 nanoparticles is shown in Fig. 5. The pure TiO2 shows type IV isotherm according to IUPAC classification which are typical characteristics of a material with pore size in the range of 1.5–100 nm (Fig. 5a). The shape of the hysteresis loop is H3 type which may associate due to the agglomeration of nanoparticles forming slit-like pores, reflected in TEM images. At higher relative pressure (p/p0) the slope shows increased uptake of adsorbate as pores become filled; inflection point typically occurs near completion of the first monolayer. The BET surface area of pure TiO2 is found to be 21.956 m² g⁻¹. The pore size distribution of prepared samples was investigated by Barrett–Joyner–Halenda (BJH) method Fig. 5(a)–(c) insets. The average pore diameter of pure TiO2 nanoparticles is 18 nm which demonstrates the material is mesoporous nature. Further, it is observed that the incorporation of nitrogen in TiO2 nanoparticles the surface area shifts towards higher values. The adsorption–desorption isotherms of nitrogen-doped TiO2 samples display the type II isotherm according to IUPAC classification. The specific BET surface area of samples TN2 and TN4 are 40.359 m² g⁻¹ and 53.589 m² g⁻¹ respectively (Fig. 5b and 4c). This observation specifies a decrease in the particle size of TiO2 nanoparticles specific surface area increases which are in consisting of XRD and TEM results. The Brunauer–Emmett–Teller (BET) specific surface areas, pore volumes and mean pore and mean pore diameters of samples TN0, TN2, and TN4 are summarized in Table 2.

3.3 Optical and electronic property studies

The optical property of the as-synthesized material was analyzed by UV-Vis diffuse absorbance spectra as shown in Fig. 6. Fig. 6 displays the comparative UV-DRS spectra of pristine TiO2 and a series of N doped TiO2 samples. The absorption edge for the pure TiO2 (TN0) is observed at around 410 nm (Fig. 6a), which is consistent with the band gap of the rutile phase. The N doped TiO2 nanostructures show strong absorption in the visible region (410–600 nm). The redshift clearly indicates the

successful doping of N in the lattice of TiO2. Moreover, as the concentration of triethylamine increases redshift of N-TiO2 also increases which confirms higher nitrogen doping and a higher fraction of absorption of photons from the visible region. The band gap of as-synthesized material calculated by using the Tauc plot shown in Fig. 6 (insets). The band gap \( E_g \) for the sample TN0, TN1, TN2, TN3, and TN4, were observed to be 3.15, 3.09, 3.07, 3.03 and 2.85 eV respectively. The decrease in the band gap is attributed to higher mixing of the (O/N) 2p level is developed in the Ti-3d level falls at the top of the VB, therefore, band gap reduced compared to the pristine TiO2 nanostructure.

### 3.4 FT-IR spectroscopy

Fig. 7 shows comparative FTIR spectra for pure and N doped TiO2. The absorption peak signal in the range of 400–1100 cm\(^{-1}\) is characteristic of the formation of O–Ti–O lattice. The absorption at 668 cm\(^{-1}\), 601 cm\(^{-1}\), 546 cm\(^{-1}\) and 419 cm\(^{-1}\) corresponds to Ti–O vibrations.\(^{48,49}\) Further, for the sample TN1–TN3 the IR bands centred at 1400–1435 cm\(^{-1}\) indicates nitrogen doping in the TiO2 sample. The band located at 1070 cm\(^{-1}\) is attributed to Ti–N bond vibrations. Also, it is observed that the band at 1335 cm\(^{-1}\) for pure TiO2 is shifted towards longer wavenumber 1430 cm\(^{-1}\) supports for the claim of N doping in TiO2 lattice. Further it is also observed that some of the minor the peaks of pure TiO2 are rather different than the N-doped TiO2, this indicates the incorporation of nitrogen in TiO2 lattices. The peak centered at 1600–2180 cm\(^{-1}\) is ascribed due to –OH stretching frequency. From, IR spectra it is clear that N is successfully incorporated in the lattice of TiO2.

### 3.5 X-ray photoelectron spectroscopy

The XPS were used for chemical identification and electronic state of dopant nitrogen in sample TN2 and TN4. The high resolution XPS spectra of N 1s on deconvolution shows two different peaks at 399.6 and 401.5 eV indicates nitrogen present in two different electronic state (Fig. 8a and b). The peak at 399.6 is attributed to presence of interstitial N or N–Ti–O linkage. The result is consistent with previous reports.\(^{41}\) The peak at 401.5 is attributed to presence of N in oxidized state as NO or NO\(_2\). The concentration of nitrogen on surface of TN2 and TN4 are 2.8% and 3.4% respectively. Fig. 8c shows the peak at 458.8 and 458.3 is attributed to Ti 2p\(_{3/2}\) and Ti 2p\(_{1/2}\) in good agreement the presence of Ti[iv] in TiO2. The peak at binding energy 530.1 and 530.2 eV of sample are attributed to O 1s (Fig. 8d).

### 3.6 Catalytic study in synthesis of α-aminophosphonates

In order to find out the best experimental condition, the reaction of pyrazolaldehyde \(1a\), aniline \(2a\) and triethylphospitite \(3\) under microwave irradiation is considered as standard model reaction (Scheme 2).

In the absence of a catalyst, the standard model reaction gave a small amount of product (Table 3 entry 1). These results specify catalyst is required to occur reaction. In order to check the catalytic utility, the model reaction carried out in the presence of a variety of catalysts (Table 3 entry 2–9). The N-TiO2 NRs gave better results than acetic acid, commercial ZnO and commercial TiO2.

Inspiring these results, we further studied the progress of reaction at different time intervals, we observed the sample N-doped TiO2 catalyzes efficiently than undoped TiO2, and this may be attributed to the higher surface area (Fig. 9A).

The optimum concentration of the catalyst was investigated by performing the model reaction at different concentrations such as 3, 6, 9, 12 and 15 mol%\(^{48,49}\). The reaction yielded in 69, 76, 86, 95 and 95% yields respectively (Table 4). This shows that 12 mol% of TN\(_4\) is adequate for the reaction by considering the yield of the product.

To evaluate the effect of solvents, different solvents such as ethanol, methanol, dichloromethane, THF, 1,4-dioxane and toluene were used for the model reaction in presence of N-TiO2 catalyst. The reaction proceed with better yield in polar protic solvent (Table 5, entries 1, 2). However it was observed that the usage of solvents slows down the rate of reaction and gives the desired product in lower yields than that for neat condition (Table 5, entries 1–6).

The recyclability of the catalyst was then examined and the outcomes are shown in Fig. 9B. After the completion of reaction, the reaction mixture was extracted with ethyl acetate. The residual catalyst was washed with acetone, dried under vacuum at 100 °C and reused for consequent reactions. The recovered catalyst could be used for 5 times without obvious loss of catalytic activity.

The difference between the XRD of fresh catalyst and reused catalyst shown in Fig. 10.

The usefulness of optimized reaction condition for model reaction (12 mmol % of catalyst, solvent-free, MWI) was extended for the synthesis of a series of novel α-aminophosphonates (\(4a\)–\(l\)) by reacting pyrazoldehyde (\(1a\)–\(c\)), anilines (\(2a\)–\(d\)) and triethylphosphate (3) in excellent yields (Scheme 3).
The obtained product 4a–l was characterized by spectroscopic techniques (Table 6).

The spectroscopic data of synthesized compounds are given in ESI (S-2 to S-26).†

### 4 Conclusions

In summary, we have prepared N doped TiO$_2$ nanorods by thermal hydrolysis method using triethylamine as the source of nitrogen at relatively low temperatures. The XRD analysis showed that with varying composition molar ratios of TiCl$_4$, CH$_3$OH, H$_2$O, and (C$_2$H$_5$)$_3$N, phase composition of rutile to anatase also tunes. FTIR spectra show the chemical environment of doping by the formation of the N–Ti–O and Ti–O–Ti bond. The morphological study performed by the FE-TEM technique shows the formation of well-developed nanorods of size in length 30–40 nm and diameter is around 7–10 nm, which is lower than pure TiO$_2$. Further, BET analysis N-TiO$_2$ shows the maximum specific surface area 53.4 m$^2$ g$^{-1}$ which is 2.5 times
higher than pure TiO$_2$. The as-synthesized materials were employed for the synthesis of $\alpha$-aminophosphonates via Kabachnik–Fields reaction under microwave irradiation. The N-TiO$_2$ shows remarkable catalytic activity for aminophosphonate derivatives compared with TiO$_2$ and other similar nanocatalysts.
