Abstract

A poset can be regarded as a category in which there is at most one morphism between objects, and such that at most one of $\text{Hom}(c, c')$ and $\text{Hom}(c', c)$ is nonempty for $c \neq c'$. If we keep in place the latter axiom but allow for more than one morphism between objects, we can have a sort of generalized poset in which there are multiplicities attached to the covering relations, and possibly nontrivial automorphism groups. We call such a category an “updown category.” In this paper we give a precise definition of such categories and develop a theory for them, which incorporates earlier notions of differential posets and weighted-relation posets. We also give a detailed account of ten examples, including the updown categories of integer partitions, integer compositions, planar rooted trees, and rooted trees.

1 Introduction

Suppose we have a set $P$ of combinatorial objects, for example rooted trees, which naturally form a ranked poset (for rooted trees, the ranking is by the number of non-root vertices). Each object of $P$ can be constructed in steps from a basic object in rank 0, and $p$ covers $q$ in the partial order if $p$ can be built from $q$ in one step. (For rooted trees, the “basic object” is the one-vertex tree, and the building-up process consists of adding a new edge and terminal vertex to some existing vertex.) In this situation, there are naturally two sets of multiplicities on the covering relations of $P$: the number of ways to build up $p$ from $q$ is $u(q; p)$, and the number of ways to tear down $p$ to get $q$ is $d(q; p)$. (For example, for rooted trees $p, q$ with $p$ covering $q$, $u(q; p)$ is the number of distinct vertices of $q$ to which a new edge and terminal vertex can be added to get $p$, while $d(q; p)$ is the number of distinct terminal edges of $p$ that, when removed, leave $q$.) These multiplicities may
be distinct, as in the case of rooted trees (studied in detail in [4]), and the difference is related to the automorphism groups of objects of \( P \).

Now a poset can be thought of as a category with at most one morphism between objects, and at most one of the sets \( \text{Hom}(c, c') \) and \( \text{Hom}(c', c) \) nonempty when \( c \neq c' \). If we relax the the first of these conditions, we allow for multiplicities (if \( c \neq c' \)) and automorphisms (if \( c = c' \)). In §2 we give a precise definition of an updown category, which allows us to formalize the notions of the previous paragraph. We also define a morphism between updown categories, as well as products of updown categories. For any updown category \( \mathcal{C} \), we define “up” and “down” operators \( U \) and \( D \) on the free vector space \( k(\text{Ob}\mathcal{C}) \), \( k \) a field of characteristic 0.

In [3] a theory of universal covers was developed for weighted-relation posets, i.e., ranked posets in which each covering relation has a single number \( n(x, y) \) assigned to it. The universal cover of a weighted-relation poset \( P \) is the “unfolding” of \( P \) into a usually much larger weighted-relation poset \( \tilde{P} \), so that the Hasse diagram of \( \tilde{P} \) is a tree and all covering relations of \( \tilde{P} \) have multiplicity 1. Although the description of \( \tilde{P} \) had a natural description in each of the seven examples considered in [3], the general construction of \( \tilde{P} \) given in [3, Theorem 3.3] was somewhat unsatisfactory since it involved many arbitrary choices. In §3 we study unilateral updown categories (i.e., updown categories with trivial automorphism groups): these are essentially “categorified” weighted-relation posets, and the universal-cover construction (Proposition 3.3 below) is much more natural in this setting.

In [10, 11] Stanley developed a theory of differential posets. Some ideas of this theory were extended to the case of rooted trees in [4]. In §4 we offer a more general view of “commutation conditions” that may be satisfied by the operators \( U \) and \( D \) defined in §2 for any updown category.

The theory developed here is somewhat similar to Fomin’s theory of duality of graded graphs [12], but is both more restrictive and more general: more restrictive in that the functions \( u(p; q) \) and \( d(p; q) \) must give rise to the same partial order, i.e., for any pair \( p, q \) we have \( u(p; q) = 0 \) if and only if \( d(p; q) = 0 \); and more general in that we consider weaker commutation conditions than he does.

In §5 we offer ten examples, which include all those given in [3]. These include the posets of monomials, necklaces, integer partitions, integer compositions, and both planar rooted trees and rooted trees.

The basic idea of this paper was conceived during the academic year 2002-2003, when the author was partially supported by the Naval Academy Research Council. This paper was written during a stay at the Max-Planck-Institut für Mathematik during the following academic year, while the author was on sabbatical leave from the Naval Academy. The author thanks both the Academy and the Institut for their support.

2 Updown categories

We begin by defining an updown category.
Definition 2.1. An updown category is a small category \( \mathcal{C} \) with a rank functor \( | \cdot | : \mathcal{C} \to \mathbb{N} \) (where \( \mathbb{N} \) is the ordered set of natural numbers regarded as a category) such that

A1. Each level \( \mathcal{C}_n = \{ p \in \text{Ob} \mathcal{C} : |p| = n \} \) is finite.

A2. The zeroth level \( \mathcal{C}_0 \) consists of a single object \( \hat{0} \), and \( \text{Hom}(\hat{0}, p) \) is nonempty for all objects \( p \) of \( \mathcal{C} \).

A3. For objects \( p, p' \) of \( \mathcal{C} \), \( \text{Hom}(p, p') \) is always finite, and \( \text{Hom}(p, p') = \emptyset \) unless \( |p| < |p'| \) or \( p = p' \). In the latter case, \( \text{Hom}(p, p) \) is a group, denoted \( \text{Aut}(p) \).

A4. Any morphism \( p \to p' \), where \( |p'| = |p| + k \), factors as a composition \( p = p_0 \to p_1 \to \cdots \to p_k = p' \), where \( |p_{i+1}| = |p_i| + 1 \);

A5. If \( |p'| = |p| + 1 \), the actions of \( \text{Aut}(p) \) and \( \text{Aut}(p') \) on \( \text{Hom}(p, p') \) (by precomposition and postcomposition respectively) are free.

Given an updown category, we can define the multiplicities mentioned in the introduction as follows.

Definition 2.2. For any two objects \( p, p' \) of an updown category \( \mathcal{C} \) with \( |p'| = |p| + 1 \), define

\[
u(p; p') = |\text{Hom}(p, p')/\text{Aut}(p')| = \frac{|\text{Hom}(p, p')|}{|\text{Aut}(p')|}\]

and

\[
d(p; p') = |\text{Hom}(p, p')/\text{Aut}(p)| = \frac{|\text{Hom}(p, p')|}{|\text{Aut}(p)|}.
\]

It follows immediately from these definitions that

\[
u(p; p')|\text{Aut}(p')| = d(p; p')|\text{Aut}(p)|.
\] (1)

We note two extreme cases. First, suppose \( \mathcal{C}_n \) is empty for all \( n > 0 \). Then \( \mathcal{C} \) is essentially the finite group \( \text{Aut}(\hat{0}) \). Second, suppose that every set \( \text{Hom}(p, p') \) has at most one element. Then \( \mathcal{C} \) is a ranked poset with least element \( \hat{0} \).

Two important special types of updown categories are defined as follows

Definition 2.3. An updown category \( \mathcal{C} \) is unilateral if \( \text{Aut}(p) \) is trivial for all \( p \in \text{Ob} \mathcal{C} \). An updown category \( \mathcal{C} \) is simple if \( \text{Hom}(c, c') \) has at most one element for all \( c, c' \in \text{Ob} \mathcal{C} \), and the factorization in A4 is unique, i.e., for \( |c'| > |c| \) any \( f \in \text{Hom}(c, c') \) has a unique factorization into morphisms between adjacent levels.

Of course simple implies unilateral, but not conversely. A unilateral updown category is the “categorification” of a weighted-relation poset in the sense of \([3]\); see the next section for details.

If \( \mathcal{C} \) and \( \mathcal{D} \) are updown categories, their product \( \mathcal{C} \times \mathcal{D} \) is the usual one, i.e. \( \text{Ob}(\mathcal{C} \times \mathcal{D}) = \text{Ob} \mathcal{C} \times \text{Ob} \mathcal{D} \) and

\[
\text{Hom}_{\mathcal{C} \times \mathcal{D}}((c, d), (c', d')) = \text{Hom}_\mathcal{C}(c, c') \times \text{Hom}_\mathcal{D}(d, d').
\]

The rank is defined on \( \mathcal{C} \times \mathcal{D} \) by \( |(c, d)| = |c| + |d| \). We have the following result.
Proposition 2.1. If $\mathcal{C}$ and $\mathcal{D}$ are updown categories, then so is their product $\mathcal{C} \times \mathcal{D}$.

Proof. Since

$$(\mathcal{C} \times \mathcal{D})_n = \coprod_{i+j=n} \mathcal{C}_i \times \mathcal{D}_j,$$

axiom A1 is clear; and evidently $\hat{0} = (\hat{0}_\mathcal{C}, \hat{0}_\mathcal{D})$ satisfies A2. Checking A3 is routine, and for A4 we can combine factorizations

$$c = c_0 \to c_1 \to \cdots \to c_k = c' \quad \text{and} \quad d = d_0 \to d_1 \to \cdots \to d_l = d'.$$

into

$$(c, d) \to (c_1, d) \to \cdots \to (c', d) \to (c', d_1) \to \cdots \to (c', d').$$

Finally, for A5 note that, e.g.,

$$\text{Hom}((c, d), (c', d)) \cong \text{Hom}(c, c') \times \text{Aut}(d),$$

and the action of $\text{Aut}(c, d) \cong \text{Aut}(c) \times \text{Aut}(d)$ on this set is free if and only if the action of $\text{Aut}(c)$ on $\text{Hom}(c, c')$ is free. \qed

We note that the product of two unilateral categories is unilateral, but the product of simple categories need not be simple: see Example 2 in §5 below. We now define a morphism of updown categories.

Definition 2.4. Let $\mathcal{C}, \mathcal{D}$ be updown categories. A morphism from $\mathcal{C}$ to $\mathcal{D}$ is a functor $F : \mathcal{C} \to \mathcal{D}$ with $|F(p)| = |p|$ for all $p \in \text{Ob} \mathcal{C}$, and such that, for any $p, q \in \text{Ob} \mathcal{C}$ with $|q| = |p| + 1$, the induced maps

$$\text{Aut}(p, p) \to \text{Aut}(F(p), F(p)),$$

$$\coprod_{\{q' : F(q') = F(q)\}} \text{Hom}(p, q')/\text{Aut}(p) \to \text{Hom}(F(p), F(q))/\text{Aut}(F(p)),$$

and

$$\coprod_{\{q' : F(q') = F(q)\}} \text{Hom}(p, q')/\text{Aut}(q') \to \text{Hom}(F(p), F(q))/\text{Aut}(F(q))$$

are injective.

We have the following result.

Proposition 2.2. Suppose $F : \mathcal{C} \to \mathcal{D}$ is a morphism of updown categories. If $\mathcal{D}$ is unilateral, then so is $\mathcal{C}$; if $\mathcal{D}$ is simple, then $\mathcal{C}$ is also simple and $F$ is injective as a function on object sets.

Proof. It follows immediately from Definition 2.4 that $\mathcal{C}$ must be unilateral when $\mathcal{D}$ is.

Now suppose $\mathcal{D}$ is simple. Then $\mathcal{C}$ is unilateral, and it follows from Definition 2.4 that the induced function

$$\coprod_{\{q' : F(q') = F(q)\}} \text{Hom}(p, q') \to \text{Hom}(F(p), F(q))$$

are injective.

We have the following result.
is injective when $|q| = |p| + 1$: but $\text{Hom}(F(p), F(q))$ is (at most) a one-element set, so $F$ must be injective on object sets and $\text{Hom}(p, q)$ can have at most one object. But then unique factorization of morphisms in $\mathcal{C}$ follows from that in $\mathcal{D}$, so $\mathcal{C}$ is simple.

One can verify that there is a morphism of updown categories $\mathcal{C} \to \mathcal{C} \times \mathcal{D}$ given by sending $c \in \text{Ob} \mathcal{C}$ to $(c, \hat{0}_\mathcal{D})$ whenever $\mathcal{C}$ and $\mathcal{D}$ are updown categories; similarly there is a morphism $\mathcal{D} \to \mathcal{C} \times \mathcal{D}$. We denote the $n$-fold cartesian power of $\mathcal{C}$ by $\mathcal{C}^n$.

Let $\mathbb{k}$ be a field of characteristic 0, $\mathbb{k}(\text{Ob} \mathcal{C})$ the free vector space on $\text{Ob} \mathcal{C}$ over $\mathbb{k}$. We now define “up” and “down” operators on $\mathbb{k}(\text{Ob} \mathcal{C})$.

**Definition 2.5.** For an updown category $\mathcal{C}$, let $U, D : \mathbb{k}(\text{Ob} \mathcal{C}) \to \mathbb{k}(\text{Ob} \mathcal{C})$ be the linear operators given by

$$U p = \sum_{|p'| = |p| + 1} u(p; p') p'$$

and

$$D p = \begin{cases} \sum_{|p'| = |p| - 1} d(p'; p)p', & |p| > 0, \\ 0, & p = \hat{0}, \end{cases}$$

for all $p \in \text{Ob} \mathcal{C}$.

**Proposition 2.3.** The operators $U$ and $D$ are adjoint with respect to the inner product on $\mathbb{k}(\text{Ob} \mathcal{C})$ defined by

$$\langle p, p' \rangle = \begin{cases} |\text{Aut}(p)|, & \text{if } p' = p, \\ 0, & \text{otherwise}. \end{cases}$$

**Proof.** Since $\langle Up, p' \rangle = \langle p, Dp' \rangle = 0$ unless $|p'| = |p| + 1$, it suffices to consider that case. Then

$$\langle Up, p' \rangle = u(p; p') \langle p', p' \rangle = u(p; p') |\text{Aut}(p')|$$

while

$$\langle p, Dp' \rangle = d(p; p') \langle p, p \rangle = d(p; p') |\text{Aut}(p)|,$$

and the two agree by equation (1).

Now we extend the definitions of $u(p; p')$ and $d(p; p')$ to any pair $p, p' \in \text{Ob} \mathcal{C}$ by setting $u(p; p') = d(p; p') = 0$ if $\text{Hom}(p, p') = \emptyset$ and

$$u(p; p') = \frac{\langle U^{[p'] - |p|}(p), p' \rangle}{|\text{Aut}(p')|}, \quad d(p; p') = \frac{\langle U^{[p'] - |p|}(p), p' \rangle}{|\text{Aut}(p)|}$$

otherwise. It is immediate that equation (1) still holds, and that

$$U^k(p) = \sum_{|p'| = |p| + k} u(p; p') p'$$

and

$$D^k(p) = \sum_{|p'| = |p| - k} d(p; p') p'$$
for any $p \in \text{Ob } \mathcal{C}$. (However, it is no longer true that $u(p; q)$ and $d(p; q)$ have any simple relation to $|\text{Hom}(p, q)|$ when $|q| - |p| > 1$.) An important special case of the extended equation (1) is

$$\frac{d(\hat{0}; p)}{u(\hat{0}; p)} = \frac{|\text{Aut}(p)|}{|\text{Aut} \hat{0}|}$$

(2)

for any object $p$ of $\mathcal{C}$. If $\text{Aut} \hat{0}$ is trivial (as in all the examples of §5 below), equation (2) gives the order of the automorphism group of $p \in \text{Ob } \mathcal{C}$ as a ratio of multiplicities (cf. Proposition 2.6 of [4]). We also have the following result.

**Proposition 2.4.** If $|p| \leq k \leq |q|$, then

$$u(p; q) = \sum_{|p'| = k} u(p; p')u(p'; q),$$

and similarly for $u$ replaced by $d$.

**Proof.** We have

$$u(p; q) = \frac{\langle U^{q-|p|} p, q \rangle}{|\text{Aut}(q)|}$$

$$= \frac{1}{|\text{Aut}(q)|} \langle U^{k-|p|} U^{q-|p|} (p), q \rangle$$

$$= \frac{1}{|\text{Aut}(q)|} \sum_{|p'| = k} u(p; p') \langle U^{k-|p|} p', q \rangle$$

$$= \frac{1}{|\text{Aut}(q)|} \sum_{|p'| = k} u(p; p')u(p'; q)|\text{Aut}(q)|$$

$$= \sum_{|p'| = k} u(p; p')u(p'; q),$$

and the proof for $d$ is similar. \qed

**Definition 2.6.** For an updown category $\mathcal{C}$, define the induced partial order on $\text{Ob } \mathcal{C}$ by setting $p \preceq q$ if and only if $\text{Hom}(p, q) \neq \emptyset$.

It follows from Proposition 2.4 that $p \preceq q \iff u(p; q) \neq 0 \iff d(p; q) \neq 0$. Henceforth we write $p \prec q$ if $q$ covers $p$ in the induced partial order.

In the unilateral case, equation (2) is trivial since $u(p; q) = d(p; q)$ for all $p$ and $q$. Nevertheless, we have the following interpretation of the multiplicity in this case.

**Proposition 2.5.** Let $\mathcal{C}$ be a unilateral updown category, $p, q \in \text{Ob } \mathcal{C}$ with $|q| - |p| = n > 0$. Then $u(p; q) = d(p; q)$ is the number of distinct chains $(h_1, \ldots, h_n)$ so that each $h_i$ is a morphism between adjacent levels and $h_n h_{n-1} \cdots h_1$ is a morphism from $p$ to $q$.
Proof. We use induction on $n$. The result is immediate if $n = 1$, since in a unilateral updown category

$$u(p; q) = d(p; q) = |\text{Hom}(p, q)|$$

when $|q| = |p| + 1$. Now if $N(p, q)$ denotes the number of chains $(h_1, \ldots, h_n)$ as in the statement of the proposition, it is evident that, for $|q| > |p| + 1$,

$$N(p, q) = \sum_{r < q} N(p, r)N(r, q).$$

But then the inductive step follows from Proposition 2.4.

\[\square\]

3 Weighted-Relation Posets and Unilateral Updown Categories

Let $\mathfrak{U}$ be the category of updown categories, $\mathfrak{U}_u$ the full subcategory of unilateral updown categories. For a functor $F$ between unilateral updown categories $\mathcal{C}$, $\mathcal{D}$, Definition 2.4 reduces to the requirement that $F$ preserve rank and that the induced function

$$\bigoplus_{\{q': F(q') = F(q)\}} \text{Hom}(p, q') \to \text{Hom}(F(p), F(q))$$

be injective whenever $p, q \in \text{Ob} \mathcal{C}$ with $|q| = |p| + 1$.

The notion of a weighted-relation poset was defined in [3]. This consists of a ranked poset

$$P = \bigcup_{n \geq 0} P_n$$

with a least element $\hat{0} \in P_0$, together with nonnegative integers $n(x, y)$ for each $x, y \in P$ so that $n(x, y) = 0$ unless $x \preceq y$, and

$$n(x, y) = \sum_{|z| = k} n(x, z)n(z, y)$$

whenever $|x| \leq k \leq |y|$. A morphism of weighted-relation posets $P, Q$ is a rank-preserving map $f : P \to Q$ such that

$$n(f(t), f(s)) \geq \sum_{s' \in f^{-1}(f(s))} n(t, s')$$

for any $s, t \in P$ with $|s| = |t| + 1$. Let $\mathfrak{W}$ be the category of weighted-relation posets.

Given an updown category $\mathcal{C}$, it follows from Proposition 2.4 that the weight functions $n(x, y) = u(x; y)$ and $n(x, y) = d(x; y)$ on the poset $\text{Ob} \mathcal{C}$ (with the partial order defined by Definition 2.6) both satisfy equation (4). So we have two weighted-relation posets based on $\text{Ob} \mathcal{C}$ corresponding to these two sets of weights. In fact, we can describe them functorially.
If $\mathcal{C}$ is an updown category, we can form a unilateral updown category $\mathcal{C}^\uparrow$ with $\text{Ob} \mathcal{C}^\uparrow = \text{Ob} \mathcal{C}$, and with $\text{Hom}_{\mathcal{C}^\uparrow}(p, p')$ defined as follows. We declare $\text{Hom}_{\mathcal{C}^\uparrow}(p, p) = \text{Aut}_{\mathcal{C}^\uparrow}(p)$ trivial for all $p$, and for $|p'| > |p|$ we define $\text{Hom}_{\mathcal{C}^\uparrow}(p, p')$ to be the set $\text{Hom}_{\mathcal{C}}(p, p')$ with the equivalence relation generated by declaring, for any factorization $f = f_n f_{n-1} \cdots f_1$ of $f \in \text{Hom}_{\mathcal{C}}(p, p')$ into morphisms between adjacent levels, $f$ equivalent to $\alpha_n f_n \cdots \alpha_1 f_1$, where $\alpha_i \in \text{Aut}(\text{trg} f_i)$. It is routine to check that $\mathcal{C}^\uparrow$ satisfies the axioms of an updown category, and for $p, p' \in \text{Ob} \mathcal{C}$ with $|p'| = |p| + 1$ the multiplicity is

$$|\text{Hom}_{\mathcal{C}^\uparrow}(p, p')| = |\text{Hom}_{\mathcal{C}}(p, p')/ \text{Aut}_{\mathcal{C}}(p')| = u(p; p').$$

Of course $\mathcal{C}^\uparrow$ coincides with $\mathcal{C}$ if $\mathcal{C}$ is unilateral.

Similarly, for any updown category $\mathcal{C}$ there is a unilateral updown category $\mathcal{C}^\downarrow$ with $\text{Ob} \mathcal{C}^\downarrow = \text{Ob} \mathcal{C}$, trivial automorphisms, and $\text{Hom}_{\mathcal{C}^\downarrow}(p, p')$ the set $\text{Hom}_{\mathcal{C}}(p, p')$ with the equivalence relation $f \sim f_n \beta_n f_{n-1} \cdots f_1 \beta_1$ for $f = f_n f_{n-1} \cdots f_1$ a factorization of $f \in \text{Hom}_{\mathcal{C}}(p, p')$ into morphisms between adjacent levels and $\beta_i \in \text{Aut}(\text{src} f_i)$. Then

$$|\text{Hom}_{\mathcal{C}^\downarrow}(p, p')| = |\text{Hom}_{\mathcal{C}}(p, p')/ \text{Aut}_{\mathcal{C}}(p)| = d(p; p')$$

for $p, p' \in \text{Ob} \mathcal{C}$ with $|p'| = |p| + 1$. We have the following result.

**Proposition 3.1.** There are two functors $\mathfrak{U} \to \mathfrak{U} \downarrow$, taking an updown category $\mathcal{C}$ to $\mathcal{C}^\uparrow$ and $\mathcal{C}^\downarrow$ respectively.

**Proof.** We first consider the “up” functor. For a morphism $F : \mathcal{C} \to \mathcal{D}$ of updown categories, we must produce a morphism $F^\uparrow : \mathcal{C}^\uparrow \to \mathcal{D}^\uparrow$ of unilateral updown categories. But given such a functor $F$, Definition 2.4 requires that $F$ preserve rank and that the induced function

$$\bigoplus_{\{q' : F(q') = F(q)\}} \text{Hom}(p, q')/ \text{Aut}(p') \to \text{Hom}(F(p), F(q))/ \text{Aut}(F(q))$$

be injective for all $p, q \in \text{Ob} \mathcal{C}$ with $|q| = |p| + 1$. This is exactly the statement that the induced functor $F^\uparrow$ is a morphism of unilateral updown categories. The proof for the “down” functor is similar. \qed

Now we pass from unilateral updown categories to weighted-relation posets.

**Proposition 3.2.** There is a functor $\text{Wrp} : \mathfrak{U} \to \mathfrak{U} \downarrow$, sending a unilateral updown category $\mathcal{C}$ to the set $\text{Ob} \mathcal{C}$ with the partial order of Definition 2.5 and the weight function $n(x, y) = u(x; y) = d(x; y)$.

**Proof.** The only thing to check is the morphisms. Suppose $F : \mathcal{C} \to \mathcal{D}$ is a morphism of $\mathfrak{U} \downarrow$. Then $F$ defines a function on the object sets, and the function $[\ ]$ is injective. Hence

$$\sum_{\{q' : F(q') = F(q)\}} |\text{Hom}(p, q')| \leq |\text{Hom}(F(p), F(q))|$$

and so (since, e.g., $n(p, q') = |\text{Hom}(p, q')|$), inequality $[\ ]$ holds and $F$ induces a morphism of weighted-relation posets. \qed
As defined in [3], a morphism $f : P \to Q$ of weighted-relation posets is a covering map if $f$ is surjective and the inequality [4] is an equality. A universal cover $\widetilde{P}$ of $P$ is a cover $\widetilde{P} \to P$ such that, if $P' \to P$ is any other cover, then there is a covering map $\widetilde{P} \to P'$ so that the composition $\widetilde{P} \to P' \to P$ is the cover $\widetilde{P} \to P$. In [3] such a universal cover was constructed for any weighted-relation poset $P$.

In fact, the construction of [3] can be made considerably simpler and more natural if we work instead with unilateral updown categories. We first categorify the definition of covering map.

**Definition 3.1.** A morphism $\pi : \mathcal{C}' \to \mathcal{C}$ of unilateral updown categories is a covering map if $\pi$ is surjective on the object sets and the induced function

$$\prod_{\{q' : \pi(q') = \pi(q)\}} \text{Hom}(p, q') \to \text{Hom}(\pi(p), \pi(q))$$

is a bijection for all $p, q \in \text{Ob} \mathcal{C}'$ with $|q| = |p| + 1$.

Then we have the following result.

**Proposition 3.3.** Every unilateral updown category $\mathcal{C}$ has a universal cover $\widetilde{\mathcal{C}}$.

**Proof.** We define $\widetilde{\mathcal{C}}$ to be the category whose level-$n$ objects are strings $(f_1, f_2, \ldots, f_n)$ of morphisms $f_i \in \text{Hom}(c_{i-1}, c_i)$, where $c_i \in \mathcal{C}_i$, and whose morphisms are just inclusions of strings. It is straightforward to verify that $\widetilde{\mathcal{C}}$ is a unilateral updown category (with $\emptyset_\mathcal{C}$ the empty string). Define the functor $\pi : \widetilde{\mathcal{C}} \to \mathcal{C}$ by sending the empty string to $\emptyset \in \text{Ob} \mathcal{C}$, the nonempty string $(f_1, \ldots, f_n)$ of $\widetilde{\mathcal{C}}$ to the target of $f_n$ in $\text{Ob} \mathcal{C}$, and the inclusion $(f_1, \ldots, f_j) \subset (f_1, \ldots, f_n)$ to the morphism $f_j f_{n-1} \cdots f_1 \in \text{Hom}(c_j, c_n)$. That the induced function (6) is a bijection is a tautology.

Now let $P : \mathcal{C}' \to \mathcal{C}$ be another cover of $\mathcal{C}$: we must define a covering map $F : \widetilde{\mathcal{C}} \to \mathcal{C}'$ of unilateral updown categories so that $\pi = P F$. We proceed by induction on level: evidently we can get started by sending the empty string in $\widetilde{\mathcal{C}}_0$ to the element $\emptyset$ of $\mathcal{C}'$. Suppose $F$ is defined through level $n-1$, and consider a level-$n$ object $(f_1, \ldots, f_n)$ of $\widetilde{\mathcal{C}}$. Let $c_n = \pi(f_1, \ldots, f_n)$. By the induction hypothesis we have $c_{n-1}' = F(f_1, \ldots, f_{n-1}) \in \text{Ob} \mathcal{C}'$, and $c_n = P(c_{n-1}')$ is the target of $f_n$, hence the source of $f_n$. Since

$$P : \prod_{\{c' : p(c') = c_n\}} \text{Hom}(c_{n-1}', c') \to \text{Hom}(c_{n-1}, c_n)$$

is a bijection, there is a unique morphism $g$ of $\mathcal{C}'$ with src$(g) = c_{n-1}'$ sent to $f_n : c_{n-1} \to c_n$. We define $F(f_1, \ldots, f_n)$ to be $\text{trg}(g)$, and the image of the inclusion of $(f_1, \ldots, f_{n-1})$ in $(f_1, \ldots, f_n)$ to be $g$. This actually defines the functor $F$ through level $n$, since by the induction hypothesis $F$ assigns to the inclusion of any proper substring $(f_1, \ldots, f_k)$ in $(f_1, \ldots, f_{n-1})$ a morphism $h$ from $F(f_1, \ldots, f_k)$ to $c_{n-1}'$ in $\mathcal{C}'$; then $F$ sends the inclusion of $(f_1, \ldots, f_k)$ in $(f_1, \ldots, f_n)$ to $gh$. \qed
Remark. If we think of the functor $\pi : \tilde{C} \to C$ as a function on the object sets, then the number of objects of $\tilde{C}$ that $\pi$ sends to $p \in \text{Ob} C$ is $u(0; p) = d(0; p)$: this follows from Proposition 2.5.

The construction of $C$ in the preceding result is functorial: given a morphism $F : C \to D$ of unilateral updown posets, we have a morphism $\tilde{F} : \tilde{C} \to \tilde{D}$ given by

$$\tilde{F}(f_1, f_2, \ldots, f_n) = (F(f_1), F(f_2), \ldots, F(f_n)).$$

Also, the updown category $C$ is evidently simple. Thus, if $\mathcal{SU}$ is the full subcategory of simple updown categories in $\mathcal{U}$, then there is a functor $\mathcal{SU} \to \mathcal{SU}$ taking $C$ to $\tilde{C}$. In fact, we have the following result.

**Proposition 3.4.** The functor $\mathcal{SU} \to \mathcal{SU}$ taking $C$ to $\tilde{C}$ is right adjoint to the inclusion functor $\mathcal{SU} \to \mathcal{SU}$.

**Proof.** It suffices to show that

$$\text{Hom}_{\mathcal{SU}}(C, D) \cong \text{Hom}_{\mathcal{SU}}(C, \tilde{D})$$

for any simple updown category $C$ and unilateral updown category $D$. A morphism $F : C \to D$ of unilateral updown categories gives rise to $\tilde{F} : \tilde{C} \to \tilde{D}$, and since $C$ is simple there is a natural identification $C \cong \tilde{C}$, giving us a morphism $C \to \tilde{D}$. To go back the other way, just compose with the covering map $\pi : \tilde{D} \to D$. \qed

## 4 Commutation Conditions

We shall consider various conditions on the commutator of the operators $D$ and $U$ introduced in §2. In what follows we write $P_i$ for the restriction of the operator $P$ to level $i$, so $[D, U]_i = D_{i+1}U_i - U_{i-1}D_i$.

**Definition 4.1.** Let $C$ be an updown category, with operators $D$ and $U$ as defined above. We write $I$ for the identity operator on $\mathbb{k}(\text{Ob} C)$.

1. If $[D, U] = rI$, where $r$ is a scalar, then $C$ satisfies the absolute commutation condition (ACC) with constant $r$.

2. If $[D, U]_i = (ai + b)I_i$ for constants $a, b$ then $C$ satisfies the linear commutation condition (LCC) with slope $a$.

3. If $[D, U]_i = r_iI_i$ for some sequence of scalars $\{r_0, r_1, \ldots\}$, then $C$ satisfies the sequential commutation condition (SCC).

4. If every element of $\text{Ob} C$ is an eigenvector for $[D, U]$, then $C$ satisfies the weak commutation condition (WCC).
Evidently ACC ⇒ LCC ⇒ SCC ⇒ WCC. We can rephrase the preceding definition as follows. The updown category $\mathcal{C}$ satisfies the WCC if there is a function $\epsilon : \text{Ob} \mathcal{C} \to k$ such that $(DU - UD)(c) = \epsilon(c)c$ for all $c \in \text{Ob} \mathcal{C}$. Then $\mathcal{C}$ satisfies the ACC if $\epsilon(c)$ is independent of $c$, the LCC if $\epsilon(c)$ is a linear function of $|c|$, and the SCC if $\epsilon(c)$ is an arbitrary function of $|c|$. We have the following result about products; cf. Lemma 2.2.3 of [2].

Proposition 4.1. Let $\mathcal{C}$ and $\mathcal{D}$ be updown categories.

1. If $\mathcal{C}$ satisfies the ACC with constant $r$ and $\mathcal{D}$ satisfies the ACC with constant $s$, then $\mathcal{C} \times \mathcal{D}$ satisfies the ACC with constant $r + s$.

2. If $\mathcal{C}$ and $\mathcal{D}$ satisfy the LCC with slope $a$, then so does $\mathcal{C} \times \mathcal{D}$.

3. If $\mathcal{C}$ and $\mathcal{D}$ satisfy the WCC, then so does $\mathcal{C} \times \mathcal{D}$.

Proof. Since any element of $\mathcal{C} \times \mathcal{D}$ covering $(c, d) \in \text{Ob} \mathcal{C} \times \mathcal{D}$ must have the form $(c', d)$ with $c'$ covering $c$ or $(c, d')$ with $d'$ covering $d$, we have

$$U(c, d) = \sum_{|c'| = |c| + 1} u(c; c')(c', d) + \sum_{|d'| = |d| + 1} u(d; d')(c, d') = (Uc, d) + (c, Ud),$$

and similarly for $D$. If $\mathcal{C}$ and $\mathcal{D}$ satisfy the WCC, we can calculate that

$$(DU - UD)(c, d) = ((DU - UD)c, d) + (c, (DU - UD)d) = (\epsilon(c) + \epsilon(d))(c, d),$$

from which all three parts follow easily. \qed

The following result generalizes Proposition 2.4 of [4].

Proposition 4.2. Let $\mathcal{C}$ be an updown category satisfying the WCC, and define $\epsilon : \text{Ob} \mathcal{C} \to k$ as above. Then for objects $c_1, c_2$ of $\mathcal{C}$,

$$\langle U(c_1), U(c_2) \rangle - \langle D(c_1), D(c_2) \rangle = \begin{cases} 0, & \text{if } c_1 \neq c_2; \\ \epsilon(c)|\text{Aut}(c)|, & \text{if } c_1 = c_2 = c. \end{cases}$$

Proof. Calculate using the adjointness of $U$ and $D$. \qed

Remark. The second alternative of this result can be written

$$\sum_{c' \succ c} u(c; c')^2 |\text{Aut}(c')| - \sum_{c'' \preceq c} d(c''; c)^2 |\text{Aut}(c'')| = \epsilon(c)|\text{Aut}(c)|,$$

or, dividing by $|\text{Aut}(c)|$ and using equation (11),

$$\sum_{c' \succ c} u(c; c')d(c; c') - \sum_{c'' \preceq c} u(c''; c)d(c''; c) = \epsilon(c). \quad (7)$$
In an updown category satisfying the SCC, we can obtain the kinds of results proved by Stanley for sequentially differential posets [11] and by Fomin for r-graded graphs in [2]. For example, we have the following result by essentially the same proof as Theorem 2.3 of [11] (see also Proposition 2.7 of [4]).

**Proposition 4.3.** Let $C$ be an updown category satisfying the SCC, and let $p \in C_k$. Call a word $w = w_1w_2 \cdots w_s$ in $U$ and $D$ a valid $p$-word if the number of $U$’s minus the number of $D$’s in $w$ is $k$, and, for each $1 \leq i \leq s$, the number of $D$’s in $w_i \cdots w_s$ does not exceed the number of $U$’s. For such a word $w$, let $S = \{i : w_i = D\}$ and

$$c_i = |\{j : j > i, w_j = U\}| - |\{j : j \geq i, w_j = D\}|, \quad i \in S.$$

Then for any valid $p$-word $w$,

$$\langle w^0, p \rangle = d(\hat{0}; p) \prod_{i \in S} (r_0 + r_1 + \cdots + r_{c_i}).$$

This result has the following corollary (cf. [4, Proposition 2.8] and [2, Theorem 1.5.2]).

**Proposition 4.4.** Let $C$ be an updown category satisfying the SCC, and let $p \in C_k$. Then for nonnegative $a$,

$$\sum_{|q|=k+a} d(p; q)u(\hat{0}; q) = u(\hat{0}; p) \prod_{i=0}^{a-1} (r_0 + r_1 + \cdots + r_{k+i}).$$

**Proof.** Set $w = D^aU^{a+k}$ in the preceding result to get

$$\langle D^aU^{a+k}\hat{0}, p \rangle = d(\hat{0}; p) \prod_{i=0}^{a-1} (r_0 + r_1 + \cdots + r_{k+i}).$$

Expand out the left-hand side to get

$$\sum_{|q|=k+a} u(p; q)d(\hat{0}; q) = d(\hat{0}; p) \prod_{i=0}^{a-1} (r_0 + r_1 + \cdots + r_{k+i}).$$

Now use equation (11) and divide by $|\text{Aut } p|/|\text{Aut } \hat{0}|$ to obtain the conclusion. \qed

In the case $p = \hat{0}$ the preceding result is

$$\sum_{|q|=a} d(\hat{0}; q)u(\hat{0}; q) = \prod_{i=0}^{a-1} (r_0 + r_1 + \cdots + r_i). \quad (8)$$

Comparable results in the case where $C$ merely satisfies the WCC appear to be much more complicated. From equation (7) we have

$$\sum_{|q|=1} u(\hat{0}; q)d(\hat{0}; q) = e(\hat{0}), \quad (9)$$

12
generalizing the case $a = 1$ of equation (8). Since $\epsilon(\hat{0})\hat{0} = (DU - UD)\hat{0} = DU\hat{0}$, it follows that $(DU)^n\hat{0} = (\epsilon(\hat{0}))^n\hat{0}$ for all $n$. We use this in proving the following result, which generalizes cases $a = 2$ and $a = 3$ of equation (8).

**Proposition 4.5.** If $\mathcal{C}$ satisfies the WCC, then

$$
\sum_{|q|=2} u(\hat{0}; q)d(\hat{0}; q) = \epsilon(\hat{0})^2 + \sum_{|p|=1} u(\hat{0}; p)d(\hat{0}; p)\epsilon(p)
$$

$$
\sum_{|t|=3} u(\hat{0}; t)d(\hat{0}; t) = \sum_{|p|=1} u(\hat{0}; p)d(\hat{0}; p)(\epsilon(p) + \epsilon(0))^2 + \sum_{|q|=2} u(\hat{0}; q)d(\hat{0}; q)\epsilon(q).
$$

**Proof.** For the first part, write $D^2U^2 = (DU)^2 + D[D, U]U$ and apply it to $\hat{0}$:

$$
\langle D^2U^2\hat{0}, \hat{0} \rangle = \langle (DU)^2\hat{0}, \hat{0} \rangle + \sum_{|p|=1} \langle u(\hat{0}, p)D[D, U]p, \hat{0} \rangle
$$

$$
= (\epsilon(\hat{0}))^2 \langle \hat{0}, \hat{0} \rangle + \sum_{|p|=1} \langle u(\hat{0}, p)\epsilon(p)Dp, \hat{0} \rangle
$$

$$
= (\epsilon(\hat{0}))^2 |\text{Aut} \hat{0}| + \sum_{|p|=1} u(\hat{0}; p)\epsilon(p)d(\hat{0}; p)|\text{Aut} \hat{0}|.
$$

On the other hand,

$$
\langle D^2U^2\hat{0}, \hat{0} \rangle = \langle U^2\hat{0}, U^2\hat{0} \rangle = \sum_{|q|=2} \sum_{|p|=2} u(\hat{0}; p)u(\hat{0}; q)\langle p, q \rangle = \sum_{|q|=2} u(\hat{0}; q)^2|\text{Aut}(q)|
$$

and the first part follows using equation (11).

To prove the second part, start by applying

$$
D^3U^3 = D^2[D, U]U^2 + DUD[D, U]U + D[D, U]^2U + D[D, U]U DU + (DU)^3
$$

to $\hat{0}$ and proceed similarly, making use of equation (9). $\square$

## 5 Examples

In this section we present ten examples of updown posets. Many of the associated weighted-relation posets appear in the last section of [3]. For the convenience of the reader we have included a cross-reference to [3] at the beginning of each example where it applies.

**Example 1.** Let $\mathcal{C}$ be an updown category such that $\mathcal{C}_1$ consists of a single object $\hat{1}$, $\mathcal{C}_n = \emptyset$ for $n \neq 0, 1$, and $\text{Hom}(\hat{0}, \hat{1})$ has a single element. The groups $\text{Aut}(\hat{0})$ and $\text{Aut}(\hat{1})$ are trivial since they act freely on the one-element set $\text{Hom}(\hat{0}, \hat{1})$. Then

$$(DU - UD)\hat{0} = D\hat{1} = \hat{0},$$

13
and

$$(DU - UD) \hat{\mathcal{C}} = -U\hat{0} = -\hat{1},$$

so $\mathcal{C}$ satisfies the LCC with slope $-2$. Of course $\mathcal{C}$ is simple.

**Example 2. (Subsets of a finite set; [3 Example 1])** Let $\mathcal{D} = \mathcal{C}^n$, where $\mathcal{C}$ is the updown category of Example 1. There is an identification of objects of $\mathcal{D}$ with subsets of $\{1, 2, \ldots, n\}$: an $n$-tuple $(c_1, \ldots, c_n)$ corresponds to the set $\{i : c_i = \hat{1}\}$. The induced partial order is inclusion of sets, and for $|p'| = |p| + 1$ we have

$$u(p; p') = d(p; p') = \begin{cases} 1, & \text{if } p \text{ is a subset of } p', \\ 0, & \text{otherwise}. \end{cases}$$

The category $\mathcal{D}$ is unilateral, but not simple for $n \geq 2$. In [3] it is shown that the universal cover $\tilde{\mathcal{D}}$ is the simple updown category whose level-$m$ elements are linearly ordered $m$-element subsets of $\{1, \ldots, n\}$, and whose morphisms are inclusions of initial segments. From Proposition 4.1, $\mathcal{D}$ satisfies the LCC with slope $-2$; in fact, it is easy to see that $(DU - UD)p = (n - 2|p|)p$ for any object $p$ of $\mathcal{D}$.

**Example 3.** Let $\mathcal{C}$ be the category with $\mathcal{C}_n = \{[n]\}$, where $[n] = \{1, 2, \ldots, n\}$ (and $[0] = \emptyset$), and let $\text{Hom}([m], [n])$ be the set of injective functions from $[m]$ to $[n]$. Then the axioms are easily seen to hold, with $\text{Aut}[n] = \Sigma_n$ (the symmetric group on $n$ letters). Since $\text{Hom}([n], [n+1])$ has $(n+1)!$ elements, we have $u([n]; [n+1]) = 1$ and $d([n]; [n+1]) = n+1$. More generally, we have $u([n]; [m]) = 1$ and $d([n]; [m]) = m!/n!$ for $m \geq n$. The unilateral updown poset $\mathcal{C}^\uparrow$ is just the infinite chain $\mathbb{N}$ regarded as a simple updown category. On the other hand, a morphism of $\mathcal{C}^\uparrow$ from $[n]$ to $[n+1]$ can be thought of as an element of $[n+1]$ (the element that a representative injective function $[n] \to [n+1]$ misses), and so a level-$n$ object of $\mathcal{C}^\uparrow$ can be identified with a chain $(i_1, i_2, \ldots, i_n)$ of positive integers with $i_j \leq j$.

We have $U([n]) = [n] + 1$ and $D([n]) = n[n-1]$, so

$$(DU - UD)([n]) = (n+1)[n] - n[n] = [n],$$

and thus $\mathcal{C}$ satisfies the ACC with constant $1$. Cf. Example 2.2.1 of [2].

**Example 4. (Monomials; [3 Example 2])** Let $\mathcal{D} = \mathcal{C}^n$, where $\mathcal{C}$ is the updown category of Example 3. Objects of $\mathcal{D}$ can be identified with monomials in $n$ commuting indeterminates $t_1, \ldots, t_n$. The automorphism group of $t_1^{i_1} t_2^{i_2} \cdots t_n^{i_n}$ is $\Sigma_{i_1} \times \Sigma_{i_2} \times \cdots \times \Sigma_{i_n}$, and a monomial $u$ precedes a monomial $v$ in the induced partial order if $u$ is a factor of $v$. We have

$$u(1; t_1^{i_1} \cdots t_n^{i_n}) = \frac{(i_1 + \cdots + i_n)!}{i_1! \cdots i_n!} \quad \text{and} \quad d(1; t_1^{i_1} \cdots t_n^{i_n}) = (i_1 + \cdots + i_n)!.$$

The weighted-relation poset $\text{Wrp}(\mathcal{D}^\uparrow)$ appears in [3], where it is shown that the universal cover $\tilde{\mathcal{D}}$ can be identified with the simple updown category whose objects are monomials in $n$ noncommuting indeterminates $T_1, \ldots, T_n$, and whose morphisms are inclusions as left factors. From Proposition 4.1, $\mathcal{D}$ satisfies the ACC with constant $n$. Cf. Example 2.2.2 of [2].
Example 5. (Necklaces; Example 3) For a fixed positive integer $c$, let $N_m$ be the set of $m$-bead necklaces with beads of $c$ possible colors. More precisely, a level-$m$ object of $N$ is an equivalence class of functions $f : \mathbb{Z}/m\mathbb{Z} \to [c]$, where $f$ is equivalent to $g$ if there is some $n$ so that $f(a+n) = g(a)$ for all $a \in \mathbb{Z}/m\mathbb{Z}$. Thus, for $c = 2$ the equivalence class
\[
\{(1, 1, 2, 2), (2, 1, 1, 2), (2, 2, 1, 1), (1, 2, 2, 1)\}
\]
represents the necklace $\bigcirc$.

A morphism from the equivalence class of $f$ in $N_m$ to the equivalence class of $g$ in $N_n$ is an injective function $h : \mathbb{Z}/m\mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$ with $f(a) = gh(a)$ for all $a \in \mathbb{Z}/m\mathbb{Z}$, and such that $h$ preserves the cyclic order, i.e., if we pick representatives of the $h(i)$ in $\mathbb{Z}$ with $0 \leq h(i) \leq n-1$, then some cyclic permutation of $(h(0), h(1), \ldots, h(m-1))$ is an increasing sequence.

In Example 1.6.8 it is shown that the universal cover $\tilde{D}$ of the weighted-relation poset $\text{Wrp}(N^\circ)$ is constructed as the set of necklaces with labelled beads. It is also shown that for $p \in N_m$, $u(\hat{0}, p) = \frac{m!}{|\text{Aut}(p)|}$.

Example 6. (Integer partitions with unit weights; Example 5) Let $\mathcal{Y}$ be the category with $\text{Ob} \mathcal{Y}$ the set of integer partitions, i.e., finite sequences $(\lambda_1, \lambda_2, \ldots, \lambda_k)$ of positive integers with $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_k$.

The level of a partition is $|\lambda| = \lambda_1 + \lambda_2 + \cdots + \lambda_k$; we write $\ell(\lambda)$ for the length (number of parts) of $\lambda$. The set of morphisms $\text{Hom}(\lambda, \mu)$ contains a single element if and only if $\lambda_i \leq \mu_i$ for all $i$. Then $\mathcal{Y}$ is evidently unilateral but not simple. The weights $u(\lambda; \mu) = d(\lambda; \mu)$ appear in the ring of symmetric functions: we have
\[
s_1^k s_\lambda = \sum_{|\mu|=|\lambda|+k} u(\lambda; \mu) s_\mu
\]
where $s_\mu$ is the Schur symmetric function associated with the partition $\mu$ (for definitions see [2]). In Example 3 it is shown that the universal cover $\tilde{\mathcal{Y}}$ is the poset of standard Young tableaux, so $u(\hat{0}; \lambda) = d(\hat{0}; \lambda)$ is the number of standard Young tableaux of shape $\lambda$.

That $\mathcal{Y}$ satisfies the ACC with constant 1 is shown in Corollary 1.4, where $\mathcal{Y}$ is the motivating example of theory of differential posets; $\mathcal{Y}$ also appears as Example 1.6.8 of [2].
Example 7. Let \( \mathcal{K} \) be the category with \( \text{Ob} \mathcal{K} \) the set of integer partitions, and \( \text{Hom}(\lambda, \mu) \) defined as follows. Let \( \lambda = (\lambda_1, \ldots, \lambda_n) \) and \( \mu = (\mu_1, \ldots, \mu_m) \), always written in decreasing order. Then a morphism from \( \lambda \) to \( \mu \) is an injective function \( f : [n] \to [m] \) such that \( \lambda_i \leq \mu_i \) whenever \( f(i) = j \).

The partial order induced on \( \text{Ob} \mathcal{K} = \text{Ob} \mathcal{Y} \) is the same as that of the preceding example: the difference is that we now have nontrivial automorphism groups and weights on covering relations. The automorphism group of \( \lambda = (\lambda_1, \ldots, \lambda_k) \) is the subgroup of \( \Sigma_k \) consisting of those permutations \( \sigma \) such that \( \lambda_i = \lambda_j \) whenever \( \sigma(i) = j \). For a partition \( \lambda \), let \( m_k(\lambda) \) be the number of times \( k \) occurs in \( \lambda \). Then for partitions \( \lambda, \mu \) with \( |\mu| = |\lambda| + 1 \), we can describe the weights explicitly as

\[
u(\lambda; \mu) = \begin{cases} 1, & \text{if } \mu \text{ is obtained from } \lambda \text{ by adding a new part of size } 1, \\ m_k(\lambda), & \text{if } \mu \text{ is obtained by increasing a part of size } k \text{ in } \lambda \text{ to } k + 1, \\ 0, & \text{otherwise.} \end{cases}
\]

\[
d(\lambda; \mu) = \begin{cases} m_1(\mu), & \text{if } \mu \text{ is obtained from } \lambda \text{ by adding a new part of size } 1, \\ m_{k+1}(\mu), & \text{if } \mu \text{ is obtained increasing a part of size } k \text{ in } \lambda \text{ to } k + 1, \\ 0, & \text{otherwise.} \end{cases}
\]

The weights \( d(\lambda; \mu) \) appear implicitly in [6] and explicitly in [5], where they are referred to as “Kingman’s branching”: see especially Figure 4 of [5]. As noted there, the \( d(\lambda; \mu) \) have an algebraic interpretation similar to that of the last example: in the ring of symmetric functions we have

\[
m_k^{\lambda} m_\lambda = \sum_{|\mu|=|\lambda|+k} d(\lambda; \mu) m_\mu,
\]

where \( m_\lambda \) is the monomial symmetric function associated with \( \lambda \).

The universal cover \( \hat{\mathcal{K}}^+ \) can be described in terms of set partitions: in fact, we can identify elements of \( \hat{\mathcal{K}}^+_n \) with partitions of \([n]\) so that the covering map \( \pi : \hat{\mathcal{K}}^+ \to \mathcal{K}^+ \) takes a partition \( P \) of \([n]\) to the integer partition of \( n \) given by the block sizes of \( P \). Actually we will identify elements of \( \hat{\mathcal{K}}^+_n \) with ordered partitions \( (P_1, \ldots, P_k) \) of \([n]\), where

\[
|P_1| \geq |P_2| \geq \cdots \geq |P_k|
\]

and, if \( |P_i| = |P_j| \) for \( i < j \), \( \max P_i < \max P_j \). We do this by using the construction of Proposition 3.3. Assign the unique partition of \([1]\) to the morphism from \( \hat{0} \) to \( \hat{1} \), and suppose inductively that we have assigned an ordered partition \( P = (P_1, \ldots, P_k) \) of \([n]\) to the chain \((h_1, \ldots, h_n)\) of morphisms between adjacent levels of \( \mathcal{K}^+ \) from \( \hat{0} \) to \( \text{trg}(h_n) = (\lambda_1, \ldots, \lambda_k) \in \text{Ob} \mathcal{K}^+_n \) so that \( \lambda_i = |P_i| \). Let \( f \in \text{Hom}_\mathcal{K}(\lambda, \mu) \) be a representative of the equivalence class \( h_{n+1} \in \text{Hom}_{\hat{\mathcal{K}}^+}(\lambda, \mu) \), where \( |\mu| = n+1 \). If \( \mu \) has length \( k+1 \), there is a unique element \( i \in [k+1] \) not in the image of \( f \); in this case assign \((P_1, \ldots, P_k, \{n+1\})\) to the chain \((h_1, \ldots, h_n, h_{n+1})\). Otherwise, \( \mu \) has length \( k \) and there is a unique \( i \in [k] \) such that \( \lambda_i < \mu_{f(i)} \); in this case, assign to \((h_1, \ldots, h_{n+1})\) the rearrangement of \((P'_1, \ldots, P'_k)\), where

\[
P'_j = \begin{cases} P_j \cup \{n+1\}, & \text{if } j = i, \\ P_j, & \text{otherwise}, \end{cases}
\]
so that $P'_h$ immediately follows $P'_m$, where $m = \max\{j < i : |P'_j| \geq |P'_i|\}$. Evidently the set partition assigned to $(h_1, \ldots, h_{n+1})$ projects to $\mu$ in either case.

Level-$n$ objects of the universal cover $\hat{\mathcal{K}}_\updownarrow$ can be described as sequences $s = (a_1, \ldots, a_n)$ such that $m_1(s) \geq m_2(s) \geq \cdots$, where $m_s(s)$ is the number of occurrences of $i$ in $s$; the covering map sends $s$ to $(m_1(s), m_2(s), \ldots)$. As in the preceding paragraph, we can proceed inductively using the construction of Proposition 3.3. Start by assigning $s = (1)$ to the morphism from $0$ to $(1)$. Suppose now we have assigned $s = (a_1, \ldots, a_n)$ to a chain of morphisms $(h_1, \ldots, h_n)$ between adjacent levels of $\mathcal{K}_\updownarrow$ from $0$ to $\lambda = (\lambda_1, \ldots, \lambda_k) \in \mathcal{K}_n^\updownarrow$ so that $m_i(s) = \lambda_i$ for $1 \leq i \leq k$, and let $h_{n+1} \in \text{Hom}_{\mathcal{K}_\updownarrow}(\lambda, \mu)$ where $|\mu| = n + 1$. Now a representative $f \in \text{Hom}_{\mathcal{K}_\updownarrow}(\lambda, \mu)$ of $h_{n+1}$ must be “almost an automorphism” exchanging parts of equal size with just one exception: there is a unique $i \in [\ell(\mu)]$ such that either $i$ is not in the image of $f$ (in which case $\mu_i = 1$), or else $\lambda_{f-1(i)} < \mu_i$ (in which case $\mu_i = \lambda_{f-1(i)} + 1$). Let $S = \{j > i : \lambda_{f-1(j)} = \mu_i\}$; note that $S$ is independent of the choice of $f$. Now define a permutation $\sigma$ of $[\ell(\mu)]$ as follows. If $S = \emptyset$, let $\sigma$ be the identity; otherwise, if $S = \{i + 1, \ldots, l\}$, let $\sigma(a) = a + 1$ for $i \leq a \leq l - 1$, $\sigma(l) = i$, and $\sigma(a) = a$ for $a \notin \{i, \ldots, l\}$. We then assign the sequence $s' = (\sigma(a_1), \ldots, \sigma(a_k), i)$ to the chain $(h_1, \ldots, h_n, h_{n+1})$. If $i \notin \text{im} f$, then $\mu_j = 1$ for $j \geq i$ and either $i = \ell(\mu) = k + 1$ (if $S$ is empty) or $l = \ell(\mu) = k + 1$ (if it isn’t): either way $\mu$ differs by $\lambda$ by having $1$ inserted in the $i$th position, and $s'$ projects to $\mu$. If $\mu_i = \lambda_{f-1(i)} + 1$, then we must have $\lambda_j = \mu_j$ for $j < i$, and $\mu$ differs from $\lambda$ in having a part of size $\mu_i - 1$ increased by $1$. If $S$ is empty, $\lambda_{f-1(i)} = \lambda_i$ and $\mu_i = m_i(s') = m_i(s) + 1 = \lambda_i + 1$. Otherwise, $\mu_i = m_i(s') = m_i(s) + 1 = \lambda_{f-1(i)}$ and $m_{i+1}(s') = m_j(s)$ for $i \leq j \leq l - 1$. Either way, $s'$ again projects to $\mu$.

The updown poset $\mathcal{K}$ satisfies the WCC with $\epsilon(\lambda) = 1 + m_1(\lambda)$. That is,

$$(DU - UD)(\lambda) = (1 + m_1(\lambda))\lambda$$

(10)

for all partitions $\lambda$. To prove this, we introduce the union operation on partitions, e.g., $(2, 1) \cup (3, 1, 1) = (3, 2, 1, 1, 1)$. If we extend $\cup$ linearly to $\mathcal{K}(\text{Ob} \mathcal{K})$, then it is straightforward to show that

$$D(\lambda \cup \mu) = D(\lambda) \cup \mu + \lambda \cup D(\mu)$$

$$U(\lambda \cup \mu) = U(\lambda) \cup \mu + \lambda \cup U(\mu) - \lambda \cup \mu \cup (1)$$

for partitions $\lambda, \mu$. An easy calculation then shows

$$(DU - UD)(\lambda \cup \mu) = (DU - UD)(\lambda) \cup \mu + \lambda \cup (DU - UD)(\mu) - \lambda \cup \mu,$$

and since $m_1(\lambda \cup \mu) = m_1(\lambda) + m_1(\mu)$, equation (10) must hold for $\lambda \cup \mu$ whenever it holds for $\lambda$ and $\mu$. Since (10) is easy to show for partitions with one part, the general result follows by induction on length.

**Example 8.** (Integer compositions; [3] Example 6) Let $\mathcal{C}_n$ be the set of integer compositions of $n$, i.e. sequences $I = (i_1, \ldots, i_p)$ of positive integers with $a_1 + \cdots + a_m = n$; as with partitions we write $\ell(I)$ for the length of $I$. A morphism from $(i_1, \ldots, i_p) \in \mathcal{C}_n$ to
\((j_1, \ldots, j_q) \in \mathcal{C}_m\) is an order-preserving injective function \(f : [p] \to [q]\) such that \(i_a \leq j_{f(a)}\) for all \(a \in [p]\). Then \(\mathcal{C}\) is a unilateral updown category (but not simple). The weights \(u(I; J) = d(I; J)\) have an algebraic interpretation similar to that of the preceding two examples, but here one has to use the ring of quasi-symmetric functions (for definitions see [9 Sect. 9.4]): if \(M_I\) is the monomial quasi-symmetric function associated with \(I\), then
\[
M_I^k M_I = \sum_{|J| = |I| + k} u(I; J) M_J.
\]

The universal cover \(\tilde{\mathcal{C}}\) is constructed in [3] using Cayley permutations as defined in [8]: a Cayley permutation of level \(n\) is a length-\(n\) sequence \(s = (a_1, \ldots, a_n)\) of positive integers such that any positive integer \(i < j\) appears in \(s\) whenever \(j\) does. The covering map \(\pi : \tilde{\mathcal{C}} \to \mathcal{C}\) sends a sequence \(s\) to the composition \((m_1(s), m_2(s), \ldots)\). To relate this to the construction of Proposition 3.3, we again proceed inductively. Send the morphism from \(\hat{0}\) to \((1)\) to the Cayley permutation \((1)\), and suppose we have assigned to a chain \((h_1, h_2, \ldots, h_n)\) of morphisms between consecutive levels of \(\mathcal{C}\) from \(\hat{0}\) to \(I = (i_1, \ldots, i_k) \in \mathcal{C}_n\) a Cayley permutation \(s = (a_1, \ldots, a_n)\) that projects to \(I\): note that \(\max\{a_1, \ldots, a_n\} = k\). Now let \(h_{n+1} \in \text{Hom}(I, J)\) with \(J \in \mathcal{C}_{n+1}\). Then either \(\ell(J) = k\) and \(h_{n+1}\) is the identity function on \([k]\), or \(\ell(J) = k + 1\). In the first case, there is exactly one position \(q\) where \(J\) differs from \(I\): assign to \((h_1, \ldots, h_{n+1})\) the Cayley permutation \(s' = (a_1, \ldots, a_n, q)\). Then \(m_q(s') = m_q(s) + 1 = i_q + 1\) and \(m_i(s') = m_i(s)\) for \(i \neq q\), so \(s'\) projects to \(J\). In the second case, there is exactly one element \(q \in [k + 1]\) that \(h_{n+1}\) misses: assign \(s' = (h_{n+1}(a_1), \ldots, h_{n+1}(a_n), q)\) to \((h_1, \ldots, h_{n+1})\). Then \(\pi(s') = (m_1(s'), m_2(s'), \ldots)\) differs from \(I\) only in having an additional 1 inserted in the \(q^{th}\) place, and so must be \(J\).

The updown category \(\mathcal{C}\) satisfies the WCC with
\[
\epsilon(I) = \ell(I) + 2m_1(I) + 1,
\]
where \(m_1(I)\) is the number of 1’s in \(I\). This can be proved by induction on length using a method similar to that used for the preceding example. First, it is easy to show that
\[
(DU - UD)(I) = (2m_1(I) + 2)(I)
\]
when \(\ell(I) = 1\). Now let \(I \sqcup J\) be the juxtaposition of compositions \(I\) and \(J\), and extend \(\sqcup\) linearly to \(\kappa(\text{Ob} \mathcal{C})\). Then
\[
D(I \sqcup J) = D(I) \sqcup J + I \sqcup D(J)
\]
\[
U(I \sqcup J) = U(I) \sqcup J + I \sqcup D(U) - I \sqcup (1) \sqcup J
\]
for compositions \(I, J\). Hence we can calculate that
\[
(DU - UD)(I \sqcup J) = (DU - UD)(I) \sqcup J + I \sqcup (DU - UD)(J) - I \sqcup J.
\]
Since \(\ell\) and \(m_1\) are additive with respect to the operation \(\sqcup\), it follows that \(I \sqcup J\) is an eigenvector of \(DU - DU\) with eigenvalue given by equation (11) whenever \(I\) and \(J\) are.
Example 9. (Planar rooted trees; Example 4) Let \( P_n \) consist of functions \( f : [2n] \to \{-1, 1\} \) so that the partial sums \( S_i = f(1) + \cdots + f(i) \) have the properties that \( S_i \geq 0 \) for all \( 1 \leq i \leq 2n \), and \( S_{2n} = 0 \). We declare \( \text{Aut}(f) \) to be trivial for all objects \( f \) of \( P \), and define a morphism from \( f \in P_n \) to \( g \in P_{n+1} \) to be an injective, order-preserving function \( h : [2n] \to [2n + 2] \) such that the two values of \([2n + 2]\) not in the image of \( h \) are consecutive, and \( f(i) = gh(i) \) for \( 1 \leq i \leq 2n \). Then \( P \) is a unilateral updown category.

Using the well-known identification of balanced bracket arrangements with planar rooted trees, e.g. \((1,1,-1,1,1,-1,-1,-1)\) is identified with \( \text{\Diagram} \), we can think of \( P \) as the updown category of planar rooted trees; the level is the count of non-root vertices.

The weighted-relation poset \( Wrp(P) \) appears as Example 4 in [3], and its universal cover is described as the poset whose level-\( n \) elements are permutations \((a_1, a_2, \ldots, a_{2n})\) of the multiset \( \{1,1,2,2,\ldots,n,n\} \) such that, if \( a_i > a_j \) with \( i < j \), then there is some \( k < j, k \neq i \), such that \( a_k = a_i \). (The covering map sends a sequence \( s = (a_1, \ldots, a_{2n}) \) to a sequence of \( 1 \)'s and \(-1 \)'s by sending the first occurrence of \( i \) in \( s \) to \( 1 \) and the second to \(-1 \).) This construction can be identified with \( \tilde{P} \) as constructed in Proposition 3.3 in an obvious way. For example, consider the morphism from \( \tilde{0} = \emptyset \) to \((1,1,-1,1,-1,-1)\) given by the composition \( h_3 h_2 h_1 \), where \( h_1 = \emptyset \), \( h_2 = \{(1,1),(2,4)\} \) and \( h_3 = \{(1,1),(2,2),(3,3),(4,6)\} \). We can code the chain \((h_1, h_2, h_3)\) by the sequence \((1,2,2,3,3,1)\).

Using the tree language, we can think of \( U(t) \) as the sum of all planar rooted trees obtained by attaching a new edge and terminal vertex at every possible position of \( t \) (a sum with \( 2|t|+1 \) terms), and \( D(t) \) as the sum of all tree obtained by deleting a terminal edge of \( t \). For example,

\[
U(\text{\Diagram}) = \text{\Diagram} + \text{\Diagram} + \text{\Diagram} + \text{\Diagram} + \text{\Diagram}.
\]

and

\[
D(\text{\Diagram}) = \text{\Diagram} + \text{[terminal vertex]}.
\]

The updown poset \( P \) satisfies the WCC with

\[
\epsilon(t) = 2|t| + \tau(t) + 1,
\]

where \( \tau(t) \) is the number of terminal vertices of \( t \). This can be proved by a method similar to that of the preceding two examples, but here we need two operations: a binary operation \( \lor \) and a unary operation \( B_+ \). The binary operation \( \lor : P_n \times P_m \to P_{n+m} \) can be described as juxtaposition of balanced bracket arrangements, or equivalently as joining two planar rooted trees at the root:

\[
\text{\Diagram} \lor \text{[terminal vertex]} = \text{\Diagram}.
\]
The unary operation $B_+: \mathcal{P}_n \to \mathcal{P}_{n+1}$ encloses a balanced bracket operation in an outer pair of delimiters, or equivalently adds a new root vertex at the top of a planar rooted tree:

$$B_+( \begin{array}{c} \hline \end{array} ) = \begin{array}{c} \hline \end{array} .$$

Now it is straightforward to show that

$$D(t_1 \lor t_2) = D(t_1) \lor t_2 + t_1 \lor D(t_2)$$
$$U(t_1 \lor t_2) = U(t_1) \lor t_2 + t_1 \lor U(t_2) - t_1 \lor \begin{array}{c} \hline \end{array} \lor t_2$$

for any two planar rooted trees $t_1, t_2$, and that

$$D(B_+(t)) = B_+(D(t))$$
$$U(B_+(t)) = B_+(U(t)) + \begin{array}{c} \hline \end{array} \lor U(t) + U(t) \lor \begin{array}{c} \hline \end{array}$$

for any planar rooted tree $t$. Using the first pair of these equations, we can calculate that

$$(DU - UD)(t_1 \lor t_2) = (DU - UD)(t_1) \lor t_2 + t_1 \lor (DU - UD)(t_2) - t_1 \lor t_2$$

for any planar rooted trees $t_1, t_2$: since $\tau(t_1 \lor t_2) = \tau(t_1) + \tau(t_2)$, it follows that $t_1 \lor t_2$ is an eigenvector of $DU - UD$ satisfying equation (12) whenever $t_1$ and $t_2$ are. Similarly, the second pair of equations gives

$$(DU - UD)B_+(t) = B_+((DU - UD)(t)) + 2B_+(t)$$

for any planar rooted tree $t$. Since $\tau(B_+(t)) = \tau(t)$, it follows that $B_+(t)$ is an eigenvector of $DU - UD$ satisfying (12) when $t$ is. Now any planar rooted tree $t$ with $|t| > 0$ can be written as either $t_1 \lor t_2$ or $B_+(t_1)$, so we can prove the result by induction on $|t|$.

**Example 10.** (Rooted trees; [3, Example 7]) Let $\mathcal{T}_n$ consist of partially ordered sets $P$ such that (1) $P$ has $n + 1$ elements; (2) $P$ has a greatest element; and (3) for any $v \in P$, the set of elements of $P$ exceeding $v$ forms a chain. The Hasse diagram of such a poset $P$ is a tree with the greatest element (the root vertex) at the top. A morphism of $\mathcal{T}_m$ to $Q \in \mathcal{T}_n$ is an injective order-preserving function $f : P \to Q$ that sends the root of $P$ to the root of $Q$, and which preserves covering relations (i.e., if $v \lessdot w$ in the partial order on $P$, then $f(v) \lessdot f(w)$ in the partial order on $Q$). Then $\mathcal{T}$ is an updown category.

The updown category $\mathcal{T}$ was studied extensively in [3], though without using the categorical language. To see that the construction of the preceding paragraph gives the same multiplicities as in [3], consider a morphism from $P \in \mathcal{T}_m$ to $Q \in \mathcal{T}_{n+1}$. Any such morphism misses only some terminal vertex $v \in Q$, so we can think of it as identifying $P$ with $Q - \{v\}$. Elements of

$$\text{Hom}(P, Q)/\text{Aut}(Q)$$

amount to different choices for the parent of $v$ in $Q$, i.e., different choices for terminal vertices of $P$ to which a new edge and vertex can be attached to form $Q$; this is $n(P; Q)$ as defined in [3]. On the other hand, elements of

$$\text{Hom}(P, Q)/\text{Aut}(P)$$

amount to different choices of $v$, and thus to different choices for an edge of $Q$ that when cut leaves $P$: this is $m(P;Q)$ as defined in [4].

The operators $U$ and $D$ on $k(\text{Ob} \mathcal{T})$ appear in §2 of [4] as $\mathfrak{U}$ and $\mathfrak{P}$ respectively. As is proved there (Proposition 2.2), $\mathcal{T}$ satisfies the LCC with $\epsilon(t) = |t| + 1$ (Note that the grading in [4] differs by 1 from the one used here.)

In [3] the weighted-relation poset $Wrp(\mathcal{T}^\uparrow)$ is discussed, and it is shown that the universal cover $\tilde{\mathcal{T}}^\uparrow$ can be described as permutations of $[n]$. Finding a simple description of the objects of $\tilde{\mathcal{T}}^\uparrow$ appears to be a harder problem.
