Abstract
A coloring is called s-wide if no walk of length $2s - 1$ connects vertices of the same color. A graph is s-wide colorable with $t$ colors if and only if it admits a homomorphism into a universal graph $W(s, t)$. Tardif observed that the value of the $r$th multichromatic number $\chi_r(W(s, t))$ of these graphs is at least $t + 2(r - 1)$ and equality holds for $r = s = 2$. He asked whether there is equality also for $r = s = 3$. We show that $\chi_s(W(s, t)) = s + 2(s - 1)$ for all $s$ thereby answering Tardif’s question. We observe that for large $r$ (with respect to $s$ and $t$ fixed) we cannot have equality and that for $s$ fixed and $t$ going to infinity the fractional chromatic number of $W(s, t)$ also tends to infinity. The latter is a simple consequence of another result of Tardif on the fractional chromatic number of generalized Mycielski graphs.

Keywords
generalized Mycielski graphs, homomorphism, Kneser graphs, multichromatic number, wide coloring

1 | INTRODUCTION

A vertex-coloring of a graph is called $s$-wide if the two endvertices of every walk of length $2s - 1$ receive different colors in it. If every vertex gets a different color then the coloring is $s$-wide if and only if the graph does not contain any odd cycle shorter than $2s + 1$. The interesting phenomenon is that some graphs have $s$-wide colorings that are also optimal colorings.

A 1-wide coloring is just a proper coloring. Two-wide colorings were first investigated by Gyárfás, Jensen, and Stiebitz [5] who, answering a question of Harvey and Murty, showed the existence of a $t$-chromatic graph for every $t \geq 2$ with the additional property...
that it admits a $t$-coloring in which the neighborhood of every color class is an independent set. The analogous statement including more distant neighborhoods is also proved in [5].

Three-wide colorings (that are called simply wide colorings in [17]) turned out to be relevant concerning the local chromatic number of several graph families whose chromatic number can be determined by the topological method of Lovász [10], for more details and also for the relevance of $s$-wide colorability in the context of the circular chromatic number see [17].

A graph homomorphism from a graph $F$ to a graph $G$ is an edge-preserving map of the vertex set of $F$ to the vertex set of $G$. The existence of such a map is denoted by $F \rightarrow G$. It is easy to see that $G \rightarrow K_t$ is equivalent to the $t$-colorability of graph $G$, that is, to $\chi(G) \leq t$, where $\chi(G)$ is the chromatic number of $G$. We refer to the book [7] for a general treatment of the theory of graph homomorphisms.

Several other types of graph colorings can also be expressed by the existence of a graph homomorphism to some target graph and $s$-wide colorability is no exception. It is proved independently in [1,17] (and already in [5] for the $s=2$ case) that $s$-wide colorability with $t$ colors is equivalent to the existence of a homomorphism to the following graph we denote by $W(s,t)$ as in [17].

$$V(W(s,t)) = \{(x_1 \ldots x_t) : \forall i \ x_i \in \{0,1,\ldots,s\}, \exists i \ x_i = 0, \exists j \ x_j = 1\},$$

$$E(W(s,t)) = \{\{(x_1 \ldots x_t), (y_1 \ldots y_t)\) : \forall i \ |x_i - y_i| = 1 \text{ or } x_i = y_i = s\}.$$

**Proposition 1** (Baum and Stiebitz [1], Gyárfás et al. [5], and Simonyi and Tardos [17]).

A graph $G$ admits an $s$-wide coloring using $t$ colors if and only if $G \rightarrow W(s,t)$.

A different incarnation of the graphs $W(s,t)$ appears in the papers [6,21,26], where (following Wrochna’s notation in [26]) a graph operation $\Omega_k$ is given for every odd integer $k$ and when applied to the complete graph $K_t$ for $k = 2s - 1$ then the resulting graph is isomorphic to $W(s,t)$. We will give and make use of this alternative definition in Section 2.

It is easy to see that $W(s,t)$ can be properly colored with $t$ colors: set the color of vertex $(x_1 \ldots x_t)$ to be the unique $i$ for which $x_i = 0$. It is proved in [1,5,17] (cf. also the chromatic properties of the more general $\Omega_k$ construction in [6,21,26]) that this coloring is optimal, that is,

$$\chi(W(s,t)) = t. \quad (1)$$

This represents the surprising fact that there are $t$-chromatic graphs that can be optimally colored in such a way that the complete $d$-neighborhood of any color class is an independent set for every $d < s$. (By $d$-neighborhood of a color class we mean the set of vertices at distance exactly $d$ from the closest element of the color class. In fact, if $G$ is $s$-widely colored then not only the $d$-neighborhoods of color classes form independent sets for $d < s$ but all those vertices that can be attained via walks of length $d$ from the given color class.) The proof of $t$-chromaticity of $W(s,t)$ goes via showing that some other graphs that are known to be $t$-chromatic admit a homomorphism into $W(s,t)$. These graphs include generalized Mycielski graphs, Schrijver graphs, and Borsuk graphs of appropriate parameters (for the definition of generalized Mycielski graphs see Section 3; cf. [3,12,15] for the definition of Schrijver graphs.
and Borsuk graphs and [17] for further details). This shows, in particular, that generalized Mycielski graphs, Schrijver graphs, and Borsuk graphs (of those appropriate parameters) admit s-wide colorings. A common property of all these graphs is that their chromatic number can be determined by the already mentioned topological method introduced by Lovász in his celebrated paper [10] proving Kneser’s conjecture.

For \( n, k \) positive integers satisfying \( n \geq 2k \) the Kneser graph \( KG(n, k) \) is defined on \( \binom{[n]}{k} \), the set of all \( k \)-element subsets of the \( n \)-element set \( [n] = \{1, 2, ..., n\} \) as vertex set. Two vertices are adjacent if and only if the \( k \)-element subsets they represent are disjoint. It is not hard to show that \( \chi(KG(n, k)) \leq n - 2k + 2 \) (for all \( n, k \) satisfying \( n \geq 2k \)) and Kneser [8] conjectured that this estimate is sharp. This was proved by Lovász [10] thereby establishing the following result.

**Theorem** (Lovász–Kneser theorem).

\[
\chi(KG(n, k)) = n - 2k + 2.
\]

For more about the topological method we refer to the excellent book by Matoušek [12].

The existence of a homomorphism to the Kneser graph \( KG(n, k) \) can also be interpreted as a coloring property: \( G \to KG(n, k) \) holds if and only if we can color the vertices of \( G \) with \( n \) colors in such a way that every vertex receives \( k \) distinct colors and if two vertices \( u \) and \( v \) are adjacent then the set of colors received by \( u \) is disjoint from the set of colors received by \( v \). Such colorings were first considered by Geller and Stahl, see [4,18]. Stahl [18] introduced the corresponding chromatic number \( \chi_k(G) \) as the minimum number of colors needed for such a coloring, called a \( k \)-fold coloring and \( \chi_k(G) \) the \( k \)-fold chromatic number in [14] (or \( k \)-tuple chromatic number in [7]). The fractional chromatic number \( \chi_f(G) \) can be defined as

\[
\chi_f(G) = \inf_k \left\{ \frac{\chi_k(G)}{k} \right\} = \inf \left\{ \frac{n}{k} : G \to KG(n, k) \right\}.
\]

Note the immediate consequence of this definition that if \( G \to H \) then \( \chi_f(G) \leq \chi_f(H) \).

As multichromatic numbers generalize the chromatic number (the latter being the special case for \( k = 1 \)), determining their exact value (that is the value of the \( k \)-fold chromatic numbers for various \( k \)'s) can be even more problematic than giving the value of the chromatic number. Indeed, while the chromatic number of Kneser graphs is already known by the Lovász–Kneser theorem, it is only a still open conjecture due to Stahl what homomorphisms exist and what do not between Kneser graphs, see Section 6.2 of [7] for details, cf. also [25].

The starting point of our investigations was a question by Tardif [23] who observed that (1) combined with the Lovász–Kneser theorem implies that

\[
\chi_r(W(s, t)) \geq t + 2(r - 1)
\]
and that equality holds for \( r = s = 2 \). (This is also true in the case of \( r = s = 1 \) when it simply means \( \chi(K_t) = t \).) Tardif asked if there is equality also for \( r = s = 3 \). In particular, he was interested in whether \( W(3, 8) \not\equiv KG(12, 3) \) and/or \( W(3, 7) \not\equiv KG(11, 3) \) is true. Our main result will imply that this is actually not the case and equality does hold for \( r = s = 3 \). The motivation for Tardif’s question came from recent developments concerning Hedetniemi’s conjecture in which wide colorings also turned out to be relevant.

Hedetniemi’s conjecture asked whether the so-called categorical (or tensor) product \( G \times H \) satisfies \( \chi(G \times H) = \min\{\chi(G), \chi(H)\} \). The conjecture is equivalent to say that \( G \times H \rightarrow K_c \) implies that \( G \rightarrow K_c \) or \( H \rightarrow K_c \) must hold. (Although the latter directly only means \( \chi(G \times H) \geq \min\{\chi(G), \chi(H)\} \), the reverse inequality is essentially trivial.) If this holds for \( K_c \), then \( K_c \) is called multiplicative. Hedetniemi’s conjecture formulated in 1966 thus stated that \( K_c \) is multiplicative for every positive integer \( c \). This is trivial for \( c = 1 \) and easy for \( c = 2 \). For \( c = 3 \), it is a far from trivial result by El-Zahar and Sauer [2]. For no other \( c \) it was decided (whether \( K_c \) is multiplicative or not) until 2019, when a breakthrough by Yaroslav Shitov took place who proved in [16] that the conjecture is not true by constructing counterexamples for large enough \( c \)’s. The smallest \( c \) for which Shitov’s construction disproved the conjecture was extremely large (about \( 3^{95} \) according to an estimate in [27]). This value was dramatically improved within a relatively short time. Using Shitov’s ideas in a clever way, Zhu [28] first reduced \( c \) to 125. Then, developing the method further, Tardif [23] showed a counterexample for \( c = 13 \). He remarked that his construction would also work for \( c = 12 \) and \( 11 \), respectively, provided that \( W(3, 8) \not\equiv KG(12, 3) \) and \( W(3, 7) \not\equiv KG(11, 3) \). Our main result is the following that shows as a special case that these homomorphisms do exist.

**Theorem 2.**

\[ \chi_s(W(s, t)) = t + 2(s - 1). \]

Later Wrochna [27] managed to improve on Tardif’s result using the ideas in [23] in a different way and proving that \( K_c \) is not multiplicative for any \( c \geq 5 \) thus leaving \( c = 4 \) the only open case. (For more details about Hedetniemi’s conjecture see, e.g., Tardif’s survey [22] and the more recent papers cited above.)

The paper is organized as follows. We present the proof of Theorem 2 in Section 2. In Section 3 we elaborate on the problem of what we can say about \( \chi_r(W(s, t)) \) for general \( r \). It will be an immediate consequence of Theorem 2 combined with Tardif’s observation (2) that \( \chi_r(W(s, t)) = t + 2(r - 1) \) whenever \( r \leq s \). We will also observe that we cannot have equality in (2) for large enough \( r \). We will also show that the fractional chromatic number of \( W(s, t) \) goes to infinity when \( t \) grows and \( s \) remains fixed. The paper concludes with some observations about the position of the graphs \( W(s, t) \) in the homomorphism order of graphs and with some open problems also mentioned on the way.

## 2 | PROOF OF THE MAIN RESULT

First we give the alternative definition of the graphs \( W(s, t) \) using the graph operation \( \Omega_k \) mentioned in Section 1. We put \( k = 2s - 1 \) and give the definition of only \( \Omega_{2s-1}(K_t) \) that we will use and refer to [26] for the construction of \( \Omega_k(G) \) in general.
**Definition 1.** The graph \( \Omega_{2s-1}(K_t) \) is defined as follows.

\[
V(\Omega_{2s-1}(K_t)) = \{(A_0, A_1, ..., A_{s-1}) : \forall i A_i \subseteq [t], |A_0| = 1, A_i \neq \emptyset, \forall i \in \{0, ..., s-3\} A_i \subseteq A_{i+2}, A_{i-2} \cap A_{s-1} = \emptyset\},
\]

\[
E(\Omega_{2s-1}(K_t)) = \{((A_0, A_1, ..., A_{s-1}), (B_0, B_1, ..., B_{s-1})) : \forall i \in \{0, 1, ..., s-2\} A_i \subseteq B_{i+1}, B_i \subseteq A_{i+1} \text{ and } A_{s-1} \cap B_{s-1} = \emptyset\}.
\]

Note that the above conditions also imply that \( A_i \cap A_{i-1} = \emptyset \) for all \( 1 \leq i \leq s-1 \) whenever \( (A_0, A_1, ..., A_{s-1}) \in V(\Omega_{2s-1}(K_t)) \).

It is straightforward and well known (see, e.g., [26,27]) that we have

\[
W(s, t) \cong \Omega_{2s-1}(K_t).
\]

Indeed, one can easily check that the following function \( g : V(W(s, t)) \to V(\Omega_{2s-1}(K_t)) \) provides an isomorphism between \( W(s, t) \) and \( \Omega_{2s-1}(K_t) \).

\[
g : (x_0, x_1) \mapsto (A_0, A_1, ..., A_{s-1}),
\]

where

\[
\forall i \in \{0, 1, ..., s-1\} : A_i = \{ j : x_j \leq i \text{ and } x_j \equiv i \mod 2 \}.
\]

**Remark 1.** We gave both descriptions of the graphs \( W(s, t) \), because we believe that both are useful. In particular, we will formulate the proof of Theorem 2 using the description of \( \Omega_{2s-1}(K_t) \) as we believe that it makes the presentation of the proof easier to follow. Nevertheless, when we were thinking about the proof we felt we could understand the structure of these graphs better by considering its vertices as the sequences given in its definition as \( W(s, t) \). (It is also remarked in [27] that it is the \( W(s, t) \) type description from which one easily sees that the number of vertices is \( t(s^{t-1} - (s-1)^{t-1}) \).)

Next we recall Tardif’s observation (2) that we state as a lemma for further reference and also prove it for the sake of completeness.

**Lemma 3** (Tardif [23]). For all positive integers \( r \) and \( s \)

\[
\chi_r(W(s,t)) \geq t + 2(r-1).
\]

**Proof.** We cannot have \( W(s, t) \to KG(t + h, r) \) for \( h < 2(r-1) \) as \( \chi(KG(t + h, r)) = t + h - 2r + 2 \) by the Lovász–Kneser theorem and this value is less than \( t = \chi(W(s, t)) \) whenever \( h < 2(r-1) \). \( \square \)

**Proof of Theorem 2.** We need to show

\[
\chi_s(W(s,t)) = \chi_s(\Omega_{2s-1}(K_t)) = t + 2(s-1).
\]
Lemma 3 already shows that the right-hand side is a lower bound thus our task is to prove the reverse inequality which is equivalent to the existence of a graph homomorphism from $W(s, t) \cong \Omega_{2s-1}(K_t)$ to $KG(t + 2(s - 1), s)$. Below we give such a homomorphism

$$f : (A_0, A_1, ..., A_{s-1}) \mapsto [z_0, ..., z_{s-1}],$$

where $[z_0, ..., z_{s-1}] \in \binom{[t+2(s-1)]}{s} = V(KG(t + 2(s - 1), s))$. We are going to give $z_i = f_i(U)$ below for $U = (A_0, A_1, ..., A_{s-1})$. (Note that we do not assume that the $z_i$'s are monotonically increasing with respect to their indices, we only need that all of them are distinct for a given $f(U) = [z_0, ..., z_{s-1}]$).

First assume that $s \geq 3$ is odd. (The $s = 1$ case is a trivial special case of Equation 1.)

For every even $i \in \{2, ..., s - 1\}$ we consider the three sets $A_{i-2}, A_{i-1}, A_i$ and for each such triple we define two elements of $f(U)$, namely, $f_{i-1}(U) = z_{i-1}$ and $f_i(U) = z_i$ as follows. According to the relative sizes of these three sets we will decide which ones of the elements $t + i - 1, t + i, (t + s - 1) + i - 1 = t + s + i - 2$, and $(t + s - 1) + i = t + s + i - 1$ will be put into the set $f(U)$. For every even $i$ we will either put two of these elements into $f(U)$ or if not then we will find enough elements from $[t]$ to compensate this hiatus. This will give us $s - 1$ distinct elements of $f(U)$. Finally we will define $f_0(U)$ as the missing $s$th element of $f(U)$. The rules are as follows.

(i) If $|A_{i-2}| > |A_{i-1}|$ then let $f_{i-1}(U) = t + i - 1$ and $f_i(U) = t + i$. If $|A_{i-1}| > |A_i|$, then let $f_{i-1}(U) = t + s + i - 2$ and $f_i(U) = t + s + i - 1$. (Note that since $A_{i-2} \subseteq A_i$, at most one of the above two inequalities can hold so our definition is meaningful.)

(ii) If $|A_{i-2}| < |A_{i-1}| < |A_i|$, then we must have $|A_i \setminus A_{i-2}| \geq 2$. In that case choose two distinct elements of $A_i \setminus A_{i-2}$ (these will be elements from $[t]$) to be $f_{i-1}(U)$ and $f_i(U)$.

(iii) If $|A_{i-2}| < |A_{i-1}| = |A_i|$, then $|A_i \setminus A_{i-2}| \geq 1$. Let $f_{i-1}(U)$ be an arbitrary element of $A_i \setminus A_{i-2}$ and let

$$f_i(U) = \begin{cases} t + s + i - 2 & \text{if min}(A_{i-1} \cup A_i) \in A_{i-1}, \\ t + s + i - 1 & \text{if min}(A_{i-1} \cup A_i) \in A_i. \end{cases}$$

Note that since $A_{i-1} \cap A_i = \emptyset$, $f_i(U)$ will be well defined.

(iv) If $|A_{i-2}| = |A_{i-1}| < |A_i|$, then let

$$f_{i-1}(U) = \begin{cases} t + i - 1 & \text{if min}(A_{i-2} \cup A_{i-1}) \in A_{i-2}, \\ t + i & \text{if min}(A_{i-2} \cup A_{i-1}) \in A_{i-1}. \end{cases}$$

Since $A_{i-2} \cap A_{i-1} = \emptyset$, $f_{i-1}(U)$ is well defined. Let $f_i(U)$ be an arbitrary element of $A_i \setminus A_{i-2}$. Such a choice is possible as $A_i \setminus A_{i-2} \neq \emptyset$ in this case.

(v) If $|A_{i-2}| = |A_{i-1}| = |A_i|$ (which means $A_i = A_{i-2}$) then let

$$\{f_{i-1}(U), f_i(U)\} = \begin{cases} \{t + i - 1, t + s + i - 1\} & \text{if min}(A_{i-1} \cup A_i) \in A_i, \\ \{t + i, t + s + i - 2\} & \text{if min}(A_{i-1} \cup A_i) \in A_{i-1}. \end{cases}$$
Note that since $A_i = A_{i-2}$, this formula is in accordance with the previous ones.

(vi) Finally, let $f_i(U)$ be equal to the unique $h \in A_0$.

Note that by the above we have defined $f_j(U)$ for every $0 \leq j \leq s - 1$ and if $j \neq j'$ then $f_j(U) \neq f_{j'}(U)$ thus we have $f(U) \in V(KG(t + 2(s - 1), s)$ as needed. We have to prove that $f$ is indeed a graph homomorphism from $W(s, t) \cong \Omega_{2s-1}(K_i)$ to $KG(t + 2(s - 1), s)$. We do this first and consider the case of even $s$ (that will be similar) afterwards.

Consider $U = (A_0, A_1, ..., A_{s-1})$ and $U' = (B_0, B_1, ..., B_{s-1})$. We have to show that if $f(U) \cap f(U') \neq \emptyset$, then $(U, U') \notin E(\Omega_{2s-1}(K_i))$.

Assume that $f(U) \cap f(U') \neq \emptyset$ and we have $h \in f(U) \cap f(U')$ for some $h \in [t]$. Then we have $h$ appearing in some $A_j$ and some $B_k$, where both $j$ and $k$ are even. In particular, $h \in A_{s-1} \cap B_{s-1}$, thus $A_{s-1} \cap B_{s-1} \neq \emptyset$, therefore $U$ and $U'$ cannot be adjacent.

Now assume that $f(U) \cap f(U') \neq \emptyset$ but the intersection is disjoint from $[t]$ thus we have $t + d \in f(U) \cap f(U')$ for some $1 \leq d \leq 2s - 2$.

If $d$ is odd and $d \leq s - 1$, then $d = i - 1$ for some even $2 \leq i \leq s - 1$, thus $t + d \in f(U)$ means $t + d = t + i - 1 = f_{i-1}(U)$. If this happens then either $|A_{i-2}| > |A_{i-1}|$ or $|A_{i-2}| = |A_{i-1}|$ and $\min(A_{i-2} \cup A_{i-1}) \in A_{i-2}$. Similarly, $t + d = t + i - 1 \in f(U')$ implies that either $|B_{i-2}| > |B_{i-1}|$ or $|B_{i-2}| = |B_{i-1}|$ and $\min(B_{i-2} \cup B_{i-1}) \in B_{i-2}$. Assume for contradiction that $(U, U')$ is an edge of our graph $\Omega_{2s-1}(K_i)$. Then we must have $A_{i-2} \subseteq B_{i-1}$ and $B_{i-2} \subseteq A_{i-1}$ implying

$$|A_{i-2}| \leq |B_{i-1}| \leq |B_{i-2}| \leq |A_{i-1}| \leq |A_{i-2}|,$$

therefore we must have equality everywhere. By $A_{i-2} \subseteq B_{i-1}$ and $B_{i-2} \subseteq A_{i-1}$ (that follows from $(U, U') \in E(\Omega_{2s-1}(K_i))$) this implies $A_{i-2} = B_{i-1}$ and $B_{i-2} = A_{i-1}$ and therefore $j := \min(A_{i-2} \cup A_{i-1}) = \min(B_{i-2} \cup B_{i-1})$. Our assumption on $d$ then implies both $j \in A_{i-2}$ and $j \in B_{i-2} = A_{i-1}$ which is impossible by $A_{i-2} \cap A_{i-1} = \emptyset$.

The situation is similar for the other possible values of $d$. If $d = i \leq s - 1$ is even, then $t + d = t + i \in f(U) \cap f(U')$ for some adjacent vertices $U, U'$ would again imply

$$|A_{i-2}| = |B_{i-1}| = |B_{i-2}| = |A_{i-1}|$$

and thus $A_{i-2} = B_{i-1}, B_{i-2} = A_{i-1}$ as above. Our assumption on $d$ now would imply for $j = \min(A_{i-2} \cup A_{i-1}) = \min(B_{i-2} \cup B_{i-1})$ that it must be both in $A_{i-1}$ and in $B_{i-1} = A_{i-2}$ leading to the same contradiction as in the previous paragraph.

For $s - 1 < d$ and $t + d \in f(U) \cap f(U')$ for adjacent vertices $U, U'$ we get a similar contradiction. In particular, this assumption implies $|A_{i-1}| \geq |A_i|$ and $|B_{i-1}| \geq |B_i|$ that by the adjacency of $U$ and $U'$ (meaning, in particular, $A_{i-1} \subseteq B_i$ and $B_{i-1} \subseteq A_i$) would imply

$$|A_{i-1}| = |B_i| = |B_{i-1}| = |A_i|$$

and thus $A_{i-1} = B_i$ and $B_{i-1} = A_i$. Then we obtain that $k := \min(A_{i-1} \cup A_i) = \min(B_i \cup B_{i-1})$ should belong (depending on the parity of $d$) to both $A_{i-1}$ and $B_{i-1} = A_i$ or to both $A_i$ and $B_i = A_{i-1}$ leading to the same contradiction that $A_{i-1} \cap A_i \neq \emptyset$. This finishes the proof for odd $s$.

Now assume that $s$ is even. We need only some minor modifications compared to the odd $s$ case. Let us now for every odd $i \in \{3, ..., s - 1\}$ define $f_{i-1}(U)$ and $f_i(U)$ almost the
same way as in points (i)–(v) above. (The only difference will be that the values $t + i - 1$ and $t + i$ are shifted by 1 to become $t + i$ and $t + i + 1$. In case of $s = 2$ the modified rules (i')–(v') will not apply, only those will that we denote by (vi') and (vii') below.) This gives the last $s - 2$ values of the set $f(U) = \{f_0(U), f_1(U), \ldots, f_{s-1}(U)\}$, what is left is to define $f_0(U)$ and $f_1(U)$ by a modified version of the sixth point above that has now two parts. The modified rules are as follows.

(i') If $|A_{i-2}| > |A_{i-1}|$ then let $f_{i-1}(U) = t + i$ and $f_i(U) = t + i + 1$. If $|A_{i-1}| > |A_i|$, then let $f_{i-1}(U) = t + s + i - 2$ and $f_i(U) = t + s + i - 1$.

(ii') and (iii') are identical to (ii) and (iii), respectively.

(iv') If $|A_{i-2}| = |A_{i-1}|$ then let $f_{i-1}(U) = \{t + i, t + s + i - 1\}$ if $\min(A_{i-1} \cup A_i) \in A_i$,

\[
\{t + i + 1, t + s + i - 2\}\] if $\min(A_{i-1} \cup A_i) \in A_{i-1}.
\]

Let $f_i(U)$ be an arbitrary element of $A_i \setminus A_{i-2}$.

(v') If $|A_{i-2}| = |A_{i-1}| = |A_i|$ then let

\[
\{f_{i-1}(U), f_i(U)\} = \{t + i + 1, t + s + i - 2\}\] if $\min(A_{i-1} \cup A_i) \in A_{i-1}.
\]

Note again that since $A_i = A_{i-2}$, this formula is in accordance with the ones in cases (iii') and (iv').

(vi') If $|A_i| = |A_0|$, then let

\[
f_0(U) = \begin{cases} t + 1 & \text{if } \min(A_0 \cup A_i) \in A_0, \\ t + 2 & \text{if } \min(A_0 \cup A_i) \in A_i. \end{cases}
\]

Note that in this case both $A_0$ and $A_i$ contain only one element and the value of $f_0(U)$ is $t + 1$ or $t + 2$ depending on which one of the two is smaller. At the same time let

\[
f_i(U) = h, \quad \text{where } A_i = \{h\},
\]

that is, $h \in [t]$ is the unique element of $A_i$.

(vii') If $|A_i| > |A_0|$, then since $|A_0| = 1$ we have $|A_i| \geq 2$. Now choose two arbitrary distinct elements of $A_i$ for $f_0(U)$ and $f_i(U)$.

Note that we have $|A_i| \geq 1 = |A_0|$ by the definition of $\Omega_{2s-1}(K_t)$, so we do not have to consider the possibility that $|A_0| > |A_i|$, it never occurs.

With this definition of $f(U)$ the proof that $f$ is a graph homomorphism is essentially identical to that we presented in the odd $s$ case. The main difference is that now those $j \in [t]$ that appear as elements of the sets $f(U)$ are all elements of some $A_i$ where $i$ is odd, while the corresponding $i$'s were all even in the case of odd $s$. The rest of the arguments work the same way as in the case of odd $s$.

This completes the proof. □
We remark that by the composition of homomorphisms Theorem 2 determines the s-fold chromatic number of every s-wide colorable t-chromatic graph.

3 | ON OTHER MULTICHROMATIC NUMBERS OF \( W(s, t) \)

An immediate consequence of Theorem 2 is that we can give the multichromatic numbers \( \chi_r(W(s, t)) \) for all \( r \leq s \).

**Corollary 4.** If \( r \leq s \), then
\[
\chi_r(W(s, t)) = t + 2(r - 1).
\]

The proof follows from the following simple lemma (which is essentially Lemma 2.3(iv) of [26]) combined with Tardif's observation given in Lemma 3.

**Lemma 5** (Wrochna [26]). For all \( 1 \leq r \leq s \) we have
\[
W(s, t) \to W(r, t).
\]

**Proof.** Define the following function for all \( 0 \leq a \leq s \).
\[
\varphi(a) = \begin{cases} 
a & \text{if } 0 \leq a \leq r, \\
r & \text{if } r < a \leq s. 
\end{cases}
\]

It is straightforward to check that the mapping \( g : (x_1 \ldots x_t) \mapsto (\varphi(x_1) \ldots \varphi(x_t)) \) is a homomorphism from \( W(s, t) \) to \( W(r, t) \) for all \( 1 \leq r \leq s \).

**Proof of Corollary 4.** In view of Lemma 3 it is enough to prove that \( \chi_r(W(s, t)) \) is at most the claimed value if \( r \leq s \). Applying Lemma 5 and Theorem 2 to \( r \leq s \) we have
\[
W(s, t) \to W(r, t) \to KG(t + 2(r - 1), r)
\]

implying
\[
\chi_r(W(s, t)) \leq t + 2(r - 1)
\]
as needed.

For \( r > s \) we do not know the value of \( \chi_r(W(s, t)) \). We know from Lemma 3 though that \( \chi_r(W(s, t)) \geq t + 2(r - 1) \) so as a very first problem the question arises whether we could have equality here for every \( r \). The proposition below, which was also noted by Claude Tardif [24], shows that this is not the case.
Proposition 6. For all pairs of positive integers \( t \geq 3 \) and \( s \geq 1 \) there exists some threshold \( r_0 = r_0(s, t) > s \) for which

\[
\chi_r(W(s, t)) > t + 2(r - 1) \tag{3}
\]

whenever \( r \geq r_0. \)

Proof. Assume for the sake of contradiction that for some fixed \( s \) and \( t \) we have \( \chi_r(W(s, t)) = t + 2(r - 1) \) for arbitrarily large \( r \). That would imply that \( \chi_r(W(s, t)) \leq \lim_{r \to \infty} \frac{t + 2(r - 1)}{r} = 2. \) However, this cannot be true since \( W(s, t) \) is not bipartite for \( t \geq 3 \) and thus it contains an odd cycle \( C_{2b+1} \) for some positive integer \( b \). Thus we must have \( \chi_r(W(s, t)) \geq \chi_f(C_{2b+1}) = \frac{2b+1}{b} \), a number larger than 2 with the constant value \( \frac{1}{b} \). \( \square \)

Remark 2. It is worth noting, as an anonymous referee did, that the above proof also implies that no general upper bound on \( \chi_r(W(s, t)) \) of the form \( \chi_r(W(s, t)) \leq t + 2(r - 1) + q(s, t) \) can be valid for all \( r \), where \( q(s, t) \) is any function depending only on \( s \) and \( t \). So any nontrivial upper bound on \( \chi_r(W(s, t)) \) would be interesting. (We know that asymptotically \( \chi_r(W(s, t)) \approx r_0f(W(s, t)) \). In Theorem 7 we will see that \( \chi_f(W(s, t)) \) goes to infinity with \( t \) for any fixed \( s \).) A more modest-looking problem than giving strong upper bounds on \( \chi_r(W(s, t)) \) seems to be just trying to bound the best threshold \( r_0(s, t) \) for which Proposition 6 holds. As the already mentioned anonymous referee pointed out we have \( r_0 \leq (3s - 2)(t - 2) \) as a consequence of the fact \( \chi_f(W(s, t)) \geq 2 + \frac{1}{3s - 2} \) that we will see below. At the same time the lower bound \( r_0(s, t) \geq s + 1 \) that follows from Theorem 2 is independent of \( t \). It is frustrating that we were not able to decide whether this lower bound is sharp although the proof of Theorem 2 might suggest this. As this discussion shows even that would be interesting to know whether the optimal value of \( r_0(s, t) \) should depend on both \( s \) and \( t \) or perhaps only on \( s \).

Remark 3. The proof of Proposition 6 does not specify \( b \) as its value is not essential there. Nevertheless one can easily see that \( W(s, 3) \cong C_{6s-3} \). It is also easy to see that \( g_0(W(s, t)) \), the odd girth of \( W(s, t) \) must be at least \( 2s + 1 \) and we have equality here for \( t \geq 2s + 1 \) since a cycle \( C_{2s+1} \) is formed in \( W(s, 2s + 1) \) by the vertices given by the sequence \( 0, 1, 2, ..., s, s, s - 1, ..., 2, 1 \) and its cyclic permutations. (For larger \( t \) these sequences can be extended by an arbitrary number of coordinates equal to \( s \).) As one of the referees noted \( g_0(W(s, t)) = 2s + 1 \) for \( t \geq 2s + 1 \) is also immediately implied by Proposition 1 and the fact that \( C_{2s+1} \) admits an \( s \)-wide coloring with at most \( t \) colors. We also note that the unpublished paper by Baum and Stiebitz [1] gives the general formula \( 2s - 1 + 2\left\lfloor \frac{2s-1}{t-2} \right\rfloor \) for the odd girth of \( W(s, t) \).

The previous discussion raises the question what we can say about the fractional chromatic number of the graphs \( W(s, t) \). As a consequence of Theorem 2 we know \( \chi_f(W(s, t)) \leq \frac{t + 2(s - 1)}{s} \) and the relation \( W(s, t) \supseteq W(s, 3) \cong C_{6s-3} \) implies that it is at least \( 2 + \frac{1}{3s - 2} \) for \( t \geq 3 \).
Unfortunately we were not able to prove matching lower and upper bounds. But we can at least show that for any fixed \( s \) the fractional chromatic number of \( W(s, t) \) gets arbitrarily large as \( t \) tends to infinity.

**Theorem 7.** For any fixed positive integer \( s \) we have

\[
\lim_{t \to \infty} \chi_f(W(s, t)) = \infty.
\]

The proof will be a simple consequence of the (already known) fact that certain generalized Mycielski graphs admit \( s \)-wide colorings. To give more details we introduce generalized Mycielski graphs below.

**Definition 2.** The \( h \)-level generalized Mycielskian \( M_h(G) \) of a graph \( G \) is defined as follows.

\[
V(M_h(G)) = \{(v, j) : v \in V(G), 0 \leq j \leq h - 1\} \cup \{z\}.
\]

\[
E(M_h(G)) = \{((u, i), (v, j)) : uv \in E(G) \text{ and } |i - j| = 1 \text{ or } i = j = 0\}
\]

\[
\cup \{z, (v, (h - 1))\}.
\]

The \( d \) times iterated \( h \)-level generalized Mycielskian \( M_h(M_h(\ldots M_h(G)\ldots)) \) of a graph \( G \) will be denoted by \( M_h^{(d)}(G) \).

The term Mycielskian of a graph \( G \) usually refers to \( M(G) = M_2(G) \) and Mycielski graphs are the iterated Mycielskians of \( K_2 \) introduced by Mycielski [13] as triangle-free graphs whose chromatic number grows by 1 at every iteration. The property \( \chi(M(G)) = \chi(G) + 1 \) is well known to hold for any \( G \) but the analogous equality is not always true for \( h \)-level Mycielskians if \( h > 2 \), cf. Tardif [20]. Nevertheless Stiebitz [19] showed that \( \chi(M_h(G)) = \chi(G) + 1 \) is also true if \( G \) is a complete graph or an odd cycle. (More generally one can say that this is the case whenever \( G \) is a graph for which the topological lower bound on the chromatic number by Lovász [10] is sharp, cf. [5,12,19] or [17] for more details.) So by Stiebitz’s result we have

\[
\chi(M_h^{(d)}(K_2)) = d + 2
\]

for all positive integers \( d \) and \( h \).

The \( t \)-chromaticity of \( W(s, t) \) is proved in [1,5,17] by showing the existence of \( t \)-chromatic graphs that admit a homomorphism into \( W(s, t) \). In case of [1,5] these are generalized Mycielski graphs \( M_{h}^{(t-2)}(K_2) \) for appropriately large \( h \). We use the existence of this homomorphism also for the proof of Theorem 7. (Since [1] is unpublished and [5] gives this explicitly only for \( s = 2 \), we give some more details for the sake of completeness. Nevertheless, this is a straightforward generalization of the construction given in [5] as already noted in [17] where the case \( s = 3 \) is made explicit. So the following is a straightforward extension of Lemma 4.3 from [17] also attributed to [5] there.)
Lemma 8 (Gyárfás et al. [5]). If \( G \) has an \( s \)-wide coloring with \( t \) colors, then \( M_{3s-2}(G) \) has an \( s \)-wide coloring with \( t + 1 \) colors.

**Proof.** Fix an \( s \)-wide coloring \( c_0 : V(G) \to [t] \) of \( G \). Let \( c : V(M_{3s-2}(G)) \to [t] \cup \{ \gamma \} \) be the following coloring using the additional color \( \gamma \). Set \( c(z) = \gamma \) and

\[
c((v, j)) = \begin{cases} 
\gamma & \text{if } j \in \{s, s + 2, \ldots, 3s - 4\}, \\
c_0(v) & \text{otherwise}.
\end{cases}
\]

If we have a walk of odd length between vertices \((u, i)\) and \((v, j)\) with \( c(u, i) = c(v, j) \in [t] \) that walk must either traverse the vertex \( z \) or use an edge of the form \( \{(a, 0), (b, 0)\} \). In the latter case we can assume that the walk does not go through \( z \) and then it projects down to a walk of the same length between \( u \) and \( v \) in \( G \) with \( c_0(u) = c_0(v) \) so its length must be at least \( 2s + 1 \) by \( c_0 \) being \( s \)-wide. In case the walk traverses \( z \) we can assume that we have \( i \neq j \mod 2 \) and thus without loss of generality \( j \equiv s \mod 2 \) implying that \( j \leq s - 2 \). But then the distance between \((v, j)\) and \( z \) is already at least \( 2s \), so the length of our walk is at least \( 2s + 1 \).

Since deleting the set of vertices \( \{(v, 0)\}_{v \in V(G)} \) from \( M_{3s-2}(G) \) the remaining induced subgraph is bipartite and \( \gamma \) appears only on one side of this bipartite graph, any odd length walk between two vertices colored \( \gamma \) must use an edge of the form \( \{(u, 0), (v, 0)\} \). But the distance of any \( \gamma \)-colored vertex from such vertices is at least \( s \), so such a walk also cannot be shorter than \( 2s + 1 \). Thus \( c \) is indeed an \( s \)-wide coloring. \( \square \)

For \( M(G) = M_2(G) \) Larsen, Propp, and Ullman [9] made the very nice observation that \( \chi_f(M(G)) \) can be given by a simple function of \( \chi_f(G) \), namely,

\[
\chi_f(M(G)) = \chi_f(G) + \frac{1}{\chi_f(G)}.
\]

This was later generalized by Tardif for generalized Mycielskians.

**Theorem 9** (Tardif [20]).

\[
\chi_f(M_h(G)) = \chi_f(G) + \frac{1}{\sum_{i=0}^{h-1} (\chi_f(G) - 1)^i}.
\]

Note that for non-bipartite graphs Tardif’s theorem gives

\[
\chi_f(M_h(G)) = \chi_f(G) + \frac{\chi_f(G) - 2}{(\chi_f(G) - 1)^h - 1}
\]

and also that it implies that \( \chi_f(M_h^{(d)}(G)) \) tends to infinity as \( d \) goes to infinity for any fixed finite \( h \).
Proof of Theorem 7. The proof is already immediate by the foregoing. Lemma 8 and Tardif’s Theorem 9 together imply that

\[ \chi_f(W(s, t + 1)) \geq \chi_f(M_{3s-2}(W(s, t))) = \chi_f(W(s, t)) + \frac{1}{\sum_{i=0}^{3s-3}(\chi_f(W(s, t)) - 1)^i}, \]

and this implies the statement.

In view of Lemma 8 it may be interesting to note that while a generalized Mycielskian of \( W(s, t) \) admits a homomorphism into \( W(s, t + 1) \), the latter also admits a (very natural) homomorphism into another generalized Mycielskian of \( W(s, t) \).

**Proposition 10.**

\[ W(s, t + 1) \rightarrow M_s(W(s, t)). \]

**Proof.** We explicitly give the homomorphism. Let

\[ g((x_1 \ldots x_t)) = \begin{cases} (x_1 \ldots x_{t+1}, s-x_{t+1}) & \text{if } x_{t+1} > 0 \text{ and } (x_1 \ldots x_{t}) \in V(W(s, t)), \\ (01 \ldots 1, s-1) & \text{if } \{i : x_i = 1\} = \{t+1\}, \\ 0 & \text{if } x_{t+1} = 0. \end{cases} \]

(In fact, in the second case \((01 \ldots 1, s-1)\) can be substituted by an arbitrarily chosen \((y_1 \ldots y_t, s-1)\) for which \((y_1 \ldots y_t) \in V(W(s, t)).\)

It is straightforward to check that the given function is indeed a graph homomorphism. □

Thus we obtained that in the homomorphism order of graphs (cf. [7]) in which \( F \leq G \) if and only if \( F \rightarrow G \) we have \( W(s, t + 1) \) sandwiched between two different generalized Mycielskians of \( W(s, t) \), in particular,

\[ M_{3s-2}(W(s, t)) \leq W(s, t + 1) \leq M_s(W(s, t)). \quad (4) \]

This excludes the possibility that our upper bound \( t + \frac{2(s-1)}{s} \) on \( \chi_f(W(s, t)) \) provided by Theorem 2 would be tight at least for all sufficiently large \( t \), because then the difference \( \chi_f(W(s, t + 1)) - \chi_f(W(s, t)) \) would be equal to \( \frac{1}{s} \) for large \( t \) contradicting Tardif’s Theorem 9. Note that (4) implies

\[ \chi_f(W(s, t)) + \frac{\chi_f(W(s, t)) - 2}{(\chi_f(W(s, t)) - 1)^{3s-2} - 1} \leq \chi_f(W(s, t + 1)) \]

\[ \leq \chi_f(W(s, t)) + \frac{\chi_f(W(s, t)) - 2}{(\chi_f(W(s, t)) - 1)^s - 1}. \]
With a little more considerations we can also show that \( W(s, t + 1) \) is actually \textit{strictly} sandwiched between the above two generalized Mycielskians of \( W(s, t) \) if \( s > 1 \) and \( t > 2 \).

\[\text{Remark 4.} \quad \text{There is a remark in [17] that seemingly contradicts to what we claim here. Namely, in Remark 9 of [17] it is written that behind the coloring given in a previous proof there “is the recognition of a homomorphism from } W(s, t) \text{ to } M_{3s-2}(W(s, t-1)).” This was not accurate. Although the proof and the coloring that remark refers to is correct, the said homomorphism does not exist in general. It does, however, if we change } 3s - 2 \text{ to } s \text{ as we have seen in Proposition 10.}\]

**Proposition 11.** If \( s \geq 2, t \geq 3 \) then

\[M_{3s-2}(W(s, t)) < W(s, t + 1) < M_s(W(s, t)).\] (5)

For \( s = 1 \) all three graphs are isomorphic to \( K_{t+1} \). For \( s > 1, t = 2 \) we have

\[M_{3s-2}(W(s, 2)) \cong C_{6s-3} \cong W(s, 3) < M_s(W(s, 2)) \cong C_{2s+1}.\]

\[\text{Proof.}\] It is well known and easy to prove that if \( G \) is a vertex-color-critical graph (i.e., one from which deleting any vertex its chromatic number decreases) and \( \chi(M_h(G)) = \chi(G) + 1 \), then \( M_h(G) \) is also vertex-color-critical (see this, e.g., as Problem 9.18 in the book [11] for \( h = 2 \)). It is shown independently both in [1] and [17] that \( W(s, t) \) is edge-color-critical for every \( s \geq 1, t \geq 2 \). Thus all three graphs appearing in (5) are vertex-color-critical. Since they all have the same chromatic number this implies that any homomorphism that exists between any two of them should be onto. This also means that if any two of them would be homomorphically equivalent, then those two should have the same number of vertices, in particular, any homomorphism between them is a one-to-one mapping between their vertex sets. This is clearly not the case for the homomorphism given in the proof of Proposition 10 since several distinct vertices (their exact number is \( s' \) (1) are mapped to the vertex \( z \) unless \( s = 1 \).

If a homomorphism between \( M_{3s-2}(W(s, t)) \) and \( W(s, t + 1) \) was one-to-one then by the edge-color-criticality of \( W(s, t + 1) \) it cannot happen that we map two nonadjacent vertices of \( M_{3s-2}(W(s, t)) \) to two adjacent ones of \( W(s, t + 1) \), since then deleting the latter adjacency we would still have a homomorphism but into a graph of smaller chromatic number. Thus such a homomorphism would then be an isomorphism, that is, the two graphs would be isomorphic which is clearly not the case if \( s > 1 \) and \( t > 2 \). (A quick way to see this is the following. The maximum degree of \( W(s, t + 1) \) is \( t(t^{s-1} - (s - 1)(t^{s-1}) \) that cannot be a power of 2 for \( s > 1 \) unless \( t = 2 \).) The remaining cases in the statement are straightforward to check.

Finally, we collect here some of the open problems mentioned in this last section.

1. Determine the value of \( \chi_r(W(s, t)) \) for \( r > s \) or give at least nontrivial bounds on it.
2. Determine or bound the value of \( \chi_t(W(s, t)) \).
3. Give better estimates on the optimal value of \( r_0(s, t) \), the threshold in Proposition 6. What we know so far is only \( s + 1 \leq r_0(s, t) \leq (3s - 2)(t - 2) \) (cf. Remark 2). In particular, as a
remark of an anonymous referee suggested: Decide whether this value should depend on both $s$ and $t$.

ACKNOWLEDGMENTS
We thank Claude Tardif for sharing with us already an early version of his paper [23] which contained his interesting question that became the starting point of our work presented here. This study was partially supported by the National Research, Development and Innovation Office (NKFIH) grants K-120706 and BME NC TKP2020 and also by the BME-Artificial Intelligence FIKP grant of EMMI (BME FIKP-MI/SC). The work of Gábor Simonyi was also partially supported by the grants K-132696 and SNN-135643 of NKFIH Hungary.
