Abstract
A new genus, Xochiquetzallia, for the Brodiaeoideae, Asparagaceae family is here proposed. A taxonomic analysis based on morphology highlights its synapomorphies. The characters that distinguish Xochiquetzallia are the absence of a pith in the gynophore and the presence of an entire stigma. The recognition of Dandya purpusii as a monotypic genus is supported by the development of a short floral tube (< 2 mm) and a pith in the gynophore, as well as a divided stigma shared with the other genera of the Milla clade, Bessera, Jaimehintonia, Petronymphe and Milla. A key to its taxonomic determination is given for both the Xochiquetzallia species and the Milla clade genera.

Keywords
Asparagales, geophyte, gynophore, Mexico, Milla clade

Introduction
Dandya H.E. Moore is a genus endemic to Mexico and one of the five genera of the Milla clade (Gutiérrez et al. 2017). Dandya purpusii (Brandegee) H.E. Moore, the type species, has been placed in several genera in the past (Moore 1953) and molecular evidence suggest that generic limits in the complex are weak when few species are included in their phylogenetic analyses (Pires et al. 2001, Pires and Sytsma 2002, Gándara et al. 2014). Recently, Gutiérrez et al. (2017) conducted a study on the phylogeny of...
the *Milla* clade based on morphological, anatomical and molecular evidence (cDNA and ITS) and recovered two clades (Fig. 1). One clade recovers three species of *Dandya* plus *Milla mortoniana* strongly supported as sister to *Dandya purpusii* and the other four genera of the *Milla* clade (*Bessera, Jaimehintonia, Milla* and *Petronymphe*). Their results showed apomorphistic structural characters that support the genera. The analyses clarify the phylogenetic relationships of genera and species of the *Milla* clade. The most relevant outcome is that *Dandya* is paraphyletic where three species of *Dandya* with distribution in the Balsas River Basin share the same ancestor as *Milla mortoniana* (Fig. 1). These four species (*D. balsensis, D. hannibalii, D. thadhowardii* and *M. mortoniana*) have as a synapomorphy the entire stigma. The genus *Milla* is paraphyletic due to the exclusion of *Milla mortoniana*. The members of *Milla* share four synapomorphies (thin pedicel, floral tubes > 60 mm, anthers with a bicollateral bundle and 20-30% of the ovary adnate to the floral tube) not present in *M. mortoniana*. *Dandya purpusii* shares with *Bessera, Jaimehintonia, Milla* and *Petronymphe* the dissected stigma, but no other character is mentioned. Based on Gutiérrez et al. (2017) results, here we identify characters that are consistent with the phylogeny and create a new genus for the clade of *Dandya* and a *Milla* species, *Dandya* is circumscribed, and taxonomic keys are given that allow differentiating the genera of the *Milla* clade and the new genus.

**Material and methods**

Plant morphology was analyzed from field collected and herbarium material (ARIZ, BH, CHAPA, F, FC, GH, IEB, JEPS, MEXU, NY, RSA, UAMIZ, US and XAL). We studied the floral morphology from organisms collected in the field, except for *Milla mortoniana* (material removed from herbarium, MEXU). Morphological characters, vegetative and reproductive, were observed and analyzed with the help of a microscope (Nikon SMZ-2T) and terminology follows various authors (Moore 1953, Lenz 1971, Rahn 1998, Harris and Harris 2001). In addition, floral and foliar anatomical characters (Gutiérrez et al. 2010, 2015) were incorporated. The complete list of 60 characters and characters’ states used to delimit the monophyletic groups for the *Milla* complex can be consulted in Gutiérrez et al. (2017). Those characters that were recovered as synapomorphies or unique character combinations are here used to construct the keys for the *Milla* complex genera and the species of the new genus here proposed.

**Results**

Based on the phylogenetic clades recovered by Gutiérrez et al. (2017) and the deep morphological analysis of the species, we proposed the amended circumscription of *Dandya* and the new genus *Xochiquetzallia*. 
**Xochiquetzallia**, a new genus for Mexico and *Dandya* circumscription

**Figure 1.** Phylogenetic relationships of the *Milla* complex genera (modified from Gutiérrez et al. 2017).

**Taxonomic treatment**

*Dandya* H.E. Moore (1951)

**Diagnosis.** Perennial herbs, geophytic; terete; subcampanulate flowers, tube 1.5–3.0 mm long, erect; gynophore with pith, stigma divided.

*Dandya purpusii* (Brandegee) H.E. Moore

*Dandya purpusii* (Brandegee) H.E. Moore, Gent. Herb. 266–268 (1953).  
*Muilla purpusii* Brandegee, Univ. Calif. Publ. Bot. iv, 177 (1911).  
*Bloomeria purpusii* (Brandegee) Macbride, Contr. Gray Herb. Ser. 2. 56: 1-20 (1918).  
*Brodiaea purpusii* (Brandegee) Ingram, Madroño xii, 27 (1953).

**Description.** Perennial herbs, 28–47 cm tall, including corm and inflorescence. Fibrous roots. Corm subglobose compressed, fleshy, 1.0–1.7 cm in diameter; tunic formed by the wide bases of the leaves, brown or dark brown, covering up to 2.0 cm from the base of the scape. Leaves 2–3, 13–27 cm long, dark green, linear, subterete, with scabrous surface, hyaline prominences on the veins; base truncated, apex acute.
Inflorescence in umbel; Scape of 27–42 cm long, usually longer than leaves, terete, surface smooth or with acute prominences. Floral bracts 2–3, linear-lanceolate, triangular, 4.0–8.5 mm long; bracteoles, one per flower. Flowers 6–11, pedicels 2.0–4.0 cm long, subcampanulate, erect, articulate, floral tube 1.5–3.0 mm long; tepals blue, 6 in 2 series, external tepals ovate-lanceolate, 6.0–10.0 × 1.5–3.0 mm, apex acute and papillose, base cuneate, entire margin; internal tepals ovate-lanceolate, 6.0–9.5 × 1.6–3.0 mm, apex obtuse and papillose, base cuneate, entire margin. Stamens 6; filaments free, adnate to the throat of the tube, widened toward the base, 4.0–6.0 mm; anthers oblongs, yellow, basifix, 1.5–2.0 mm; gynophore 0.5–1.1 mm long, adnate to the floral perigone formed three cavities, present pith. Ovary cylindrical, 2.5–5.5 mm, fused at its base to the floral perigone; style filiform, 2.1–4.0 mm; stigma divided, papillose; capsule loculicidal, subcylindric, glabrous, brown, 10.0–12.0 mm long; seed oblong-falciform, compressed, black, bright, 3.0 × 5.0 mm.

Type species. MEXICO. Coahuila; Sierra de la Paila, October 1910, Purpus 4959 (holotype UC!; isotypes F!, GH!).

Specimen examined. MEXICO: Coahuila, Municipality of Ramos Arispe, Valle de los Ángeles, Sierra de la Paila, 6 August 1975, M. F. Robert & J. Passini 4675 (ENCB); El Cidral, Sierra de la Paila, 20 August 1987, J. A. Villarreal 3980 (TEX); 5.9 miles east of the road between Yucatan and Mexico, highway 40, west of the mountains along a gravel road to 17.2 miles north of Mexico highway 40, 1650 m elevation, 19 September 1996, J. M. Porter 11308 & J. T. Columbus (RSA); 15 km north of Estación Marte, on secondary road, 1550 m elevation, 24 October 2011, J. Gutiérrez et al. 1225 (FEZA, CHAPA, MEXU, UAMIZ).

Xochiquetzallia J.Gut., gen. nov.
urn:lsid:ipni.org:names:77204851-1
Fig. 2

Diagnosis. Perennial herbs, geophytic; terete or flattened leaves; subcampanulate or hypocrateriform flowers, tube 1.0–25.0 mm long, erect or reclined; gynophore without pith, stigma entire.

Description. Perennial herbs, 20–60 cm tall, including corm and inflorescence. Fibrous roots, some fleshy. Corm subglobose compressed, fleshy, 1.0–2.5 cm in diameter; tunic formed by the wide bases of the leaves, brown or dark brown, covering up to 2.0 cm from the base of the scape. Leaves 5–9, 20–49 cm long, dark green, linear, flattened or terete, with glabrous or scabrous surface, hyaline prominences on the veins; base truncated, apex acute. Inflorescence in umbel; Scape of (16–) 20–50 cm long, usually shorter than leaves, terete, surface smooth or with acute prominences. Floral bracts 2–3, linear-lanceolate, triangular, 3.0–9.0 mm long; bracteoles, one per flower. Flowers 4–20, pedicels 0.8–3.5 cm long, subcampanulate or hypocrateriform, erect or decumbent-descending, articulate, floral tube 1–25 mm long; tepals white or blue, 6 in 2 series, external tepals elliptic, 8.0–16.0 × (1.5–) 2.0–7.0 mm, 1–3 veins, apex acute.
Figure 2. Species of the genus Xochiquetzallia. A Xochiquetzallia mortoniana B X. hannibalii C X. bal-sensis D X. thadhowardii. A and B taken from the "Global Plants JSTOR".
and papillose, base cuneate, entire margin; internal tepals elliptical to broadly elliptical, (6.5–) 8.0–16.0 × (2.0–) 3.0–11.0 mm, apex obtuse and papillose, base cuneate, entire margin. Stamens 6; filaments free, adnate to the throat of the tube, widened toward the base or columnar, 2.0–5.0 (–7.0) mm; anthers linear, lanceolate-deltoid, yellow, basifixed, 1.0–2.5 mm; gynophore 0.8–1.6 mm long, adnate to the floral perigone formed three cavities. Ovary cylindrical, 1.0–5.0 mm, fused at its base to the floral perigone; style filament, 1.8–7.0 mm; stigma entire, papillose; capsule loculicidal, subglobose or subcylindric, glabrous, brown, 6.0–13.0 mm long; seed oblong-falciform, compressed, black, bright, seed coat papillose, 4.0 × 1.5 mm.

Type species. *Xochiquetzallia mortoniana* (H.E. Moore) J.Gut.

Etymology. This genus is named in honor of the goddess of Aztec flowers, in Nahua "Xochiquetzalli" (beautiful flower) "xóchitl" (flower), "quétzalli" (beautiful). The Aztecs developed majestic architectural works, had extensive knowledge of astronomy and great respect for nature, particularly plants.

Note

Xochiquetzallia balsensis (Dandya balsensis) and X. thadhowardii (D. thadhowardii) present morphological similarity and have a sympatric geographic distribution (Fig. 3). López-Ferrari and Espejo-Serna (1992) pointed out that Xochiquetzallia balsensis differs from X. thadhowardii by the size of the perigonium, filament and style segments, smaller in X. balsensis. Also, these authors indicate that in X. thadhowardii the anthers are firmly united among them around the style whereas in X. balsensis they are free. No differences in the morphological and anatomical characters were found between both species.
Xochiquetzallia, a new genus for Mexico and Dandya circumscription

The analysis carried out by Gutiérrez et al. (2017) shows that the population of the here proposed Xochiquetzallia balsensis from the state of Morelos is the only one that differentiates itself by the size of the filaments and the style as proposed by López-Ferrari and Espejo-Serna (1992). Based on our field observations in the type locality of Xochiquetzallia balsensis we confirm that their anthers are firmly united among them around the style as in X. thadhowardii and the separation of the anthers takes place in advanced stages of the anthesis, as occurs with X. thadhowardii. In this sense, it is concluded that Xochiquetzallia balsensis should be circumscribed by its filaments no larger than 3 mm long and less than or equal to 4 mm long.

**Discussion**

In Dandya and Xochiquetzallia, the connate stamens have been a recurrent character in the descriptions (Moore 1953; Lenz 1971; López-Ferrari and Espejo-Serna 1992). The staminal connation has been described as “crown or cup” at the base of the stamens and it was considered a diagnostic character for Dandya. Gutiérrez et al. (2010) did not find connate stamens in Dandya and Xochiquetzallia in their floral development study of the Milla complex. Moreover, they discovered that what was called “crown or cup” is the base of the filaments that is wider than the upper part and gives the appearance of detaching when the stamens are released asynchronously. Gutiérrez et al. (2010), also showed that Bessera is the only genus of the Milla clade that has connate filaments.
The existence of gynophore has also been a controversial feature. A gynophore was not described for the former species of *Dandya* now in *Xochiquetzallia* (*X. balsensis*, *X. hannibalii* and *X. thadhowardii*; Lenz 1971; López-Ferrari and Espejo-Serna 1992). Gutiérrez et al. (2010), when studying the gynophore, checked if it exists in the *Xochiquetzallia* species. They found that, unlike other genera of the *Milla* clade, the gynophore is short (< 2 mm) and lacks a pith. Also, *Xochiquetzallia balsensis*, *X. hannibalii* and *X. thadhowardii* have an entire stigma, a character shared with *X. mortoniana* which also lacks a pith in the gynophore. A recent study of floral anatomy of *Dandya purpusii*, allowed us to confirm that this species does have a pith in the gynophore as also found in *Bessera*, *Jaimehintonia*, *Milla* and *Petronymphe* (Gutiérrez et al. 2017). The short floral tube (< 2 mm) of *Dandya purpusii* was previously used as evidence to classify this species with the species of *Xochiquetzallia* (*Dandya*) (*X. balsensis*, *X. hannibalii* and *X. thadhowardii*) (Lenz 1971; López-Ferrari and Espejo-Serna 1992). However, the presence of the pith and the dissected stigma were not considered, and now we know both characters present in *Dandya purpusii* are shared with the other four genera. *Dandya purpusii* is distinguished by its ephemeral flowering and has been scarcely collected after its description in 1911 (Brandegee 1911). Further explorations in the distribution area of *Dandya purpusii*, now recognized as the only species of the genus *Dandya*, will hopefully reveal more localities and potentially the discovery of other species that are difficult to locate due to their ephemeral reproductive biology. The disjunct distribution between *Dandya purpusii* and the species of *Xochiquetzallia* suggests that both genera evolved independently and converged on floral shape as an adaptation to pollinators, among them the Lepidoptera.

Moore (1953) considered the floral shape as a discrete character that allowed to separate the genera of the *Milla* complex; for example, diagnostic floral shapes include subcampanulate for *Dandya*, tubular in *Petronymphe*, tubular and campanulate in *Bessera*, and hypocrateiform in *Jaimehintonia* and *Milla*. *Xochiquetzallia mortoniana* presents hypocrateiform flowers and this character allowed Moore (1953) to classify this species as *Milla*. Our investigations here found that *Bessera* species have all floral shape variations described in the genera of the clade (*Bessera tuitensis* has subcampanulate flowers, *B. elegans* campanulate, and *B. tenuiflora* tubular). The floral shapes among *Xochiquetzallia* species are either hypocrateiform or subcampanulate.

**Acknowledgments**

J. Gutiérrez thanks CONACYT for the grant awarded (160287) to perform doctoral studies. The authors also thank Ramiro Ríos Gómez and Eliseo Bravo Acevedo for their help in the field collection of the specimens studied and to Julio César Montero Rojas for artwork. The comments of a reviewer and the subject editor, Clifford Morden, are highly appreciated.
