ABSTRACT—Substance P (SP) binding protein of rat brain was solubilized by digitonin. The solubilized proteins were then purified by sequential gel filtration, concanavalin A lectin Sepharose, and SP-affinity chromatography. The calculated molecular weight of this purified SP binding protein was 76–74 kDa on sodium dodecyl sulfate-polyacrylamide gel electrophoresis. The rabbits were immunized with the purified protein and resulting polyclonal anti-sera were tested. The immune serum significantly inhibited [3H]SP binding to the 3-[3-cholamidopropyl]dimethyl ammonio]-1-propane sulfonate solubilized membrane fractions from rat brain, whereas pre-bleed antiserum failed to inhibit the binding. This polyclonal antibody also inhibited the activity of 45Ca influx into astroglia cells stimulated by SP, but does not inhibit that stimulated by histamine. Furthermore, this polyclonal antibody recognized the 76–74 kDa band as assessed by Western blotting. These data strongly suggest that this polyclonal antibody could recognize a part of the natural SP receptor site.

Keywords: Substance P, Binding protein, Brain (rat), Polyclonal antibody (substance P), Affinity chromatography (substance P)

Purification and characterization of the substance P (SP) receptor are important in understanding the molecular basis for the biological action between SP and its receptor. Unfortunately, there are no reports about the isolation of the SP receptor protein. However, the mRNA for the SP receptor was recently cloned and the amino acid sequence was determined (1). The molecular cloning and characterization of rat SP receptor have been reported by Hershey and Krause (2). The sequence showed the presence of N-glycosylation sites and hydrophobic membrane-spanning segments. The SP receptor belongs to the family of G-protein-coupled receptors and affects their functions by modulating inositol phosphate/calcium second messengers (3). The isolation of several other G-protein-coupled receptors, for example α- and β-adrenergic receptors and muscarine receptors, has been achieved by affinity chromatography. Therefore, the present study was designed to isolate SP binding protein with carbohydrate moieties by affinity chromatography and to make a polyclonal antibody for this protein. Using the polyclonal antibody, we could demonstrate a decrease in the SP-induced biological activity by covering the SP receptor with the polyclonal antibody.

MATERIALS AND METHODS

Membrane preparation and solubilization

Male Wistar rats (180–250 g) were used. Cerebral cortical membranes were prepared by the method of Nakata et al. (4). Immediately, after decapitation, the cerebral cortices were homogenized in ice-cold 0.32 M sucrose with a glass-Teflon homogenizer. Homogenates were centrifuged at 1,000 × g for 10 min to obtain the supernatants. These supernatants were then centrifuged at 17,000 × g for 20 min, and the pellets obtained were washed three times and used immediately for the solubilization experiments. For solubilization, the pellets were suspended in 50 mM Tris-HCl buffer containing 1% digitonin, 100 mM NaCl, 10 mM MgCl2 and 0.1 mM phenylmethyl sulfonyl fluoride (PMSF) at 4°C for 40 min. The final protein concentration during solu-
bilitation was approximately 5 mg/ml. After centrifuga-
tion of the solubilized mixture at 100,000 × g for 1 hr,
the supernatant was concentrated with an Amicon Cen-
triflo CF 25. The condensed supernatant was referred
to as the digitonin-solubilized fraction.

**[^3H]SP binding assay**

The binding assay was performed as described pre-
viously (4). Fresh membrane preparations were sus-
pended in assay buffer [50 mM Tris-HCl buffer (pH 7.4) containing 0.02% bovine serum albumin, 40 μg/ml bacitracin, 4 μg/ml leupeptin, 2 μg/ml chymostatin, 10 μM captopril and 10 mM MgCl₂]. A 50-μl aliquot of[^3H]SP was incubated at room temperature for 30 min with the membrane preparation in a final volume of 500 μl. Binding reactions were terminated by rapid filtra-
tion of the incubation mixture through a Whatman GF/B glass filter (presoaked with 0.1% poly-
ethyleneimine). Filters were washed four times with 10 ml of ice-cold 50 mM Tris-HCl buffer (pH 7.4). The
nonspecific binding of labeled ligand was determined with 3 μM unlabeled SP.

In the case of the solubilized fractions, the method
was modified slightly, with the incubation time and
temperature being 120 min and 0°C, respectively. Filtra-
tions were carried out using GF/B glass filters pre-
sosoaked with 0.3% polyethyleneimine according to the
method of Bruns et al. (5).

**Gel filtration**

The digitonin-solubilized fraction was applied to a
column of Sephadex G 75 (2.7 × 40 cm) previously
equilibrated with 0.01% digitonin, 10 mM MgCl₂ in 50
mM Tris-HCl buffer at 4°C. The column was eluted
with the same buffer at a flow rate of 6 ml/hr, and 2-ml
fractions were collected. Fractions were assayed for
binding activity by incubation with 1.0 nM[^3H]SP as
described above.

**Con A-Sepharose chromatography**

The combined fractions from Sephadex G-75 chroma-
tography were reacted batchwise with 100 ml of concan-
avalin A (Con A)-Sepharose gel, which had been
equilibrated with 50 mM Tris-HCl buffer containing
0.01% digitonin, 10 mM MgCl₂, and 2 mM CaCl₂ (Con
A buffer), and the gel suspension was stirred at 4°C for
2 hr. After washing with 500 ml of Con A buffer, 0.2 M
α-methylmannoside in Con A buffer was added to the
gel and incubated at 4°C for 2 hr to remove glycopro-
teins. After the incubation, the supernatant was con-
centrated and diluted with 50 mM Tris-HCl buffer.

**Affinity chromatography**

SP was coupled to epoxy-activated Sepharose 6B
(Pharmacia) according to the manufacturer’s directions.
The eluate from the Con A-Sepharose chromatography
as described above was loaded batchwise by continuous
shaking at 4°C for 2 hr with SP-Sepharose. The gel was
washed at 4°C with 100 volumes of 50 mM Tris-HCl
buffer containing 0.01% digitonin, 100 mM NaCl, and
10 mM MgCl₂. After the wash, 2 mM SP solution was
added to the gel and shaken at 4°C for 2 hr.

**Identification of glycoprotein as a SP receptor using
sodium dodecyl sulfate-polyacrylamide gel electro-
phoresis (SDS-PAGE)**

The eluate from Con A-Sepharose chromatography
was incubated with 2 nM SP at 0°C for 2 hr and then
covalently labeled by 50 μM disuccinimidyl suberate
(DSS), a bifunctional cross-linking reagent, to deter-
mine the apparent molecular weight according to a
slight modification of the method of Nakata et al. (6).
After the supernatant was concentrated and washed
distilled water to remove salts, the sample was
lyophilized. The lyophilized material was dissolved in
SDS-PAGE sample buffer (2% SDS, 15% glycerol,
0.0025% bromophenol blue, and 2.5% 2-mercaptoetha-
hol). Electrophoresis was performed according to the
method of Laemmli (7) using a 12% polyacrylamide
slab gel. After the electrophoresis, the gel was trans-
blotted onto a nitrocellulose filter using a Trans-Blot
SD (Bio-Rad). The filter was then incubated with rab-
bit anti-SP antibody (500-fold final dilution) in TBS
solution containing 3% gelatin at room temperature for
2 hr. After treatment, the nitrocellulose filter was
stained with a Vectastain ABC kit.

**Polyclonal antibody against the SP binding protein**

The proteins eluted by acetic acid from the final SP-
affinity chromatography were injected in a rabbit lymph
node in the presence of Freund’s adjuvant according to
the method of Sigel et al. (8). To boost the antibody
titers, the remaining proteins were implanted sub-
cutaneously four weeks later, and blood was withdrawn
10 days after this treatment.

**45Ca influx experiment**

The influx of 45 Ca was determined by the method of
Artalejo et al. (9). In brief, U-87 MG cells were cul-
tured for several days in Petri dishes (50 mm in diam-
eter). Before starting the influx experiment, the growth
medium was removed, and the cell layer was washed
with low potassium buffer that consisted of 140 mM
NaCl, 4.7 mM KCl, 1.2 mM KH₂PO₄, 1.2 mM MgSO₄,
1.2 mM CaCl₂, 11 mM glucose and 15 mM HEPES-Tris
The cells were stimulated with SP or histamine in the presence of $1 \mu$Ci $^{45}$CaCl$_2$, for 30 sec at 37°C. Cells were then washed 6 times with washing buffer (140 mM NaCl, 4.7 mM KCl, 3.7 mM MgCl$_2$, 2 mM EGTA, 2 mM LaCl$_2$, 11 mM glucose and 15 mM HEPES-Tris, pH 7.4). The radioactivity in the cells was determined in a liquid scintillation counter.

**Data analysis**

Significance of difference between the control and test values was determined by Student's t-test.

**Protein concentration determination**

Protein content was assayed by the method of Lowry et al. (10) with bovine serum albumin as the standard.

**Materials**

$[^{3}H]$Substance P (36.3 Ci/mmol) and $^{45}$Ca (8.53 mCi/mg) were purchased from NEN. Unlabeled SP was obtained from Peptide Institute, Inc. (Osaka, Japan). Bovine serum albumin, bacitracin, leupeptin, chymostatin, and Tris (hydroxymethyl)aminomethane were purchased from Sigma (St. Louis, MO). Polyethyleneimine and a-methyl-D-mannoside were from Nacalai Tesque, Inc. (Kyoto, Japan). Con A was from Boehringer Mannheim (Mannheim, Germany). Digitonin with a high solubility in water was from Wako Pure Chemicals (Osaka, Japan), and all other reagents were purchased from Nacalai Tesque, Inc. (Kyoto, Japan).

**RESULTS**

**Solubilization and purification of SP binding protein**

The SP binding site was solubilized from rat brain membranes with 1% digitonin. We have reported that SP binding protein could be solubilized by 3-[(3-cholamidopropyl) dimethylammonio]-1-propane sulfonate (CHAPS) (11). The $[^{3}H]$SP binding activity of the CHAPS-solubilized preparations decreased to less than 20% after 10 hr storage, even at 4°C. In the digitonin-solubilized preparation, $[^{3}H]$SP binding activity was stable for at least several days at 4°C. However, $[^{3}H]$SP binding activity was not observed while solubilizing proteins by 1% digitonin, but it could be detected just after the Sephadex G-75 gel permeation chromatography. This result indicates that a high concentration digitonin (in this case, 1% digitonin) interferes with the interaction of the SP receptor with $[^{3}H]$SP.

The digitonin-solubilized and condensed fraction was applied to a Sephadex G-75 column as described in Methods. We applied 105 mg solubilized protein/7 ml to a Sephadex G-75 column. Figure 1 shows a typical adsorption and SP binding activity profile. The activity

---

**Fig. 1.** Gel filtration chromatography of SP binding protein. The digitonin-solubilized fraction from rat brain was applied to the Sephadex G-75 column (2.7 X 40 cm) and eluted with 50 mM Tris-HCl buffer containing 0.01% digitonin and 10 mM MgCl$_2$. Fractions of 2 ml were collected at a flow rate of 6 ml/hr. The specific $[^{3}H]$SP binding activities and protein contents of these fractions were assayed. Blue dextran refers to the void volume. ○: $[^{3}H]$SP, ●: protein.
of \[^3H\]SP binding was broadly eluted with a void volume area. The fractions with \[^3H\]SP binding activity, usually fractions from 27 to 32, were pooled (approximately 30 mg protein). The combined fractions from Sephadex G-75 chromatography were mixed with Con A-Sepharose in a batchwise manner. The recovery of protein from Con A-Sepharose was approximately 1 mg protein, and the activity of \[^3H\]SP binding to the rat brain membranes was approximately 89 fmole. This fraction was subjected to SP-affinity chromatography. The fraction eluted from the affinity resin by the addition of 3 \(\mu\)M SP was subjected to SDS-PAGE, and then the proteins were detected by silver staining. Under the non-reduced condition, one major band with an apparent molecular mass of 76 kDa was present. When the sample was reduced by 50 mM dithiothreitol, this band migrated at 74 kDa (Fig. 2).

In the another series of experiments, to estimate the binding ability of these purified proteins, \[^{125}\text{I-Tyr}^8\]SP was used to elute proteins from the affinity resin. After that, the eluted fraction was divided into two samples; one was added to 3 \(\mu\)M SP and the other was added to water, and both were incubated for 2 hr at 4°C. After the incubation, each fraction was filtered by the method described above. According to this method, purified SP binding protein binds to 3.8 fmole \[^{125}\text{I-Tyr}^8\]SP and the recovery of the SP binding site was 0.16%. The estimated protein visualized by silver staining was approximately 0.2 ng according to the staining density; therefore, the specific activity was 19 nmole/mg protein. A summary of the purification of SP binding protein is shown in Table 1. An overall 1,370,000-fold purification of the SP binding protein was achieved by the three steps of different chromatographies.

**Immunological analysis of the SP binding protein**

In order to identify which protein(s) has an affinity to SP among the many glycoproteins trapped by...
Con A-Sepharose, we used DSS, a bifunctional crosslinking reagent, to make an irreversible association between the SP affinity protein(s) and SP by detecting bound SP using anti-SP antibody as described in Materials and Methods (6). Western blotting using the anti-SP antibody showed the specific labeling of a glycoprotein with an apparent molecular weight of 74 kDa (Fig. 3).

### Table 1. Purification of rat brain SP binding protein

|                | Total protein (mg) | Total activity (fmol) | Specific activity (fmol/mg) | Purification | Recovery (%) |
|----------------|--------------------|-----------------------|----------------------------|--------------|--------------|
| Membrane       | 176                | 2430                  | 13.8                       |              | 100          |
| Digitonin      | 122                | —                     | —                          |              |              |
| Sephadex G-75  | 30                 | 171                   | 5.7                        | 0.4          | 7.0          |
| Con A-Sepharose| 1.0                | 88.5                  | 88.5                       | 6.4          | 3.6          |
| SP-Sepharose   | 0.2*               | 3.8                   | 19,000                     | 1,376.00     | 0.16         |

*ng: the protein concentration in each band was estimated by comparing the densitometric tracing with a protein standard (bovine serum albumin) on SDS-PAGE.

Con A-Sepharose, we used DSS, a bifunctional crosslinking reagent, to make an irreversible association between the SP affinity protein(s) and SP by detecting bound SP using anti-SP antibody as described in Materials and Methods (6). Western blotting using the anti-SP antibody showed the specific labeling of a glycoprotein with an apparent molecular weight of 74 kDa (Fig. 3).

### Characteristics and properties of the anti-SP binding protein antibody

In order to further identify whether the 74-kDa glycoprotein was the SP binding protein, a rabbit was immunized with this protein, and the resulting polyclonal sera were tested by an inhibition of biological response induced by SP. First, the immune serum significantly inhibited 

\[^{3}H\]SP binding to the CHAPS solubilized fractions. At 100 dilution of the immune serum, the binding was reduced by approximately 50%, while at 1,000 dilution, the reduction was about 40% (Table 2).

Second, this immune serum inhibited the \(^{45}\)Ca influx into astroglia cell stimulated by SP. At 100 dilution of preimmune serum (blank serum), \(^{45}\)Ca influx stimu-

### Table 2. Effect of anti-SP binding protein antibody on \(^{3}H\)SP specific binding to the CHAPS-solubilized fractions from rat brain

| Dilution | \(^{3}H\)SP specific binding (\% of serum blank control) |
|----------|----------------------------------------------------------|
| 1 : 100  | 54.3 ± 6.1**                                             |
| 1 : 1,000| 62.2 ± 6.9*                                              |

The CHAPS-solubilized fractions from rat brain were incubated at 0 °C for 30 min with various concentrations of anti-SP binding protein antibody or the serum blank. \(^{3}H\)SP binding was determined as described under Materials and Methods. Serum alone did not influence \(^{3}H\)SP binding. All \(^{3}H\)SP values reported were calculated as a percentage of the serum blank binding value; i.e., the serum blank binding value was taken to be 100%. In the same preparation, the binding assay for dopamine D-1 receptors in the presence of anti-SP binding protein, to confirm its specificity, or the serum blank was performed as described previously (17). Both sera did not have any influence on the value of \(^{3}H\)SCH 23390 binding (98.5 ± 3.8% of the control at 100-fold dilution of anti-SP binding antibody). Each value shows the mean ± S.E.M. of five independent experiments. *P < 0.05, **P < 0.01 vs. control.

**Fig. 3.** Immunoblotting of rat brain SP binding protein. The Con A-Sepharose partially purified fraction was incubated with 3 μM SP and crosslinked with 50 μM DSS. These samples were subjected to SDS-PAGE on a 12% gel under the reducing condition, and electroblotted onto a nitrocellulose membrane. The membrane was incubated with rabbit anti-SP antibody. After the treatment, the membrane was stained with a Vectastain ABC kit.
lated by 1 μM SP and that by 10 μM histamine were approximately 1.51 ± 0.085-fold (n = 4) and 1.69 ± 0.11-fold (n = 4) those of the vehicle (buffer) stimulation, respectively. The pretreatment of the immune serum (final 100 dilution) with cells for one hour at 37°C inhibited the accumulation of 45Ca induced by 1 μM SP (86.1 ± 2.5% of the control, n = 4) without any effect on histamine-induced activity (189 ± 18% of the control, n = 4) (Fig. 4).

Fig. 4. Effects of anti-SP binding protein antibody on the 45Ca influx into human astroglialoma cells (U-87 MG) stimulated by SP or histamine. After pretreatment with anti-SP binding protein antibody for one hour at 37°C, the cells were incubated with/without 1 μM SP or 10 μM histamine in the 45Ca buffer for 30 sec at 37°C. The serum blank, when added to the cells kept in the low potassium buffer, had no influence on the value of 45Ca influx. Pretreatment of the cells with anti-SP binding protein antibody blocked stimulation of 45Ca influx by SP. Serum alone had no effect on 45Ca influx, nor did it inhibit 45Ca influx in response to SP or histamine. The value of 45Ca influx in the presence of serum was defined as the control. Each point shows the mean ± S.E.M. of 7-9 experiments. ** P < 0.01 vs. control, *** P < 0.001 vs. both sera.

DISCUSSION

In the present study, the SP binding protein from rat brain was solubilized with digitonin and then was purified with gel filtration and lectin chromatography, followed by SP affinity chromatography. We isolated 76 kDa material under the unreduced condition in SDS-PAGE. This protein may not include GTP-binding protein(s), since GTP binding proteins can be separated from glycoproteins by Con A-Sepharose chromatography.

Many neurotransmitter receptors have now been purified. In all cases, G-protein-linked receptors have been found to be composed of single unit. Significant sequence homologies are found among all G-protein-linked receptors, and they are translated into a conserved seven-transmembrane-spanning three-dimensional structure (12, 13). Another common structural feature of these receptors is related to the presence of potential N-linked glycosylation sites at the amino terminal (13). Glycosylation has been demonstrated to be essential to ensure the proper function and subcellular distribution of several surface glycoproteins; However, the precise role of glycosylation sites in membrane-bound receptors is still unknown. Our previous report demonstrated that the rat cortical SP receptor has either a biantennary complex-type or a high mannose-type of carbohydrate chain, and the carbohydrate chain is implicated in the SP binding activity of the SP receptor system (14). Similar results have recently been reported using porcine striatal membranes (15). To avoid the co-migration of other proteins which show an absent N-glycosylation sites like G-protein(s) in purification steps of SP binding protein, we harvested glycoproteins by lectin chromatography and estimated the molecular size of SP binding protein using DSS in these experiments (Fig. 3). Among the many glycoproteins which are trapped to Con A-Sepharose, the 76 kDa material is SP cross-linked by DSS. Therefore, it is possible that the 76-74 kDa glycoprotein is an SP receptor site containing various carbohydrate moieties.

The amino acid sequence of the rat SP receptor was already reported by Yokota et al. (1). SP receptor is composed of 407 amino acids residues with a relative molecular weight of 46,346 Da. The characteristics of this amino acid sequence of the SP receptor are: 1) shares many amino acid sequence features common to the G-protein-coupled receptor superfamily, 2) possesses the two potential N-glycosylation sites. Therefore, the molecular size of the native SP receptor should be larger than that of the protein itself. For example, the relative mobility of the striatal D2 receptors in the SDS-PAGE was changed from 94 kDa to about 43 kDa by treating the receptors with enzymes like exo- and/or endo-glycosidase. In the present experiment, since we used Con A lectin resin to isolate glycoproteins, it is not surprising that the molecular weight of the SP receptor determined here is different from that reported by Yokota et al. (1).

Recently, Oblas et al. (16) reported that during the course of an attempt to purify the SP receptor from horse salivary glands by SP affinity chromatography, they found a 78 kDa polypeptide that had an amino acid terminus identical to that of a glucose-regulated protein (GRP 78). This GRP 78 has no N-glycosylation
sites. Therefore, the 74 kDa SP binding protein we isolated is not identical to GRP 78, even though both are eluted from SP-affinity methods.

We have successfully raised a rabbit polyclonal antibody against 76–74 kDa SP binding protein by the intra-lymph node technique to inoculate rabbits with small quantities of antigen (8). Immunological experiments indicated that this polyclonal antibody recognized the 74 kDa glycoprotein from rat brain, which has a high affinity to SP. This polyclonal antibody also inhibited the specific SP binding and the activity of 45Ca influx into astroglia cells stimulated by SP. These data strongly suggest that 76–74 kDa SP binding protein is a critical component of the SP receptor or the receptor itself.

To further analyze the biochemical and pharmacological characteristics of the SP receptor, it will be important to determine the amino acid sequence of this purified SP binding protein, following by the cloning of the gene encoding this protein.
