Pharmacokinetics of traditional Chinese syndrome and recipe: a hypothesis and its verification (I)

Xi Huang1, Ping Ren1, Ai Dong Wen2, Li Li Wang1, Li Zhang1 and Feng Gao3

Abstract

AIM To propose a hypothesis defining the absorption, distribution, metabolism and elimination of traditional Chinese recipe (TCR) component in blood of healthy subjects and patients, and estimate its correctness.

METHODS The pharmacokinetics (PK) of same dose of drug was studied in the animal model of traditional Chinese syndrome (S) and healthy animals. The classification, terminology, concept and significance of the hypothesis were set forth with evidence provided in the present study. The hypotheses consisted of traditional Chinese syndrome PK (S-PK) and traditional Chinese recipe PK (R-PK). Firstly, the observed tetramethylpyrazine (TMP) PK in healthy, chronically reserpinized rats (rat model of spleen deficiency syndrome, RMSDS) and RMSDS treated with Sijunzi decoction (SJDZ) for confirmation were used to verify S-PK; secondly, the ferulic acid (FA) PK in healthy and high molecular weight dextran (HMWD)-induced rabbit model with blood stasis syndrome (RDBSS) was also used to verify S-PK; and lastly, TMP PK parameters in serum of healthy rats after orally taken -Ligusticum wallichii (LW), LW and Salvia miltiorrhiza (LW&SM) decoctions were compared to verify R-PK.

RESULTS The apparent first-order absorption \( [K_a, (13.61 \pm 2.56)h^{-1}] \), area under the blood drug concentration-time curve \( [AUC, (24.88 \pm 9.76) \mu g\cdot h^{-1}\cdot mL^{-1}] \), maximum drug concentration \( [C_{max}, (4.82 \pm 1.23) \mu g\cdot mL^{-1}] \) of serum TMP in RMSDS were increased markedly \((P<0.05)\) compared with those \( [K_a = (5.41 \pm 1.91)h^{-1}, AUC = (5.20 \pm 2.57) \mu g\cdot h^{-1}\cdot mL^{-1}, C_{max} = (2.33 \pm 1.77) \mu g\cdot mL^{-1}] \) of healthy rats (HR). The apparent first-order rate constant for \( \alpha \) and \( \beta \) distribution phase \( [\alpha = (0.38 \pm 0.09)h^{-1}, \beta = (0.06 \pm 0.03)h^{-1}] \), the apparent first-order intercom partmental transfer rate constants \( [K_{10} = (0.24 \pm 0.07)h^{-1}, K_{12} = (0.11 \pm 0.02)h^{-1}, K_{21} = (0.11 \pm 0.02)h^{-1}] \) of serum TMP in RMSDS were decreased significantly \((P<0.01)\) compared with those \( [K_{10} = (0.88 \pm 0.20)h^{-1}, K_{12} = (1.45 \pm 0.47)h^{-1}, K_{21} = (0.72 \pm 0.22)h^{-1}] \) of HR. However, no apparent differences occurred between HR and RMSDS treated with SJJDZ. The serum FA concentration and its AUC \( [5.6690 \pm 2.3541] \mu g\cdot h^{-1}\cdot mL^{-1}] \) in RMBSS were also higher than those \( [AUC = (2.7566 \pm 0.26)g\cdot mL^{-1}] \) of healthy rabbits \((P<0.05)\). The \( K_a = (11.51 \pm 2.82)h^{-1}, AUC = (0.84 \pm 0.017) \mu g\cdot h^{-1}\cdot mL^{-1} \) of LW & SM-derived TMP in serum were much lower \((P<0.05)\) than those \( [K_a = (19.58 \pm 4.14)h^{-1}, AUC = (1.27 \pm 0.26) \mu g\cdot h^{-1}\cdot mL^{-1}] \) of LW-derived TMP in serum after oral decoctions.

CONCLUSION The SDS and blood stasis syndrome state could affect significantly the pharmacokinetic parameters of drugs and the abnormal SDS pharmacokinetic parameters could be normalized by SJJDZ. The combination of Chinese medicine in TCR could reciprocally affect the pharmacokinetic parameters of other components absorbed into the systemic circulation. These results support the S and R-PK hypothesis.
INTRODUCTION

Three progresses in the related subjects arouse us to propose hypotheses defining the traditional Chinese syndrome (S) and recipe PK (S-PK and R-PK)\(^\text{[1-6]}\). Firstly, in the field of traditional Chinese medicine (TCM), their characteristic PK has not developed as a consequence of what are the chemical components absorbed into the circulation after administering traditional Chinese recipe (TCR) is not clear yet. Then, the progresses in successful detection of TCR-derived component in serum from 1985 to 1989 supported the concept of above hypothesis\(^\text{[7,8]}\). Finally, the theoretical and practical achievements of chronopharmacokinetics are not only an example but also enhanced our intention of presenting the hypothesis\(^\text{[9-11]}\).

The investigation of TCR-derived compound in vivo affords a sound basis for advancing the hypothesis of S and R-PK\(^\text{[2-8,12,13]}\) and the inspiration from the theory and practice of chronopharmacokinetics greatly encourages\(^\text{[9-11]}\). The knowledge dealing with the rhythmic changes of pharmacokinetic phenomenon in living organisms is called chronopharmacokinetics\(^\text{[14]}\), in which, PK of administering drug at different time is not constant and is related to its therapeutic and toxic effects\(^\text{[14]}\). Similarly, are there possible differences of serum drug concentration and its pharmacokinetic parameters between different TCS and different Chinese medicines of TCR? In other words, does TCS state affects a consequence of what are the chemical components absorbed into the circulation after administering traditional Chinese recipe (TCR) is not clear yet. Then, the progresses in successful detection of TCR-derived component in serum from 1985 to 1989 supported the concept of above hypothesis\(^\text{[7,8]}\). Finally, the theoretical and practical achievements of chronopharmacokinetics are not only an example but also enhanced our intention of presenting the hypothesis\(^\text{[9-11]}\).

The verification of S-PK

The preparation of SJZD (TCR): it consists of Panax ginseng C.A.Mey, Atractylodes macrocephala Koidz, Poria cocos (Schw.) Wolf, Glycyrrhiza uralensis Fisch were purchased from Xi’an Pharmaceutical Company (Xi’an, China). All organic reagents were bought from Xi’an Chemical Reagent Factory. All chemicals were of analytical reagent grade unless otherwise stated. Methaqualonum (internal standard) was presented by Institute of Materia Medica, Beijing Medical University (Beijing, China). Coumarin (internal standard) was purchased from Sigma. High molecular weight dextran (HMWD) (M,500 000) was bought from Tianjin Air Force hospital (Tianjin, China).

Instruments

The following main instruments were used in the experiment: Shimadzu LC-6A HPLC system; SPD-6A ultraviolet detector; shimadzu QP-1000 gas chromatography-mass spectrometer. 7650 infrared spectrometer. RH-90 NMR meter.

Definitions of S and R-PK hypotheses\(^\text{[1-6]}\)

The S-PK hypothesis indicates that the pharmacokinetic differences between the different TCS have statistical significance and R-PK hypothesis means that one of TCM could influence markedly the pharmacokinetic parameters of other TCM-derived components in blood when administered together in same TCR. The above two pharmacokinetic characteristics are related to the therapeutic, toxic responses and theory of TCM.

MATERIALS AND METHODS

Drugs, chemicals and reagents

Tetramethylpyrazine phosphate (TMPP) intravenous infusion in 2 ml ampule (25 g/L, lot No. 90101) and sodium ferulate (SF) were purchased from Guangdong Limin Pharmaceutical Factory (Shaoguang, China); reserpine injection solution in 1 mL (1mg, lot No. 901008) was purchased from Red-Flag Pharmaceutical Factory of Shanghai Medical University (Shanghai, China).

LW was purchased from Dujiangyan City Pharmaceutical Company (Sichuan, China) which was identified by Professor Hu ZH (the Department of Botany, Northwest University, Xi’an, China), Salvia miltiorrhiza (SM), Panax ginseng C.A.Mey,

Atractylodes macrocephala Koidz, Poria cocos (Schw.) Wolf, Glycyrrhiza uralensis Fisch were purchased from Xi’an Pharmaceutical Company (Xi’an, China). All organic reagents were bought from Xi’an Chemical Reagent Factory. All chemicals were of analytical reagent grade unless otherwise stated. Methaqualonum (internal standard) was presented by Institute of Materia Medica, Beijing Medical University (Beijing, China). Coumarin (internal standard) was purchased from Sigma. High molecular weight dextran (HMWD) (M,500 000) was bought from Tianjin Air Force hospital (Tianjin, China).
saline (0.1 mL·kg⁻¹·d⁻¹, 14 d). Group 2 (RMSDS, \(n = 72\)): healthy Wistar rats were injected ip with reserpine (0.5 mg·kg⁻¹·d⁻¹, 14d). Group 3 (RMSDS treated by SJZD, \(n = 72\)): healthy Wistar rats were prepared the same as Group 2 and treated with intragastric admi nistration of SJZD (30 g·kg⁻¹, d⁻¹, 14 d). The above three groups were given po 10 mg·kg⁻¹·day⁻¹ of TMPP 24 h after the final injection of normal saline or reserpine. Group 4 (HR-2, \(n = 6\)): healthy male New Zealand white rabbits afforded from the Animal Center of our university were injected intravenously with normal saline (15 mL·kg⁻¹). Group 5 (RMBS, \(n = 6\)): rabbits were injected by intravenous injection of 100 g/L HMWD in normal saline (15 mL·kg⁻¹). FA was injected in travenously of 5 mg·kg⁻¹ 30 min after the end of injection of normal saline or HMWD. Rats and rabbits were fasted 12 h before administration.

The 0.5 mL of serum samples of rats were obtained by decapitation after a single oral TMPP at 0.083 h, 0.5 h, 1.0 h, 3 h, 5 h, 8 h, 12 h and 24 h, respectively. At each time point, 6 samples were obtained. The rabbit blood sample of 0.5 mL was directly withdrawn and collected from the ear vein at 2 min, 5 min, 10 min, 20 min, 30 min, 45 min, 60 min, 90 min, 120 min, 150 min and 180 min after intravenous FA. The blood samples were centrifuged (3000 r·min⁻¹, 5 min), and 0.2 mL of the resulting serum was used.

**Chromatographic condition**

Determination of serum TMP concentration[15-17]: the chromatographic system (Shimadzu LC-6A, Japan) consisted of two pumps (LC-6A), a sample injector (Rheodyne, model 7125), a SPD-6AV detector (Shimadzu) and a C-R3A data processor (Shimadzu). A Shim-Pach CLC-ODS column (particles 5 µm, 150 mm × 4.6 mm ID) was used for quantitative analysis; AUFs was 0.04, the flow rate was 1 mL/min, the paper speed was 3 mm/min, the column temperature was 38°C, the detection wavelength was 280 nm, the mobile phase consisted of methanol and water (72:28 v/v). The serum concentration data of HR-1 and RMSDS were analyzed by the SP87 (Chinese Pharmacological Association) software.

Determination of serum FA concentration[18]: the detector was set at 320 nm (AUFs: 0.01); the mobile phase was acetonitrile 0.1 mL·min⁻¹ phosphoric acid (pH 2.5) (3:7, v/v); the other chromatographic conditions were the same as those in determining serum TMP concentration.

**Sample preparation**

Serum sample contained TMP: internal standard of Methaqualonum (428 ng) was added to 5 mL of ground conical centrifuge tube containing 100 µL of methanol. The mixture was oscillated on vortex mixer and evaporated to dryness at 48°C on water bath under the stream of nitrogen. Successively added 0.2 mL of blank rat serum, the different amount of TMP (0.044 µg·mL⁻¹, 0.087 µg·mL⁻¹, 0.168 µg·mL⁻¹, 0.336 µg·mL⁻¹, 0.671 µg·mL⁻¹ and 1.342 µg·mL⁻¹), 0.2 mL 0.05 mol/L of NaOH solution and 2 mL of trichloromethane to the above centrifuge. After the mixture was vortex mixed again for 15 s, it was centrifuged at 3000 r·min⁻¹ for 10 min. The organic layer was transferred into another 5 mL ground conical centrifuge tube contained 100 µL of 1mol/L hydrochloric acid-methanol solution (50 mL/L) and evaporated again to dryness on water bath at 48°C under a stream of nitrogen. The residue was dissolved with 100 µL of methanol solution and then 20 µL was determined by HPLC each time[15].

Serum sample contained FA: to 0.2 mL of rabbit serum added 0.4 mL of acetonitrile contained 1.5 µg of coumarin internal stand ard. The mixture was vortex mixed and then the deproteinated precipitate was sep arated by centrifugation (3000 r·min⁻¹, 5 min). The supernatant was evaporated at 60°C water bath under a stream of nitrogen. The residue was dissolved in 60 µL acetonitrile and 20 µL of solution was directly injected into HPLC system for determination. To each 0.2 mL of rabbit blank sera 20 to 800 µg·L⁻¹ of FA were added respectively. Their serum samples were analyzed separately by the corresponding method described above[18].

**The verification of R-PK**

The preparation of LW decoction, LW&SM (LW: SM=3:1) decoction: the dried roots of them were pounded to about 2 mm × 4 mm × 4mm pieces. The other procedure was the same as those for preparing SJZD. The final concentration of LW decoction and LW&SM decoction were 3 g·mL⁻¹ and 4 g·mL⁻¹, respectively. TMP content of LW decoction and LW&SM decoctions were determined before administration[17].

Only healthy rats were used to verify R-PK. Twelve Wistar rats were divided into two groups. LW decoction (30 g·kg⁻¹) was given intragastrically to one group (\(n = 6\)) and LW&SM decoction (40 g·kg⁻¹) was given to another group (\(n = 6\)). The blood samples of 0.2 mL each were obtained by cutting the animal tails at 0.083 h, 0.25 h, 0.50 h, 0.75 h, 1.00 h, 1.50 h, 2.00 h, 3.00 h and 5.00 h after oral TCR.

Analytical method: all quantitative but qualitative detections of TMP were the same as those described above. Chromatographic
conditions: Shim-Pach CLC-ODS column (particles 5 µm, 150 mm × 4.6 mm ID) was also used for quantitative analysis; the half-preparative column (particles 10 µm, 250 mm × 10 mm ID) was used for the separation and purification of LW decoction components in serum; Nebulizer and vaporizer temperatures were 250 ºC. The drift voltage was 70eV.

The identification of LW-derived component in serum\(^\text{[17]}\): the related component was firstly separated, purified, enriched and then identified by 3-dimensional HPLC, mass spectrum, and NMR. Calibration curve and statistical analysis were the same as the correspondings described above.

**Statistical analysis**

The results are expressed as \( \overline{x} \pm s \). Comparison of serum drug concentration and pharmacokinetic parameters between controls and studied model of LW and LW&SM decoctions were made by \( t \) test for paired samples. Differences were considered significant when \( P < 0.05 \).

**RESULTS**

The methodological results

One of the chemical components in serum after oral administration of LW extract to rats was identified as TMP by three-dimensional HPLC, UV, IR, MS and NMR (data not shown)\(^\text{[17]}\).

The chromatographic retention time of TMP, methaqualone (internal standard), FA and coumarin (internal standard) were 3.992 min, 6.223 min, 3.82 min and 7.68 min, respectively (Figure 1, A-B)\(^\text{[17,18]}\). They were separated well under their own chromatographic conditions. The ratios between the peak areas of the TMP and methaqualon (internal standard) in serum of rat, and of the FA and coumar in (internal standard) in serum of rabbit were calculated to make the calibration curves and the good linearity over the range (220-6710) \( \mu \text{g} \cdot \text{mL}^{-1} \) (TMP, \( r = 0.9990, n = 6 \)) and (20-800) \( \mu \text{g} \cdot \text{mL}^{-1} \) (FA, \( r = 0.9986, n = 6 \)) were obtained. Their equation of the curves were \( Y = 0.1889 + 0.0440X \) (TMP) and \( Y = 0.5826X + 0.1718 \) (FA). If the concentration of FA was above 800 \( \mu \text{g} \cdot \text{mL}^{-1} \), the sample was diluted. The detection limit of TMP and FA in sera were 68 mg·L\(^{-1} \) and 15 mg·L\(^{-1} \) respectively with a signal-to-noise ratio at 3.

The recoveries of TMP and FA contents from sera of rat and rabbit were determined. Their results are shown in Table 1.

The precision in sera with three levels (0.22 \( \mu \text{g} \cdot \text{mL}^{-1} \), 0.8388 \( \mu \text{g} \cdot \text{mL}^{-1} \) and 6.7100 \( \mu \text{g} \cdot \text{mL}^{-1} \)) of TMP and (0.030 \( \mu \text{g} \cdot \text{mL}^{-1} \), 0.450 \( \mu \text{g} \cdot \text{mL}^{-1} \) and 0.700 \( \mu \text{g} \cdot \text{mL}^{-1} \)) of FA was detected (Table 2).

| FA       | 0.4500             | 3.2            | 4.3            |
| FA       | 0.7000             | 2.1            | 3.8            |

The results of verifying S-PK
RMDS: Four days after ip injection of reserpine, RMDS showed decrease in activity, severe muscular hypotonia, palpebral ptosis and diarrhea, which were similar to those reported in our previously paper\(^{(15)}\) and accorded with the published diagnostic standard of spleen deficiency syndrome by Chinese Association of Integrated Traditional and Western Medicine\(^{(19)}\). In RMDS, the body weights of rats were reduced by 40\% (242 g ± 22 g vs 145 g ± 20 g), and in RMDS treated with SJZD, they had not shown any significant changes (results not shown).

The above analytical method of TMP was used to study TMP PK following oral TMPP. The pharmacokinetic profiles of oral TMPP in HR-1, RMDS and SJZD treated RMDS were the 2-compartment models according to the calculation of serum TMPP concentration-time data (Figure 2), which was in agreement with the results obtained from human and rats\(^{(20,21)}\). The serum concentrations of TMP in RMDS were higher than those in HR-1 (\(P<0.01\), Figure 2). The pharmacokinetic parameters of TMPP in RMDS (Table 3) with the exception of \(V/F\) and \(t\) peak were significantly different from those in HR-1 (\(P<0.01\); ka, \(T_{1/2a}\) ka, AUC, absorption of TMPP; \(\alpha\), \(\beta\), \(T_{1/2b}\), \(T_{12a}\), \(CLs\), \(K_{12}\), and \(K_{10}\) demonstrated that RMDS dec reased the rate of the distribution, transportation and clearance of TMPP (\(P<0.01\)). The state of the syndrome in RMDS affected obviously the absorption, distribution, metabolism and excretion of TMPP.

Table 3  Pharmacokinetic parameters of TMP in serum after oral administration of TMPP (10 mg/kg) to healthy rats and RMDS with or without SJZD treatment

| Parameter | Healthy rat | RMDS | SJZD |
|-----------|-------------|------|------|
| \(\alpha\) (h\(^{-1}\)) | 2.83 ± 0.70  | 0.38 ± 0.09\(*\) | 2.33 ± 0.65 |
| \(\beta\) (h\(^{-1}\)) | 0.22 ± 0.02  | 0.06 ± 0.30\(*\) | 0.24 ± 0.05 |
| \(K_{0\rightarrow\beta}\) | 5.41 ± 1.91  | 13.61 ± 2.56  | 5.28 ± 1.39 |
| \(K_{0\rightarrow\alpha}\) | 0.88 ± 0.20  | 0.24 ± 0.07\(*\) | 0.82 ± 0.11 |
| \(T_{1/2\alpha}\) | 1.45 ± 0.47  | 0.11 ± 0.02\(*\) | 1.39 ± 0.68 |

\(*\)\(P<0.01\) vs healthy rabbit.

RMBSS: the above method of detecting FA used to study PK in healthy rabbit and FA serum concentration in RMBSS compartment model was fitted and then pharmacokinetic parameters were calculated with a MCPKP program on a COMPAQ 80-386 computer. Compartmental analysis yielded a two-compartment open model. A rapid distribution phase followed by a slower elimination phase was observed. The mean pharmacokinetic parameters are given in Table 4 and serum concentration-time data in Figure 3.

The results of verifying R-PK
The results of detecting TMP concentrations in LW and LW&SM decoctions were 574.50 g·kg\(^{-1}\)·L\(^{-1}\) and 463.02 g·kg\(^{-1}\)·L\(^{-1}\), respectively.

The chromatograms of TMP and methaqualonum, the latter was added into serum, and then extracted, were the same as shown in Figure 1A, 1B. The serum TMP chromatogram after administration of LW or LW&SM decoctions was different from that of TMP and of IS added to blank serum (Figure 1A) as well as that of post-administration TMPP injection solution (Figure 1D). There were two more peaks of unknown significance in Figure 1C than that in Figure 1A and one more unknown peak than that in Figure 1D. The serum TCR-derived component parameters of 4 spectra of UV, IR, MS and NMR (data not shown) are similar to that of TMP standard substance and the reference value. Thus it gives an evidence to reveal that this TCR-derived component is undoubtedly TMP. The TMP PK were calculated by 3P87 program (Chinese Pharmacological Association). The fitted figures from two compartment open model and their parameters are indicated in Table 5.
Table 4 Pharmacokinetic parameters of FA in serum after intravenous administration of sodium ferulate (5 mg/kg) in healthy rabbit and rabbit with general blood stasis syndrome (x ± s, n = 6)

| Parameter          | RMBSS                   | Healthy rabbit                |

DISCUSSION

Hypothesis
The concept, terminology, essentials and significance, especially scientific evidences, of S- and R-PK hypothesis were firstly reported and theoretically elaborated in our previous papers[1-6]. These ideas were exclusively cited[22-26]. Besides the definition described in above method, we summarized the main elements as follows: (1) TCR-derived components in vivo are possibly to be detected; (2) their number are relatively restricted; (3) they could represent the therapeutic effect of the parent recipe; (4) their concentration and PK could be affected by the combination of TCM in TCR; (5) effects of new bioactive components related with those of their parent TCR; and (6) the syndrome state could affect their PK significantly. All the ideas of S- and R-PK exhibited the characteristics of combination of TCM theory and PK. The other two published papers only concerned the element 1[1-6]. So far, over 20 evidences in the available published literatures[2-8,12,13] supported the element 1.

Methodology
It is necessary to develop scientific analytical method, mainly chromatography, for verifying the hypothesis of S- and R-PK. In general, western drug component (single chemical substance) in blood is only identified by the consistency of retention time of peak in chromatograms as compared with its standard substance derived from the national and international authorized unit[27-29]. However, this method is not sufficient in analysing the serum TCR-derived component because the coherence of retention time may result from two possibilities, i.e., only a single component peak or an overlap of two or more component peaks according to the theory of chromatography[17].

We developed the above HPLC method, to determine the serum TMP PK after the administration of TMPP or TCR-LW. When TMPP

solution (Figure 1D) was administered, determination of TMP qualitatively and quantitatively by HPLC is enough corrodng to the method for determining ordinary western drug[27-29]. As orally administering LW or LW&SM decoctions, the structure of TMP was firstly identified by HPLC in combining with UV, IR, MS and NMR (Figure 1C) and then its concentration and pharmacokinetic value were determined by HPLC. Thus, it is ly avoid the analytical errors in serum TMP derived from LW or LW & SM in our present experiments[15-17]. Tables 1 and 2 indicated that these methods for the determinations of serum TMP and FA concentrations were simple, rapid, sens itive, accurate, specific and reduplicable, with high recoveries. All these inde xes were sufficient in studying S- and R-PK.

The verification of S-PK
S-PK hypothesis was advanced according to the theories of TCM and PK[1-6]. To verify this hypothesis, the animal models of spleen deficiency and blood stasis were chosen and their pharmacokinetic characteristics of TMP and FA were studied. One of these models, RMSDS, was induced by injecting reserpine, which h ad been used as an animal model for “spleen deficiency syndrome” (SDS) in TCM [30,31] because its physical signs were similar to those seen in the SDS.

The “spleen” digests food, transports, distributes and transforms nutrients and replenishes qi[32]. We inferred from the above “spleen theory” that the “spleen” should be also responsible for the absorption and disposal of drug. So, syndrome state of “spleen” is likely to affect the PK. The aim descri ed in the S-PK hypothesis is to demonstrate the pharmacokinetic differences between spleen deficiency and non-syndrome. Our experimental design from S-PK hypothesis is that the poor absorption of drug in SDS state would decrease its blood concen tration and bioavailability. On the contrary, Figure 2 and Table 3 show the resul ts of the increases in TMP serum concentration and AUC in RMSDS. Moreover, the parameters of the distribution and elimination of TMP in RMSDS (Table 3) were slowish. The SDS state could markedly affect the absorption, distribution, metabolism and elimination of TMPP in rat, and the observed results from Figure 2 and Table 3 show that SJZD could restore the above abnormal PK of TMPP in SDS model rats. All these TMP pharmacokinetic characteristics in RMSDS and the normalizing effect of SJZD on PK of TMP in RMSDS provided evidences for S-PK.

The mechanism of forming TMP pharmacokinetic characteristics in RMSDS is unknown. It was reported that the gastric and intestinal motility[33] and the absorptivity of D-xyl ose [34] were all decreased in reserpine-induced RMSDS and the patients with SDS. These observations are paradoxical to the increased serum TMP concentration in RMSDS. This confusion should be settled by further studies. Figure 3 shows that at corresponding time points the FA concentration in RMBSS increased markedly (P<0.05) as compared with normal rabbits. From Table 4 we also found that in RMBSS both the total volume of distribution (Vb) and total elimination rate (CLb) decreased significantly while FA elimination half-life time (t1/2b) and AUC increased significantly. This phenomenon may be due to the impairment of microcirculation induced by HMWD infusion. HMWD can lead to abnormal blood rheology (dense, sticky, aggregative, coagulative). So, it is impossible for FA to be metabolized quickly and distributed widely. In conclusion, through this experiment we found a significant difference in the pharmacokinetic parameters between healthy rabbits and RMBSS. This results are coincident with S-PK hypothesis.

The verification of R-PK hypothesis
So far, the orthodox academic society has thought that TCR-derived chemical components in vivo and their PK are not detectable and enable to study because they or their components are too complicated, trace in quantity or unable to represent curative effect of their parent TCR[35-38]. Therefore, the article related to above problem is rarely seen in recent years, and resulted in hard to explore the basic pharmacodynamic substance of TCR. The R-PK hypothesis emerged in literature since 1991 holds the idea that TCR-derived chemical components in vivo and their PK are possibly to be determined[1-6]. However, the qualitative and quantitative analysis of LW and LW&SM-derived TMP in vivo from Figure 1(C) and its PK from Figure 4 and Table 5 supported the R-PK hypothesis. Similarly, the determinations of over 20 TCR-derived chemical components in blood/urine and their PK[12,8,12,13,39] in published papers are consistent with the viewpoint of R-PK hypothesis. All these achievements help elucidate the pharmacology of TCM and TCR[39].

From the results provided in Figure 4 and Table 5 we found that the absorption (Ka), transport (K21) and distribution (Vc/F) of LW&SM-derived TMP in rat serum were decreased significantly compared with those of LW-derived TMP. In Figure 4 and Table 5 it also shows that the concentration and AUC of LW&SM-derived TMP in rat serum were lower than those of LW-derived TMP, which could explain why LW and SM are rarely used alone in a TCR. This viewpoint supported the hypothesis that the combination of drugs in TCR could affect pharmacokinetic parameters of TCR-derived component in vivo. It is extremely urgent to explore which component play an important role in the field of interaction of LW or LW&SM derived components in vivo.
