Kohlenbach’s proof mining program deals with the extraction of effective information from typically ineffective proofs. Proof mining has its roots in Kreisel’s pioneering work on the so-called unwinding of proofs. The proof mining of classical mathematics is rather restricted in scope due to the existence of sentences without computational content which are provable from the law of excluded middle and which involve only two quantifier alternations. By contrast, we show that the proof mining of classical Nonstandard Analysis has a very large scope. In particular, we will observe that this scope includes any theorem of pure Nonstandard Analysis, where ‘pure’ means that only nonstandard definitions (and not the epsilon-delta kind) are used. In this note, we survey results in analysis, computability theory, and Reverse Mathematics.

1 Introduction

The aim of this note is to survey the vast computational content of classical Nonstandard Analysis as established in \cite{34,35,36,37}. Results are mostly presented without proofs but references are provided.

First of all, numerous practitioners of Nonstandard Analysis have alluded to the constructive nature of its praxis; The following quotes serve as a representative illustration.

*It has often been held that nonstandard analysis is highly non-constructive, thus somewhat suspect, depending as it does upon the ultrapower construction to produce a model [...] On the other hand, nonstandard praxis is remarkably constructive; having the extended number set we can proceed with explicit calculations.* (Emphasis in original: \cite{1} p. 31)

*Those who use nonstandard arguments often say of their proofs that they are “constructive modulo an ultrafilter”; implicit in this statement is the suggestion that such arguments might give rise to genuine constructions.* (\cite{30} p. 494)

The reader may interpret the word constructive as the mainstream/classical notion ‘effective’, or as the foundational notion from Bishop’s *Constructive Analysis* \cite{7}. As will become clear, both cases will be treated below and separated carefully.

To uncover the computational content of Nonstandard Analysis alluded to in the above quotes, we shall introduce a template $\mathcal{CJ}$ in Section 3.2 which converts a theorem of pure Nonstandard Analysis into the associated ‘constructive’ theorem; Here, a theorem of ‘pure’ Nonstandard Analysis is one formulated solely with the nonstandard definitions (of continuity, convergence, etc) rather than the usual ‘epsilon-delta’ definitions. We present a wide range of applications of the template $\mathcal{CJ}$ in this note.

On a historical note, the late Grigori Mints has repeatedly pushed the author to investigate the computational content of classical Nonstandard Analysis. In particular, Mints conjectured the existence of
results analogous or similar to Kohlenbach’s *proof mining* program ([19]). The latter program has its roots in Kreisel’s pioneering work on the ‘unwinding’ of proofs, where the latter’s goal is similar to ours:

> To determine the constructive (recursive) content or the constructive equivalent of the non-constructive concepts and theorems used in mathematics, particularly arithmetic and analysis. (Emphasis in original on [22, p. 155])

Finally, Horst Osswald has qualified the observation from the above quotes as *Nonstandard Analysis is locally constructive*, to be understood as the fact that the mathematics performed in the nonstandard world is highly effective while the principles needed to ‘jump between’ the nonstandard world and usual mathematics, are highly non-constructive in general (See [45, §7], [28, §1-2], or [29, §17.5]). The results in this paper shall be seen to vindicate both the Mints and Osswald view.

## 2 About and around internal set theory

In this section, we introduce Nelson’s *internal set theory*, and its fragments P and H from [4]. We discuss the term extraction result in Corollary 2.2 which is central to our enterprise.

### 2.1 Internal set theory

In Nelson’s *syntactic* approach to Nonstandard Analysis ([25]), as opposed to Robinson’s semantic one ([31]), a new predicate ‘st(x)’, read as ‘x is standard’ is added to the language of ZFC, the usual foundation of mathematics. The notations (∀stx) and (∃sty) are short for (∀x)(st(x) → ...) and (∃y)(st(y) ∧ ...). A formula is *internal* if it does not involve ‘st’, and *external* otherwise. The three external axioms *Idealisation, Standard Part*, and *Transfer* govern the new predicate ‘st’; They are respectively defined as:

(I) (∀stfinx)(∃y)(∀z ∈ x)φ(z, y) → (∃y)(∀stx)φ(x, y), for internal φ with any parameters.

(S) (∀stx)(∃sty)(∀stz)((z ∈ x ∧ φ(z)) ↔ z ∈ y), for any φ.

(T) (∀stt)[(∀stx)φ(x, t) → (∀x)φ(x, t)], where φ(x, t) is internal, and only has free variables t, x.

The system IST is (the internal system) ZFC extended with the aforementioned external axioms; The former is a conservative extension of ZFC for the internal language, as proved in [25].

In [4], the authors study Gödel’s system T extended with special cases of the external axioms of IST. In particular, they introduce the systems H and P which are conservative extensions of the (internal) logical systems E-HA* and E-PA* respectively *Heyting and Peano arithmetic in all finite types and the axiom of extensionality*. We refer to [19, §3.3] and [4, §2] for the exact definitions of the (mainstream in mathematical logic) systems E-HA* and E-PA* and the associated extensions E-HA* and E-PA*. We refer to [35] and [37] for the exact definition of the systems P and H. Their importance lies in the *term extraction corollary* which we discuss in the next section.

Note that the contraposition of the idealisation axiom (I) allows one to ‘push outside’ a standard quantifier. The axiom (I) (formulated in the language of finite types) is included in P and H; We shall need this axiom in the proof of Theorem 3.6 and therefore list it as follows:

**Definition 2.1.** [Idealisation I] For any internal formula φ, we have

\[(∀stx^σ)(∃y^τ)(∀z^σ ∈ x)φ(z, y) → (∃y^τ)(∀stx^σ)φ(x, y),\] (2.1)

The superscript ‘fin’ in (I) means that x is finite, i.e. its number of elements are bounded by a natural number.
Note that $x^\sigma$ in the antecedent of (2.1) is a finite sequence of objects of type $\sigma$.

Finally, we note that IST is just ZFC with an extra unary predicate governed by the aforementioned axioms. In other words, all the usual definitions (of real function, large cardinal, Turing machine, etc) from ZFC can also be stated in IST by exactly the same formula of ZFC. The same holds for $P$ and $H$: In particular, the latter systems use Kohlenbach’s definition of real number and real function from [20] in the higher-type framework.

### 2.2 The term extraction corollary

In this section, we discuss the central tool of our investigation, namely the term extraction corollary of the system $P$, and sketch its vast scope. The following is essentially a corollary to [4, Theorem 7.7].

**Corollary 2.2 (Term extraction).** If $\Delta_{\text{int}}$ is a collection of internal formulas and $\psi$ is internal, and

$$P + \Delta_{\text{int}} \vdash (\forall^{| \mathcal{X}^* })(\exists^{| \mathcal{Y}^* })\psi(x, y, a),$$

then one can extract from the proof a sequence of closed terms $t$ in $\mathcal{P}^*$ such that

$$\text{E-PA}_0 + \Delta_{\text{int}} \vdash (\forall x)(\exists y \in t(x))\psi(x, y, a).$$

Note that $t$ does not provide a witnessing functional for $(\exists y)$ in (2.3): In particular $t(x)$ is only a finite sequence (of length $|t(x)|$) of witnesses for $(\exists y)$. For the remainder of this paper, the notion of ‘normal form’ shall always refer to a formula of the form $(\forall^{x^0} x)(\exists^{y^0} y)\varphi(x, y)$ with $\varphi$ internal, i.e. without ‘st’.

Curiously, the previous corollary is not proved in [4]: A proof making essential use of [4, Theorem 7.7] may be found in [35, 36]. The previous corollary is proved for the constructive system $H$ rather than the classical system $P$ in [4, Theorem 5.9], but our interest goes out to classical systems. Furthermore, Corollary 2.2 does not depend on the full strength of Peano arithmetic: The same result holds for any system which at least includes EFA, also called $I\Delta_0 + \text{EXP}$.

Clearly, Corollary 2.2 allows us to extract effective information (in the form of the term $t$) from proofs as in (2.2) in Nonstandard Analysis, to obtain effective results as in (2.3) not involving Nonstandard Analysis. We now discuss why Corollary 2.3 has such a vast scope, including all of ‘pure’ Nonstandard Analysis, as claimed in the introduction.

1. First of all, the nonstandard definitions of common notions (such as continuity, integrability, convergence, compactness, et cetera) in Nonstandard Analysis can be brought into the ‘normal form’ $(\forall^{x^0} x)(\exists^{y^0} y)\varphi(x, y)$. This can always be done in $P$ and usually in $H$. As an example, nonstandard continuity for $f : \mathbb{R} \to \mathbb{R}$ as follows (where ‘$x \approx y$’ is short for $(\forall^{x^0} n^0)((|x - y| < \mathbb{R} \frac{1}{N}))$):

$$(\forall^{x^0} x \in [0, 1])(\forall y \in [0, 1])|x \approx y \rightarrow f(x) \approx f(y)|.$$  

is equivalent (over $P$ or $H$) to the following normal form by Theorem 3.3:

$$(\forall^{x^0} x \in [0, 1])(\exists^{y^0} N^0)(\forall y \in [0, 1])(|x - y| < \mathbb{R} \frac{1}{N} \rightarrow |f(x) - f(y)| < \mathbb{R} \frac{1}{N}),$$

where the underlined formula is internal. Similar equivalences hold for nonstandard definitions of compactness, Riemann integration, differentiability, convergence, et cetera.
2. Secondly, the normal forms are closed under \textit{modus ponens}: Indeed, it is possible (easy in \( P \) and involved in \( H \)) to show that an implication between normal forms:

\[
(\forall^\text{st} x_0)(\exists^\text{st} y_0)\varphi_0(x_0, y_0) \rightarrow (\forall^\text{st} x_1)(\exists^\text{st} y_1)\varphi_1(x_1, y_1),
\]

can \textit{also} be brought into a normal form \((\forall^\text{st} x)(\exists^\text{st} y)\varphi(x, y)\). Hence, it seems theorems of ‘pure’ Nonstandard Analysis, i.e. formulated solely with nonstandard definitions like \((2.4)\), can be brought into the latter normal form. This can always be done in \( H \) and \( P \).

3. Third, normal forms are closed under quantification over the nonstandard numbers: In particular, for internal formulas \( \varphi(x, y, M) \), the following formula

\[
(\forall M^0)((\neg \text{st}(M) \rightarrow (\forall^\text{st} x)(\exists^\text{st} y)(\varphi(x, y, M))),
\]

is equivalent to a normal form in \( P \). The same holds for quantification over nonstandard higher-type objects. This item is significant because applications of Nonstandard Analysis often start with ‘divide the compact space at hand into pieces of infinitesimal surface/volume/measure \( \frac{1}{M^0} \).’

4. Fourth, the normal form \((\forall^\text{st} x)(\exists^\text{st} y)\varphi(x, y)\) has exactly the right structure to yield the effective version \((\forall x)(\exists t(x))\varphi(x, t(x))\). In particular, from the proof of the normal form \((\forall^\text{st} x)(\exists^\text{st} y)\varphi(x, y)\) (inside \( H \) or \( P \)), a term \( s \) can be ‘read off’ such that \((\forall x)(\exists y \in s(x))\varphi(x, y)\) has a proof inside a system involving \textit{no Nonstandard Analysis}. The term \( t \) is then defined in terms of \( s \). For theorems of analysis, \( \varphi(x, y) \) is often monotone in \( y \), and \( t \) is then just the maximum of all entries of \( s \). For instance, \((2.5)\) is ‘monotone in \( N \’ in the sense that any larger number than \( N \) will also do.

It is important to note that there is \textit{no general procedure} to convert the ‘weak witnessing’ term \( s \) into a ‘strong witnessing’ term \( t \) in the fourth step. However, when dealing with mathematical theorems (rather than purely logical statements), experience bears out that this conversion is almost always possible.

It goes without saying that most technical details have been omitted from the above sketch, this in order to promote intuitive understanding. Nonetheless, the previous four steps form the skeleton of the template \( \mathcal{CI} \) introduced in Section \( 3.2 \). In light of the previous observations, the class of normal forms, and hence the scope of \( \mathcal{CI} \), seems to be \textit{very large}, which is what we intend to establish in the remainder.

Finally, the results in this note should be contrasted with the ‘mainstream’ view of Nonstandard Analysis: One usually thinks of the universe of standard objects as ‘the usual world of mathematics’, which can be studied ‘from the outside’ using nonstandard objects such as infinitesimals. In this richer framework, proofs can be much shorter than those from standard (=non-Nonstandard) analysis; Furthermore, there are \textit{conservation results} guaranteeing that theorems of usual mathematics \textit{proved using Nonstandard Analysis} can also be proved \textit{without using Nonstandard Analysis}. Thus, the starting and end point (according to the mainstream view) is always the universe of standard objects, i.e. usual mathematics. By contrast, our starting point is \textit{pure} Nonstandard Analysis and our end point is effective mathematics.

3 \textbf{An elementary example} \quad

In this section, we present an elementary example which we believe to be enlightening. Based on this example, we formulate a general template \( \mathcal{CI} \) to obtain effective theorems from nonstandard ones.
3.1 From continuity to Riemann integration

In this section, we study the statement CRI: *A uniformly continuous function on the unit interval is Riemann integrable.* We first obtain the effective version of CRI from the nonstandard version inside $\mathbb{P}$. We then obtain the same result in the constructive system $\mathbb{H}$. Finally, we re-obtain the nonstandard version from a special effective version, called the Hebrandisation.

First of all, the ‘usual’ nonstandard definitions of continuity and integration are as follows. Recall that ‘$x \approx y$’ is an abbreviation for ‘$(\forall n)(|x - y| <_{\mathbb{R}} \frac{1}{n})$’.

**Definition 3.1.** [Continuity] A function $f : \mathbb{R} \to \mathbb{R}$ is nonstandard continuous on $[0, 1]$ if

$$\forall x, y \in [0, 1] \exists M \ |x - y| <_{\mathbb{R}} \frac{1}{M} \implies |f(x) - f(y)| <_{\mathbb{R}} \frac{1}{M}.$$  

A function $f : \mathbb{R} \to \mathbb{R}$ is nonstandard uniformly continuous on $[0, 1]$ if

$$\forall x, y \in [0, 1] \ |x - y| <_{\mathbb{R}} \frac{1}{M} \implies |f(x) - f(y)| <_{\mathbb{R}} \frac{1}{M}.$$  

**Definition 3.2.** [Integration]

1. A partition of $[0, 1]$ is any sequence $\pi = (0, t_0, x_1, t_1, \ldots, x_{M-1}, t_{M-1}, 1)$. We write ‘$\pi \in P([0, 1])$’ to denote that $\pi$ is such a partition.
2. For $\pi \in P([0, 1])$, $\|\pi\|$ is the mesh, i.e. the largest distance between two partition points $x_i$ and $x_{i+1}$.
3. For $\pi \in P([0, 1])$ and $f : \mathbb{R} \to \mathbb{R}$, $S_\pi(f) := \sum_{i=0}^{M-1} f(t_i)(x_i - x_{i+1})$ is the Riemann sum of $f$ and $\pi$.
4. A function $f : \mathbb{R} \to \mathbb{R}$ is nonstandard Riemann integrable on $[0, 1]$ if

$$\forall \pi, \pi' \in P([0, 1]) \ |\|\pi\|, \|\pi'\| \approx 0 \implies S_\pi(f) \approx S_{\pi'}(f).$$  

Secondly, it was claimed in the previous section that nonstandard continuity has a nice normal form.

**Theorem 3.3 (P).** Nonstandard uniform continuity (3.2) is equivalent to

$$\forall k \exists N \forall x, y \in [0, 1] \ |x - y| <_{\mathbb{R}} \frac{1}{N} \implies |f(x) - f(y)| <_{\mathbb{R}} \frac{1}{k},$$  

(3.4)

**Proof.** We only need to prove the forward implication. Resolving ‘$\approx$’ in (3.2), we obtain

$$\forall x, y \in [0, 1] \exists N \ |x - y| <_{\mathbb{R}} \frac{1}{N} \implies |f(x) - f(y)| <_{\mathbb{R}} \frac{1}{k},$$

and pushing outside all standard quantifiers, we obtain

$$\forall x, y \in [0, 1] \exists M \ |x - y| <_{\mathbb{R}} \frac{1}{M} \implies |f(x) - f(y)| <_{\mathbb{R}} \frac{1}{k},$$

where the underlined formula is internal. Applying the contraposition of idealisation $\mathsf{l}$ as in (2.1):

$$\forall x, y \in [0, 1] \exists N \ |x - y| <_{\mathbb{R}} \frac{1}{N} \implies |f(x) - f(y)| <_{\mathbb{R}} \frac{1}{k}.$$  

Now let $M$ be the maximum of all numbers in $w = (n_0^0, \ldots, n_k^0)$, and note that

$$\forall x, y \in [0, 1] \ |x - y| <_{\mathbb{R}} \frac{1}{M} \implies |f(x) - f(y)| <_{\mathbb{R}} \frac{1}{k},$$

by the monotonicity of the internal formula. This is exactly (3.4), and we are done. \qed
Thirdly, we now introduce the nonstandard and effective versions of CRI as follows.

**Theorem 3.4** (CRI$_{ns}$). Every nonstandard uniformly continuous function on the unit interval is nonstandard Riemann integrable there.

**Theorem 3.5** (CRI$_{ef}(t)$). For any $f : \mathbb{R} \to \mathbb{R}$ with modulus of uniform continuity $g$, the functional $t(g)$ is a modulus of Riemann integration, i.e. we have

$$(\forall x, y \in [0, 1], k)(|x - y| < \frac{1}{g(k)} \to |f(x) - f(y)| \leq \frac{1}{k})$$

$$\to (\forall n)(\forall \pi, \pi' \in P([0, 1]))(|\pi|, |\pi'| < \frac{1}{t(g(n))} \to |s_\pi(f) - s_{\pi'}(f)| \leq \frac{1}{n}).$$

Kohlenbach has shown that continuous real-valued functions as represented in RM (See [39, II.6.6] and [19, Prop. 4.4]) have a modulus of (pointwise) continuity as in the antecedent of (3.5).

**Theorem 3.6.** From a proof of CRI$_{ns}$ in $P$, a term $t$ can be extracted such that E-PA$^0_1$ proves CRI$_{ef}(t)$.

**Proof.** The theorem CRI$_{ns}$ can be proved in far weaker systems than $P$ by [33, Theorem 19]. A variation of the latter proof may be found in [35, §3.1.1]. We now sketch how to obtain a normal form for CRI$_{ns}$. Applying Corollary [2.2] to this normal form will then yield CRI$_{ef}(t)$.

First of all, a normal form for uniform nonstandard continuity (3.2) is (3.4), while the (equivalent) normal form for nonstandard Riemann integration similarly is:

$$(\forall^STM^0)(\exists^ST)(\forall \pi, \pi' \in P([0, 1]))(|\pi|, |\pi'| < \frac{1}{M} \to |s_\pi(f) - s_{\pi'}(f)| < 1).$$

Secondly, in light of the previous equivalences, CRI$_{ns}$ is the implication (3.4) $\to$ (3.6) for all $f : \mathbb{R} \to \mathbb{R}$. By strengthening the antecedent of the latter implication, we obtain for all $f : \mathbb{R} \to \mathbb{R}$ and all standard $g$:

$$(\forall^ST)(\forall x, y \in [0, 1])(|x - y| < \frac{1}{g(k)} \to |f(x) - f(y)| \leq \frac{1}{k})$$

$$\to (\forall^SN)(\exists^ST)(\forall \pi, \pi' \in P([0, 1]))(|\pi|, |\pi'| < \frac{1}{M} \to |s_\pi(f) - s_{\pi'}(f)| \leq \frac{1}{n}).$$

Now drop the ‘st’ in the ‘(\forall^ST)’ quantifier in (3.7), and bring outside all standard quantifiers to obtain:

$$(\forall^SN, g)(\forall f : \mathbb{R} \to \mathbb{R})(\exists^ST)(\forall \pi, \pi' \in P([0, 1]))(|\pi|, |\pi'| < \frac{1}{M} \to |s_\pi(f) - s_{\pi'}(f)| \leq \frac{1}{n}).$$

Applying idealisation (I), we obtain that:

$$(\forall^SN, g)(\forall f : \mathbb{R} \to \mathbb{R})(\exists^ST)(\forall \pi, \pi' \in P([0, 1]))(|\pi|, |\pi'| < \frac{1}{M} \to |s_\pi(f) - s_{\pi'}(f)| \leq \frac{1}{n}).$$

Now let $N$ be the maximum of all numbers in $w$ from (3.9), and note that

$$(\forall^SN, g)(\forall f : \mathbb{R} \to \mathbb{R})(\exists^ST)(\forall \pi, \pi' \in P([0, 1]))(|\pi|, |\pi'| < \frac{1}{M} \to |s_\pi(f) - s_{\pi'}(f)| \leq \frac{1}{n}).$$
due to the monotone behaviour of the consequent. Now apply the term extraction corollary to \(P \vdash (3.10)\) to obtain a term \(s\) such that E-PA\(^{\omega*}\) proves

\[
(\forall n, g)(\exists N \in s(g, n)) \left( (\forall f : \mathbb{R} \to \mathbb{R}) \left( (\forall k, x, y \in [0, 1]) (|x - y| < \frac{1}{g(k)} \to |f(x) - f(y)| \leq \frac{1}{k}) \right) \right)
\]

\[\to (\forall \pi, \pi' \in \mathcal{P}([0, 1])) (||\pi||, ||\pi'|| < \frac{1}{\pi(g, k)} \to |S_{\pi}(f) - S_{\pi'}(f)| \leq \frac{1}{\pi'})\]

(3.11)

Define \(t(g, n)\) as the maximum number of \(s(g, n)\), and note that (3.11) implies CR\(_{\infty}(t)\), again due to the monotone behaviour of the consequent.

**Corollary 3.7.** Theorem 3.6 also goes through constructively, i.e. we can prove CR\(_{\infty}\) in \(H\) and a term \(t\) can be extracted such that E-HA\(^{\omega*}\) proves CR\(_{\infty}(t)\).

**Proof.** The proof of CR\(_{\infty}\) in [33] is clearly constructive in the sense of \(H\). A careful inspection of the proof of the theorem shows that (3.10) can also be derived in \(H\) from CR\(_{\infty}\). Applying the term extraction result for \(H\) ([1, Theorem 5.6]) then yields the corollary. A full proof is in [35] §3.1.

Finally, define the Herbrandisation of CR\(_{\infty}\) as follows:

\[
(\forall f, g, k') \left[ (\forall k \leq s(g, k')) (\forall x, y \in [0, 1]) (|x - y| < \frac{1}{g(k)} \to |f(x) - f(y)| \leq \frac{1}{k}) \right]
\]

\[
\to (\forall \pi, \pi' \in \mathcal{P}([0, 1])) (||\pi||, ||\pi'|| < \frac{1}{\pi(g, k')} \to |S_{\pi}(f) - S_{\pi'}(f)| \leq \frac{1}{\pi'})
\]

(CR\(_{\infty}\)\(_{\text{her}}\)(s, t))

The Herbrandisation CR\(_{\infty}\)\(_{\text{her}}\)(s, t) follows from CR\(_{\infty}\) in the same way as in the theorem. In particular, we obtain the former if we do not drop the `st` in `(\forall^{\omega\omega}k)` to obtain (3.8). We have the following corollary.

**Corollary 3.8.** Let \(t\) be a term in the internal language. A proof inside E-PA\(^{\omega*}\) of the Herbrandisation CR\(_{\infty}\)\(_{\text{her}}\)(s, t), can be extracted into a proof inside \(P\) of CR\(_{\infty}\).

**Proof.** The basic axioms of \(P\) state that any term of the internal language is standard. The rest of the corollary is now straightforward. A full proof is in [35] §3.1.

### 3.2 The template \(\mathcal{CJ}\)

In this section, we formulate the template \(\mathcal{CJ}\) based on the above case study. We emphasize that some aspects of \(\mathcal{CJ}\) are inherently vague. Recall from the previous section that a ‘normal form’ is a formula of the form \((\forall^{\omega\omega}x)(\exists^{\omega\omega}y)\varphi(x, y)\) with \(\varphi\) internal.

**Template 3.9 (\(\mathcal{CJ}\)).** The starting point for \(\mathcal{CJ}\) is a theorem \(T\) formulated in the language of E-PA\(^{\omega*}\).

(i) Replace in \(T\) all definitions (convergence, continuity, et cetera) by their well-known counterparts from Nonstandard Analysis. For the resulting theorem \(T^*\), look up the proof (e.g. in [17,41,45]) and formulate it inside \(P\) or \(H\) if possible. If \(T^*\) cannot be proved in \(P\), consider \(A \to T^*\), where \(A\) is a collection of external axioms from IST to guarantee the provability in \(P\).

(ii) Bring all nonstandard definitions in \(T^*\) into the normal form \((\forall^{\omega\omega}x)(\exists^{\omega\omega}y)\varphi(x, y)\). This operation usually requires \(I\) for \(P\), and usually requires extra axioms for \(H\). If necessary, drop `st` in leading existential quantifiers of positively occurring formulas (like to obtain (3.8)).

(iii) Starting with the most deeply nested implication, bring

\[
(\forall^{\omega\omega}x_0)(\exists^{\omega\omega}y_0)\varphi_0(x_0, y_0) \to (\forall^{\omega\omega}x_1)(\exists^{\omega\omega}y_1)\varphi_1(x_1, y_1),
\]

(3.12)

into a normal form \((\forall^{\omega\omega}x)(\exists^{\omega\omega}y)\varphi(x, y)\).
(iv) Apply Corollary 2.2 (if applicable [4, Theorem 5.6] for H) to the proof of the normal form of \( T^* \).
(v) Output the term(s) \( t \) and the proof(s) of the effective version. Modify these terms for monotone formulas if necessary.

The theorems in the above case study all had proofs inside \( H \) or \( P \), i.e. the final sentence in step (i) does not apply. In Section 4.2, we shall study theorems for which we do have to add external axioms of IST to the conditions of the theorem.

Finally, there is a tradition of Nonstandard Analysis in RM and related topics (See e.g. [16, 40, 42, 44, 47–49]), which provides a source of proofs in (pure) Nonstandard Analysis for \( \mathcal{N} \). To automate the process of applying \( \mathcal{N} \), we have initiated the implementation of the term extraction algorithm from Corollary 2.2 in Agda, which is work in progress at this time ([46]).

4 Reverse Mathematics

In this section, we first introduce the program Reverse Mathematics, and then list results regarding the main systems consider therein.

4.1 Introducing Reverse Mathematics

Reverse Mathematics (RM) is a program in the foundations of mathematics initiated around 1975 by Friedman ([11, 12]) and developed extensively by Simpson ([38, 39]) and others. The aim of RM is to find the axioms necessary to prove a statement of ordinary mathematics, i.e. dealing with countable or separable spaces. The classical base theory \( \text{RCA}_0 \) of ‘computable mathematics’ is always assumed. Thus, the aim of RM is as follows:

\[
\text{The aim of RM is to find the minimal axioms } A \text{ such that } \text{RCA}_0 \vdash [A \rightarrow T] \text{ for statements } T \text{ of ordinary mathematics.}
\]

Surprisingly, once the minimal axioms \( A \) have been found, we almost always also have \( \text{RCA}_0 \vdash [A \leftrightarrow T] \), i.e. not only can we derive the theorem \( T \) from the axioms \( A \) (the ‘usual’ way of doing mathematics), we can also derive the axiom \( A \) from the theorem \( T \) (the ‘reverse’ way of doing mathematics). In light of the latter, the field was baptised ‘Reverse Mathematics’.

Perhaps even more surprisingly, in the majority of cases for a statement \( T \) of ordinary mathematics, either \( T \) is provable in \( \text{RCA}_0 \), or the latter proves \( T \leftrightarrow A_i \), where \( A_i \) is one of the logical systems \( \text{WKL}_0, \text{ACA}_0, \text{ATR}_0 \) or \( \Pi^1_1\text{-CA}_0 \). The latter together with \( \text{RCA}_0 \) form the ‘Big Five’ and the aforementioned observation that most mathematical theorems fall into one of the Big Five categories, is called the Big Five phenomenon ([24 p. 432]). Furthermore, each of the Big Five has a natural formulation in terms of (Turing) computability (See e.g. [39 I.3.4, I.5.4, I.7.5]). As noted by Simpson in [39 I.12], each of the Big Five also corresponds (sometimes loosely) to a foundational program in mathematics.

The logical framework for Reverse Mathematics is second-order arithmetic, in which only natural numbers and sets thereof are available. As a result, functions from reals to reals are not available, and have to be represented by so-called codes (See [39 II.6.1]). In the latter case, the coding of continuous

---

2In Constructive Reverse Mathematics ([18]), the base theory is based on intuitionistic logic.
3The system \( \text{RCA}_0 \) consists of induction \( \Sigma^0_1 \), and the recursive comprehension axiom \( \Delta^0_1\text{-CA} \).
4Exceptions are classified in the so-called Reverse Mathematics Zoo ([8]).
functions amounts to introducing a modulus of (pointwise) continuity (See \cite{21}, \S 4). The nonstandard theorems proved in the system \( \mathbb{P} \) will not involve coding (for continuous functions or otherwise); However, as will become clear below, a modulus of continuity naturally ‘falls out of’ the nonstandard definition of continuity as in (2.4). Thus, the nonstandard framework seems to ‘do the coding for us’.

In light of the previous, one of the main results of RM is that mathematical theorems fall into only five logical categories. By contrast, there are lots and lots of (purely logical or non-mathematical) statements which fall outside of these five categories. Similarly, most mathematical theorems from Nonstandard Analysis have the normal from required for applying term extraction via Corollary \cite{22}, while there are plenty of non-mathematical or purely logical statements which do not. In conclusion, the results in this paper are inspired by the Reverse Mathematics way of thinking that mathematical theorems (known in the literature) will behave ‘much nicer’ than arbitrary formulas (even of restricted complexity). In particular, since there is no meta-theorem for the (Big Five and its zoo) classification of RM, one cannot hope to obtain a meta-theorem for the template \( \mathcal{C} \mathcal{J} \) from Section \ref{sec:nonstandard}.

4.2 The Big Five

In this section, we list the results of applying \( \mathcal{C} \mathcal{J} \) to equivalences involving the strongest three Big Five systems. We do not go into the details regarding \( \text{WKL}_0 \) because of a lack of space. Proofs may be found in \cite{35}, \S 4.

4.2.1 Theorems equivalent to \( \text{ACA}_0 \)

In this section, we study the monotone convergence theorem MCT, i.e. the statement that every bounded increasing sequence of reals is convergent, which is equivalent to arithmetical comprehension \( \text{ACA}_0 \) by \cite{39}, III.2.2). We prove an equivalence between a nonstandard version of MCT and a fragment of Transfer. From this nonstandard equivalence, we obtain an effective RM equivalence involving MCT and arithmetical comprehension by applying \( \mathcal{C} \mathcal{J} \).

Firstly, the nonstandard version of MCT (involving nonstandard convergence) is:

\[
(\forall^{st}_{c(\cdot)} c^{0\rightarrow 1}_{(\cdot)})(\forall n^0)(c_n \leq c_{n+1} \leq 1) \rightarrow (\forall N, M \in \Omega)[c_M \approx c_N],
\]  \hspace{1cm} (MCT_{ns})

where ‘(\forall K \in \Omega)(\ldots)’ is short for (\forall K^0)(\neg \text{st}(K) \rightarrow \ldots). The effective version \( \text{MCT}_{ef}(t) \) is:

\[
(\forall^{st}_{c(\cdot)} c^{0\rightarrow 1}_{(\cdot)}, k^0)(\forall n^0)(c_n \leq c_{n+1} \leq 1) \rightarrow (\forall N, M \geq t(c_{(\cdot)})(k))[|c_m - c_N| \leq 1/k].
\]  \hspace{1cm} (4.1)

We require two equivalent (\cite{20}, Prop. 3.9) versions of arithmetical comprehension:

\[
(\exists \mu^2)[(\forall f^1)((\exists n)f(n) = 0 \rightarrow f(\mu(f)) = 0)],
\]  \hspace{1cm} (\mu^2)

\[
(\exists \varphi^2)[(\forall f^1)((\exists n)f(n) = 0 \leftrightarrow \varphi(f) = 0)],
\]  \hspace{1cm} (\varphi^2)

and also the restriction of Nelson’s axiom \( \text{Transfer} \) as follows:

\[
(\forall^{st} f^1)[(\forall^{st} n^0)f(n) \neq 0 \rightarrow (\forall m)f(m) \neq 0].
\]  \hspace{1cm} (\Pi^0_1-\text{TRANS})

Denote by \( \text{MU}(\mu) \) the formula in square brackets in (\mu^2). We have the following theorem which establishes the explicit equivalence between (\mu^2) and uniform MCT.
Theorem 4.1. From $P \vdash \text{MCT}_{ns} \leftrightarrow \Pi^0_1\text{-TRANS}$, terms $s, u$ can be extracted such that $E\text{-PA}^{0\omega}$ proves:

$$\left(\forall \mu^2\right) \left[\text{MU}(\mu) \rightarrow \text{MCT}_{st}(s(\mu))\right] \land \left(\forall t^{1\rightarrow 1}\right) \left[\text{MCT}_{st}(t) \rightarrow \text{MU}(u(t))\right].$$

(4.2)

Proof. Apply $\mathcal{C} \mathcal{J}$ to $\text{MCT}_{ns} \leftrightarrow \Pi^0_1\text{-TRANS}$; The proof of the latter in [36, §4.1] is rather elementary. □

4.2 Theorems equivalent to $\text{ATR}_0$ and $\Pi^1_1\text{-CA}_0$

In this section, we study equivalences relating to $\text{ATR}_0$ and $\Pi^1_1\text{-CA}_0$, the strongest Big Five systems from RM. The associated results show that the template $\mathcal{C} \mathcal{J}$ also works for the fourth and fifth Big Five system.

We shall work with the Suslin functional $(S^2)$, the functional version of $\Pi^1_1\text{-CA}_0$.

$$(\exists S^2)(\forall f^1)[S(f) = 0 \leftrightarrow (\exists g^1)(\forall x^0)(f(\bar{g} x) \neq 0)].$$

(S^2)

Feferman has introduced the following version of the Suslin functional (See e.g. [3]).

$$(\exists \mu^1)^{1\rightarrow 1} \left[ (\forall f^1)(\exists g^1)(\forall x^0)(f(\bar{g} x) \neq 0) \rightarrow (\forall x^0)(f(\bar{\mu} f(x) \neq 0)) \right],$$

(\mu_1)

where the formula in square brackets is denoted $\text{MUO}(\mu_1)$. We shall require another instance of Transfer:

$$(\forall f^1)[(\exists g^1)(\forall x^0)(f(\bar{g} x) \neq 0) \rightarrow (\exists^{\mu_1} g^1)(\forall x^0)(f(\bar{g} x) \neq 0)].$$

($\Pi^1_1\text{-TRANS}$)

We shall obtain an effective version of the equivalence proved in [32, Theorem 4.4]. The relevant (non-uniform) principle pertaining to the latter is $\text{PST}$, i.e. the statement that every tree with uncountably many paths has a non-empty perfect subtree. The latter has the following nonstandard and effective versions.

Theorem 4.2 ($\text{PST}_{ns}$). For all standard trees $T^1$, there is standard $P^1$ such that

$$(\forall f^0)^{1\rightarrow 1}(\exists f \in T)(\forall n)(f_n \neq 1 f) \rightarrow P \text{ is a non-empty perfect subtree of } T.$$

Theorem 4.3 ($\text{PST}_{st}(t)$). For all trees $T^1$, we have

$$(\forall f^0)^{1\rightarrow 1}(\exists f \in T)(\forall n)(f_n \neq 1 f) \rightarrow t(T) \text{ is a non-empty perfect subtree of } T.$$

As a technicality, we require that $P$ as in the previous two principles consists of a pair $(P', p')$ such that $P'$ is a perfect subtree of $T$ such that $p' \in E'$. We have the following theorem.

Theorem 4.4. From $P \vdash \text{PST}_{ns} \leftrightarrow \Pi^1_1\text{-TRANS}$, terms $s, u$ can be extracted such that $E\text{-PA}^{0\omega}$ proves:

$$(\forall \mu)[\text{MUO}(\mu) \rightarrow \text{PST}_{st}(s(\mu)))] \land (\forall t^{1\rightarrow 1}) \left[\text{PST}_{st}(t) \rightarrow \text{MUO}(u(t))\right].$$

(4.3)

In light of the intimate connection between theorems concerning perfect kernels of trees and the Cantor-Bendixson theorem for Baire space (See [39, IV.1]), a version of Theorem 4.4 for the former can be obtained in a straightforward way. Another more mathematical statement which can be treated along the same lines is every countable Abelian group is a direct sum of a divisible and a reduced group. The latter is called $\text{DIV}$ and equivalent to $\Pi^1_1\text{-CA}_0$ by [39, VI.4.1]. By the proof of the latter, the reverse implication is straightforward; We shall study $\text{DIV} \rightarrow \Pi^1_1\text{-CA}_0$.

To this end, let $\text{DIV}(G, D, E)$ be the statement that the countable Abelian group $G$ satisfies $G = D \oplus E$, where $D$ is a divisible group and $E$ a reduced group. The nonstandard version of $\text{DIV}$ is as follows:

$$(\forall^a G)(\exists^a D, d, E) \left[ \text{DIV}(G, D, E) \land (D \neq \{0_G\} \rightarrow d \in D) \right],$$

(DIV$_{ns}$)
where we used the same technicality as for PSTns. The effective version is:

\[(\forall G)[\text{DIV}(G,t(G)(1),t(G)(2)) \land (t(G)(1) \neq 0_G) \rightarrow t(G)(3) \in t(G)(1))]. \tag{\text{DIV}_e(t)}\]

We have the following (immediate) corollary.

**Corollary 4.5.** From $P \vdash \text{DIV}_ns \rightarrow \Pi^1_1\text{-TRANS}$, a term $u$ can be extracted such that $\text{E-PA}^{\alpha*}$ proves:

\[(\forall t^{1 \rightarrow 1})[\text{DIV}_e(t) \rightarrow \text{MUO}(u(t))]. \tag{4.4}\]

### 4.3 The Reverse Mathematics zoo

The Reverse Mathematics zoo is a collection of theorems which do not fit the ‘Big Five’ categories (8). In [36,37], a variant of $\mathcal{C} \mathcal{J}$ is used to classify uniform versions of the RM zoo as equivalent to arithmetical comprehension ($3^2$). We list the relevant results for one theorem from the RM zoo, namely DNR as defined below. All known theorems from the RM zoo have been classified in the same way.

Thus, consider the principle UDNR as follows: $(\exists \Psi^{1 \rightarrow 1})[(\forall e^0)(\Psi(A)(e) \neq \Phi^A_0(e))].$ Clearly, UDNR is the uniform version of the zoo principle$^5$ DNR defined as: $(\forall A^1)(\exists f^1)(\forall e^0)[f(e) \neq \Phi^A_0(e)].$

The principle DNR was first formulated in [15] and is even strictly implied by WWKL (See [2]) where the latter principle sports some Reverse Mathematics equivalences ([24,50,51]) but is not a Big Five system. Nonetheless, it is the case that UDNR $\Leftrightarrow (3^2).$ In other words, the ‘exceptional’ status of DNR disappears completely if we consider its uniform version UDNR.

To prove that UDNR is equivalent to arithmetical comprehension, we consider UDNR$^+$:

\[(\exists^u \Psi^{1 \rightarrow 1})[(\forall^u A^1)(\forall e^0)(\Psi(A)(e) \neq \Phi^A_0(e)) \land (\forall^u C^1,D^1)(C \approx_1 D \rightarrow \Psi(C) \approx_1 \Psi(D))].\]

where $A \approx_1 B$ if $(\forall^u n)(A(n) = B(n)).$ The second conjunct expresses that $\Psi$ is standard extensional.

**Theorem 4.6.** In $P$, we have UDNR$^+ \leftrightarrow \Pi^0_1\text{-TRANS}.$

Denote by UDNR($\Psi$) the formula in square brackets in UDNR.

**Theorem 4.7.** From $P \vdash \text{UDNR}^+ \leftrightarrow \Pi^0_1\text{-TRANS}$ terms $s,u$ can be extracted such that $\text{E-PA}^{\alpha*}$ proves:

\[(\forall \mu^2)[\text{MU}(\mu) \rightarrow \text{UDNR}(s(\mu))] \land (\forall \Psi^{1 \rightarrow 1})[\text{UDNR}(\Psi) \rightarrow \text{MU}(u(\Psi, \Xi))], \tag{4.5}\]

where $\Xi$ satisfies $(\forall A^1,B^1,k^0)(\Xi(A,b,k) = \Xi(A,B,k) \rightarrow \Psi(A)(k) = \Psi(B)(k)).$

In the previous theorem, we say that $\Xi$ is an extensionality functional for $\Psi$, as the former witnesses the axiom of extensionality for the latter. Proofs of the previous theorems may be found in [36], while a general template to similarly treat theorems from the Reverse Mathematics zoo may be found in [36,37]. As it turns out, these proofs also go through relative to Heyting arithmetic ([37]).

### 5 The Gandy-Hyland functional

In this section, we apply $\mathcal{C} \mathcal{J}$ to computability theory by studying the Gandy-Hyland functional. Proofs and additional results may be found in [34].

---

$^5$We sometimes refer to inhabitants of the RM zoo as ‘theorems’ and sometimes as ‘principles’.
5.1 Introducing the Gandy-Hyland functional $\Gamma$

The Gandy-Hyland functional was introduced in [13] as an example of a higher-type functional not computable, in the sense of Kleene’s S1-S9 (See [26] 1.10 or [23] 5.1.1), in the fan functional over the total continuous functionals (See [26] 4.61 or [23] 8.3.3). The Gandy-Hyland functional $\Gamma$ is:

$$(\exists \forall^3)(\forall Y^2 \in C, s^0)[\Gamma(Y^2, s^0) = Y(s \ast 0 \ast (\lambda n^0)\Gamma(Y, s \ast (n + 1)))], \quad (\text{GH})$$

where ‘$Y^2 \in C$’ is the usual definition of pointwise continuity on Baire space as in (5.1). We adopt the usual notational conventions as in e.g. [6].

$$(\forall f^1)(\exists N^0)(\forall g^1)(\exists N = 0 \overline{\exists} N \rightarrow Y(f) = 0) Y(g)). \quad (5.1)$$

The functional $\Gamma$ from (GH) apparently exhibits non-well-founded self-reference: Indeed, in order to compute $\Gamma$ at $s^0$, one needs the values of $\Gamma$ at all child nodes of $s^0$, as is clear from the right-hand side of (GH). In turn, to compute the value of $\Gamma$ at the child nodes of $s$, one needs the value of $\Gamma$ at all grand-child nodes of $s$, and so on. Hence, repeatedly applying the definition of $\Gamma$ seems to result in a non-terminating recursion. By contrast, primitive recursion is well-founded as it reduces the case for $n + 1$ to the case for $n$, and the case for $n = 0$ is given.

As it turns out, the Gandy-Hyland functional as in (GH) can be approximated in Nonstandard Analysis by the following primitive recursive\(^6\) functional:

$$G(Y, s, M) = \begin{cases} Y(s \ast 00 \ldots) & |s| \geq M \\ Y(s \ast 0 \ast (\lambda n^0)G(Y, s \ast (n + 1), M)) & \text{otherwise} \end{cases} \quad (5.2)$$

Indeed, $G$ as in (5.2) equals the $\Gamma$-functional from (GH) for standard input and any nonstandard number $M^0$ (See Section 5.2). Note that one needs only apply the definition of $G$ at most $M$ times to terminate in the first case of (5.2). In other words, the extra case ‘$|s| \geq M$’ provides a nonstandard stopping condition which ‘unwinds’ the non-terminating recursion in $\Gamma$ to the terminating one in $G$. Or: one can trade in self-reference for nonstandard numbers. Thus, we shall refer to $G$ as the canonical approximation of $\Gamma$.

To be absolutely clear, all systems mentioned in this paper deal with total functionals only. In particular, in the system $P + (GH)$, there is a functional $\Gamma^0$ which behaves as described in (GH) for $Y^2 \in C$, while $\Gamma(Z, s)$ is a natural number for discontinuous $Z^2$ and $s^0$, but we have no additional information. The same convention applies to the modulus-of-continuity functional defined in the next section.

5.2 Term extraction and $\Gamma$

In this section, we show that $\Gamma$ equals its canonical approximation $G$ assuming certain fragments of Transfer and Standard Part as in Theorem 5.1. Applying $\exists \forall$ to this result, one obtains a term $t$ expressing the Gandy-Hyland functional in terms of the modulus-of-continuity functional and a special case of the fan functional, as in Corollary 5.2. To this end, we need the following nonstandard axioms:

$$(\forall a Y^2 \in C, s^0)[\Gamma(Y^2, s^0) = Y(s \ast 0 \ast (\lambda n^0)\Gamma(Y, s \ast (n + 1)))]. \quad (\text{GH}_{st}(\Gamma))$$

$$(\forall a f^1)[(\exists m^0)(\forall n^0)f(m, n) = 0 \rightarrow (\exists k^0)(\forall l^0)f(k, l) = 0]. \quad (\Sigma_2^0\text{-TRANS})$$

\(^6\)The functional $G$ is primitive recursive in the sense of Gödel’s system $T$ by [9] Theorem 18.
Furthermore, the Gandy-Hyland functional is unique, i.e. \((\forall n^{0})(f(n) = g(n))\)', and the function \(g^{1}\) from \(\text{STP}\) is called a standard part of \(f^{1}\). Clearly, \(\text{STP}\) is a fragment of \textit{Standard Part}, while \(\Sigma_{2}^{0}\)-\text{TRANS} is a fragment of \textit{Transfer}. Proofs of the following theorem and corollary may be found in [34, §4.1].

\textbf{Theorem 5.1.} In \(P + \Sigma_{2}^{0}\)-TRANS + \(\text{STP}\), the Gandy-Hyland functional exists and equals its canonical approximation, i.e. there is standard \(\Gamma^{3}\) such that \(\text{GH}_{st}(\Gamma)\) and

\[(\forall Y^{2} \in C, s^{0})(\forall N \in \Omega)(G(Y, s, N) = \Gamma(Y, s)).\] (CA(\(\Gamma\))

Furthermore, the Gandy-Hyland functional is unique, i.e. \((\forall \Gamma^{3})(\text{GH}_{st}(\Gamma) \rightarrow \text{CA}(\Gamma))\).

To apply term extraction to Theorem 5.1, the following principles are needed.

\[(\forall Y^{2} \in C, f^{1}, g^{1})(\forall \Psi(Y, f) = \mu^{1}(Y, f) \rightarrow Y(f) = Y(g)).\] (MPC(\(\Psi\))

Note that \(\text{MPC}(\Psi)\) states that \(\Psi^{3}\) is a modulus-of-continuity functional, while \(\text{MU}(\mu)\) states that \(\mu^{2}\) is Feferman’s search operator (See e.g. [20] for the latter). We also need the following functional.

\[(\forall g^{2}, T^{1} \leq 1 1)((\forall \alpha^{1} \in \Theta(g)(2))(\alpha \leq 1 \rightarrow \alpha g(\alpha) \notin T) \rightarrow (\forall \beta \leq 1 1)(\exists i \leq 0 \Theta(g)(1))(\beta i \notin T)).\] (SCF(\(\Theta\))

The functional \(\Theta^{3}\) as in \(\text{SCF}(\Theta)\) is called the special fan functional, and its properties are discussed in Section 5.4. For now, it suffices to know that the special functional is part of classical and Brouwerian intuitionist mathematics. Note that there is no unique \(\Theta\) as in \(\text{SCF}(\Theta)\), i.e. it is in principle incorrect to talk about ‘the’ special fan functional. Finally, let \(\text{GH}(\Gamma)\) be \(\text{GH}\) with the leading quantifier omitted.

\textbf{Corollary 5.2 (Term Extraction).} From the proof in \(P\) of

\[\Sigma_{2}^{0}\)-TRANS + \(\text{STP}\) → \((\forall \Gamma^{3})(\text{GH}_{st}(\Gamma) \rightarrow \text{CA}(\Gamma))\], (5.3)

a term \(t^{4}\) can be extracted such that \(E\text{-PA}^{\omega*} + \text{QF-AC}^{1.0}\) proves that

\[(\forall \mu^{2}, \Theta^{3}, \Gamma^{3})(\text{GH}(\Gamma) \land \text{MU}(\mu) \land \text{SCF}(\Theta)) \rightarrow (\forall Y^{2} \in C, s^{0})(G(Y, s, t(Y, s, \mu, \Theta)) = \Gamma(Y, s))\],

i.e. \(G(Y, s, t(Y, s, \mu, \Theta))\) is the Gandy-Hyland functional expressed in terms of Feferman’s search operator and the special fan functional.

\[\text{Proof.}\] Apply \(\xi\) to the proof in Theorem 5.1.

Note that Feferman’s search operator can be defined in terms of a modulus-of-continuity functional (and vice versa) by combining the results in [20, §3], [10], and [21, §4]. Hence, we have the following:

\textbf{Corollary 5.3.} In the system from the previous corollary, the Gandy-Hyland functional can be expressed in terms of a modulus-of-continuity functional and the special fan functional.
5.3 Term extraction and \( \Gamma \), again

In this section, we show that the results of the previous section are rather modular, in that we may obtain variations of Theorem \( 5.1 \) and its corollaries. To this end, let \( \text{NPC}(Y) \) be the following formula:

\[
(\forall^s f^1)(\forall^s g^1)(f \eq_{1} g \rightarrow Y(f) =_0 Y(g)), \quad (\text{NPC}(Y))
\]

i.e. the previous formula expresses that \( Y^2 \in C \) is nonstandard continuous. Furthermore, let \( \text{ST} (\Gamma,Y) \) be \((\forall^s f^0)(\text{st}(\Gamma(Y,s))), \) i.e. \( \Gamma \) produces standard outputs, and let \( \text{GH}(\Gamma,Y) \) be \( \text{GH} \) with the two leading quantifiers omitted.

**Theorem 5.4.** The system \( P + \text{STP} \) proves that for all \( \Gamma^3 \) and \( Y^2 \)

\[
[\text{NSC}(Y) \land \text{GH}(\Gamma,Y) \land \text{ST} (\Gamma,Y)] \rightarrow (\forall^s f^0)(\forall N \in \Omega)(\Gamma(Y,s) = G(Y,s,N)). \quad (5.4)
\]

We need the following principles; Note that \( \text{PCM}(Y^2,Z^2) \) expresses that \( Z \) is a modulus of pointwise continuity for \( Y \).

\[
(\forall^s f^1,g^1)(\exists^s Z(f) =_0 \exists^s Z(g) \rightarrow Y(f) =_0 Y(g)) \quad (\text{PCM}(Y,Z))
\]

\[
(\forall^s f^0)[\Gamma(Y,s) = Y(s * 0 * \xi(\alpha \cdot n)) \land \Gamma(Y,s) \leq H(Y,s) \], \quad (\text{GHU}(\Gamma,Y,H))
\]

Applying \( \exists \mathcal{C} \) to the previous theorem, one obtains the following theorem.

**Corollary 5.5 (Term Extraction).** From the proof in Theorem \( 5.4 \) a term \( t \) can be extracted such that \( \text{E-PA}^{\omega^\omega} + \text{QF-AC}^{1,0} \) proves for \( \mathcal{E} = (H^1,Z^2,\Theta^3) \) and \( \Gamma^3,Y^2 \) that

\[
[\text{PCM}(Y,Z) \land \text{SCF}(\Theta) \land \text{GHU}(\Gamma,Y,H)] \rightarrow (\exists^s\forall N \geq t(s,\mathcal{E}))(\Gamma(Y,s) = G(Y,s,N)),
\]

i.e. the Gandy-Hyland functional \( \Gamma \) at \( Y \) can be approximated via a modulus of continuity of \( Y \), the special fan functional, and an upper bound for \( \Gamma(Y,\cdot) \).

5.4 The special fan functional

We discuss some surprising (computational and otherwise) properties of the special fan functional, which was first introduced in \[34, \S 3\].

First of all, the full axiom Transfer of IST does not imply the full axiom Standard Part (over various systems; see \[5,14\]). In this light, it is a natural question whether the same holds for prominent fragments discussed in this paper. For instance, are \( \Pi_1^0 \)-TRANS \( \rightarrow \text{STP} \) or \( \Pi_1^1 \)-TRANS \( \rightarrow \text{STP} \) provable in \( P \)?

Secondly, the previous questions can be translated into relative computability questions regarding the special fan functional and functionals like \( (\mu^2) \). We briefly discuss the answers to these questions from \[27\]. We need the following functionals.

\[
(\forall Y^2)(\forall f^1,g^1 \leq_1 1)(\exists^s \Phi(Y) =_0 \Phi(Y) \rightarrow Y(f) =_0 Y(g)). \quad (\text{MUC}(\Phi))
\]

\[
(\exists^s \xi^3)(\forall Y^2)[(\exists f^1)(Y(f) = 0) \leftrightarrow \xi^2(Y) = 0]. \quad (\varepsilon_2)
\]

The functional \( \Phi^3 \) as in \( \text{MUC}(\Phi) \) is called the intuitionistic fan functional and yields a conservative extension of weak König’s lemma for the second-order language (See \[20, \text{Prop. } 3.15\]). By the following theorems, the special fan functional is an object of intuitionistic and classical mathematics.
Theorem 5.6. There is a term $t$ such that $\text{E-PA}^\omega$ proves $(\forall \omega^2)(\mu \Omega(\omega) \rightarrow \text{SCF}(t(\omega)))$.

Theorem 5.7 (ZF). A functional $\Theta^3$ as in SCF$(\Theta)$ can be computed (Kleene's $\Sigma_1\Sigma_9$) from $\xi$ as in $\epsilon_2^3$.

Theorem 5.8 (ZF). Let $\phi^2$ be any type two functional. Any functional $\Theta^3$ as in SCF$(\Theta)$ is not computable (Kleene $\Sigma_1\Sigma_9$) in $\phi^2$.

Theorems 5.7 and 5.8 were first proved by Normann and are forthcoming in [27]. Theorem 5.8 for the special case of $(\mu^2)$ originates from the conjecture by the author that $\Pi^0_1$-TRANS does not imply STP over $P$. Since the Suslin functional is of type two, it cannot compute (Kleene $\Sigma_1\Sigma_9$) the special fan functional, which translates back to the fact that $P$ does not prove $\Pi^0_1$-TRANS $\rightarrow$ STP.

Acknowledgement 5.9. This research was supported by the following funding bodies: FWO Flanders, the John Templeton Foundation, the Alexander von Humboldt Foundation, the University of Oslo, and the Japan Society for the Promotion of Science. The author expresses his gratitude towards these institutions. The author would like to thank Grigori Mints, Ulrich Kohlenbach, Horst Osswald, Helmut Schwichtenberg, Stephan Hartmann, Dag Normann, and Karel Hrbacek for their valuable advice. Finally, I thank the anonymous referees for their many helpful suggestions.
