Abstract
Cross-lingual transfer has been shown to produce good results for dependency parsing of resource-poor languages. Although this avoids the need for a target language treebank, most approaches have still used large parallel corpora. However, parallel data is scarce for low-resource languages, and we report a new method that does not need parallel data. Our method learns syntactic word embeddings that generalise over the syntactic contexts of a bilingual vocabulary, and incorporates these into a neural network parser. We show empirical improvements over a baseline delexicalised parser on both the CoNLL and Universal Dependency Treebank datasets. We analyse the importance of the source languages, and show that combining multiple source-languages leads to a substantial improvement.

1 Introduction
Dependency parsing is a crucial component of many natural language processing (NLP) systems for tasks such as relation extraction (Bunescu and Mooney, 2005), statistical machine translation (Xu et al., 2009), text classification (Özgür and Güngörr, 2010), and question answering (Cui et al., 2005). Supervised approaches to dependency parsing have been very successful for many resource-rich languages, where relatively large treebanks are available (McDonald et al., 2005a). However, for many languages, annotated treebanks are not available, and are very costly to create (Böhmová et al., 2001). This motivates the development of unsupervised approaches that can make use of unannotated, monolingual data. However, purely unsupervised approaches have relatively low accuracy (Klein and Manning, 2004; Gelling et al., 2012).

Most recent work on unsupervised dependency parsing for low-resource languages has used the idea of delexicalized parsing and cross-lingual transfer (Zeman et al., 2008; Sogaard, 2011; McDonald et al., 2011; Ma and Xia, 2014). In this setting, a delexicalized parser is trained on a resource-rich source language, and is then applied directly to a resource-poor target language. The only requirement here is that the source and target languages are POS tagged must use the same tagset. This assumption is pertinent for resource-poor languages since it is relatively quick to manually POS tag the data. Moreover, there are many reports of high accuracy POS tagging for resource-poor languages (Duong et al., 2014; Garrette et al., 2013; Duong et al., 2013b). The cross-lingual delexicalized approach has been shown to significantly outperform unsupervised approaches (McDonald et al., 2011; Ma and Xia, 2014).

Parallel data can be used to boost the performance of a cross-lingual parser (McDonald et al., 2011; Ma and Xia, 2014). However, parallel data may be hard to acquire for truly resource-poor languages. Accordingly, we propose a method to improve the performance of a cross-lingual delexicalized parser using only monolingual data.

Our approach is based on augmenting the delexicalized parser using syntactic word embeddings. Words from both source and target language are mapped to a shared low-dimensional space based on their syntactic context, without recourse to parallel data. While prior work has struggled to efficiently incorporate word embedding information into the parsing model (Bansal et al., 2014; Andreas and Klein, 2014; Chen et al., 2014), we present a method for doing so using a neural net-

1Note that most research in this area (as do we) evaluates on simulated low-resource languages, through selective use of data in high-resource languages. Consequently parallel data is plentiful, however this is often not the case in the real setting, e.g., for Tagalog, where only scant parallel data exists (e.g., dictionaries, Wikipedia and the Bible).
work parser. We train our parser using a two stage process: first learning cross-lingual syntactic word embeddings, then learning the other parameters of the parsing model using a source language treebank. When applied to the target language, we show consistent gains across all studied languages.

This work is a stepping stone towards the more ambitious goal of a universal parser that can efficiently parse many languages with little modification. This aspiration is supported by the recent release of the Universal Dependency Treebank (Nivre et al., 2015) which has consensus dependency relation types and POS annotation for many languages.

When multiple source languages are available, we can attempt to boost performance by choosing the best source language, or combining information from several source languages. To the best of our knowledge, no prior work has proposed a means for selecting the best source language given a target language. To address this, we introduce two metrics which outperform the baseline of always picking English as the source language. We also propose a method for combining all available source languages which leads to substantial improvement.

The rest of this paper is organized as follows: Section 2 reviews prior work on unsupervised cross-lingual dependency parsing. Section 3 presents the methods for improving the delexicalized parser using syntactic word embeddings. Section 4 describes experiments on the CoNLL dataset and Universal Dependency Treebank. Section 5 presents methods for selecting the best source language given a target language.

2 Unsupervised Cross-lingual Dependency Parsing

There are two main approaches for building dependency parsers for resource-poor languages without using target-language treebanks: delexicalized parsing and projection (Hwa et al., 2005; Ma and Xia, 2014; Täckström et al., 2013; McDonald et al., 2011).

The delexicalized approach was proposed by Zeman et al. (2008). They built a delexicalized parser from a treebank in a resource-rich source language. This parser can be trained using any standard supervised approach, but without including any lexical features, then applied directly to parse sentences from the resource-poor language. Delexicalized parsing relies on the fact that parts-of-speech are highly informative of dependency relations. For example, an English lexicalized discriminative arc-factored dependency parser achieved 84.1% accuracy, whereas a delexicalized version achieved 78.9% (McDonald et al., 2005b; Täckström et al., 2013). Zeman et al. (2008) build a parser for Swedish using Danish, two closely-related languages. Søgaard (2011) adapt this method for less similar languages by choosing sentences from the source language that are similar to the target language. Täckström et al. (2012) additionally use cross-lingual word clustering as a feature for their delexicalized parser. Also related is the work by Naseem et al. (2012) and Täckström et al. (2013) who incorporated linguistic features from the World Atlas of Language Structures (WALS; Dryer and Haspelmath (2013)) for joint modelling of multi-lingual syntax.

In contrast, projection approaches use parallel data to project source language dependency relations to the target language (Hwa et al., 2005). Given a source-language parse tree along with word alignments, they generate the target-language parse tree by projection. However, their approach relies on many heuristics which would be difficult to adapt to other languages. McDonald et al. (2011) exploit both delexicalized parsing and parallel data, using an English delexicalized parser as the seed parser for the target languages, and updating it according to word alignments. The model encourages the target-language parse tree to look similar to the source-language parse tree with respect to the head-modifier relation. Ma and Xia (2014) use parallel data to transfer source language parser constraints to the target side via word alignments. For the null alignment, they used a delexicalized parser instead of the source language lexicalized parser.

In summary, existing work generally starts with a delexicalized parser, and uses parallel data typological information to improve it. In contrast, we want to improve the delexicalized parser, but without using parallel data or any explicit linguistic resources.

3 Improving Delexicalized Parsing

We propose a novel method to improve the performance of a delexicalized cross-lingual parser without recourse to parallel data. Our method uses no additional resources and is designed to com-
plement other methods. The approach is based on syntactic word embeddings where a word is represented as a low-dimensional vector in syntactic space. The idea is simple: we want to relexicalize the delexicalized parser using word embeddings, where source and target language lexical items are represented in the same space.

Word embeddings typically capture both syntactic and semantic information. However, we hypothesize (and later show empirically) that for dependency parsing, word embeddings need to better reflect syntax. In the next subsection, we review some cross-lingual word embedding methods and propose our syntactic word embeddings. Section 4 empirically compares these word embeddings when incorporated into a dependency parser.

3.1 Cross-lingual word embeddings

We review methods that can represent words in both source and target languages in a low-dimensional space. There are many benefits of using a low-dimensional space. Instead of the traditional “one-hot” representation with the number of dimensions equal to vocabulary size, words are represented using much fewer dimensions. This confers the benefit of generalising over the vocabulary to alleviate issues of data sparsity, through learning representations encoding lexical relations such as synonymy.

Several approaches have sought to learn cross-lingual word embeddings from parallel data (Hermann and Blunsom, 2014a; Hermann and Blunsom, 2014b; Xiao and Guo, 2014; Zou et al., 2013; Täckström et al., 2012). Hermann and Blunsom (2014a) induced a cross-lingual word representation based on the idea that representations for parallel sentences should be close together. They constructed a sentence level representation as a bag-of-words summing over word-level representations, and then optimized a hinge loss function to match a latent representation of both sides of a parallel sentence pair. While this might seem well suited to our needs as a word representation in cross-lingual parsing, it may lead to overly semantic embeddings, which are important for translation, but less useful for parsing. For example, “economic” and “economical” will have a similar representation despite having different syntactic features.

Also related is (Täckström et al., 2012) who build cross-lingual word representations using a variant of the Brown clusterer (Brown et al., 1992) applied to parallel data. Bansal et al. (2014) and Turian et al. (2010) showed that for monolingual dependency parsing, the simple Brown clustering based algorithm outperformed many word embedding techniques. In this paper we compare our approach to forming cross-lingual word embeddings with those of both Hermann and Blunsom (2014a) and Täckström et al. (2012).

3.2 Syntactic Word Embedding

We now propose a novel approach for learning cross-lingual word embeddings that is more heavily skewed towards syntax. Word embedding methods typically exploit word co-occurrences, building on traditional techniques for distributional similarity, e.g., the co-occurrences of words in a context window about a central word. Bansal et al. (2014) suggested that for dependency parsing, word embeddings be trained over dependency relations, instead of adjacent tokens, such that embeddings capture head and modifier relations. They showed that this strategy performed much better than surface embeddings for monolingual dependency parsing. However, their method is not applicable to our low resource setting, as it requires a parse tree for training. Instead we consider a simpler representation, namely part-of-speech contexts. This requires only POS tagging, rather than full parsing, while providing syntactic information linking words to their POS context, which we expect to be informative for characterising dependency relations.
Algorithm 1 Syntactic word embedding

1: Match the source and target tagsets to the Universal Tagset.
2: Extract word n-gram sequences for both the source and target language.
3: For each n-gram, keep the middle word, and replace the other words by their POS.
4: Train a skip-gram word embedding model on the resulting list of word and POS sequences from both the source and target language.

We assume the same POS tagset is used for both the source and target language, and learn word embeddings for each word type into the same syntactic space of nearby POS contexts. In particular, we develop a predictive model of the tags to the left and right of a word, as illustrated in Figure 1 and outlined in Algorithm 1. Figure 1 illustrates two training contexts extracted from our English source and Spanish target language, where the highlighted fragments reflect the tags being predicted around each focus word. Note that for this example, the POS contexts for the English and Spanish verbs are identical, and therefore the model would learn similar word embeddings for these terms, and bias the parser to generate similar dependency structures for both terms.

There are several motivations for our approach: (1) POS tags are too coarse-grained for accurate parsing, but with access to local context they can be made more informative; (2) leaving out the middle tag avoids duplication because this is already known to the parser; (3) dependency edges are often local, as shown in Figure 1, i.e., there are dependency relations between most words and their immediate neighbours. Consequently, training our embeddings to predict adjacent tags is likely to learn similar information to training over dependency edges. Bansal et al. (2014) studied the effect of word embeddings on dependency parsing, and found that larger embedding windows captured more semantic information, while smaller windows better reflected syntax. Therefore we choose a small ±1 word window in our experiments. We also experimented with bigger windows (±2, ±3) but observed performance degradation in these cases, supporting the argument above.

Step 4 of Algorithm 1 finds the word embeddings as a side-effect of training a neural language model. We use the skip-gram model (Mikolov et al., 2013), trained to predict context tags for each word. The model is formulated as a simple bilinear logistic classifier

\[
P(t_c | w) = \frac{\exp(u^T_c v_w)}{\sum_{z=1}^{T} \exp(u^T_z v_w)}
\]

where \( t_c \) is the context tag around the current word \( w \), \( U \in \mathbb{R}^{T \times D} \) is the tag embedding matrix, \( V \in \mathbb{R}^{V \times D} \) is the word embedding matrix, with \( T \) the number of tags, \( V \) is the total number of word types over both languages and \( D \) the capacity of the embeddings. Given a training set of word and POS contexts, \( (t^1_c, w_1, t^1_l, l_1)_{i=1}^{N} \), we maximize the log-likelihood \( \sum_{i=1}^{N} \log P(t^1_c | w_1) + \log P(t^1_l | w_1) \) with respect to \( U \) and \( V \) using stochastic gradient descent. The learned \( V \) matrix of word embeddings is later used in parser training (the source word embeddings) and inference (the target word embeddings).

3.3 Parsing Algorithm

In this Section, we show how to incorporate the syntactic word embeddings into a parsing model. Our parsing model is built based on the work of Chen and Manning (2014). They built a transition-based dependency parser using a neural-network. The neural network classifier will decide which transition is applied for each configuration.
The architecture of the parser is illustrated in Figure 2, where each layer is fully connected to the layer above.

For each configuration, the selected list of words, POS tags and labels from the Stack, Queue and Arcs are extracted. Each word, POS or label is mapped to a low-dimension vector representation (embedding) through the Mapping Layer. This layer simply concatenates the embeddings which are then fed into a two-layer neural network classifier to predict the next parsing action. The set of parameters for the neural network classifier is $E_{\text{word}}, E_{\text{pos}}, E_{\text{labels}}$ for the mapping layer, $W_1$ for the hidden layer and $W_2$ for the soft-max output layer. We incorporate the syntactic word embeddings into the neural network model by setting $E_{\text{word}}$ to the syntactic word embeddings, which remain fixed during training so as to retain the cross-lingual mapping.\(^5\)

3.4 Model Summary

To apply the parser to a resource-poor target language, we start by building syntactic word embeddings between source and target languages as shown in algorithm 1. Next we incorporate syntactic word embeddings using the algorithm proposed in Section 3.3. The third step is to substitute source- with target-language syntactic word embeddings. Finally, we parse the target language using this substituted model. In this way, the model will recognize lexical items for the target language.

4 Experiments

We test our method of incorporating syntactic word embeddings into a neural network parser, for both the existing CoNLL dataset (Buchholz and Marsi, 2006; Nivre et al., 2007) and the newly-released Universal Dependency Treebank (Nivre et al., 2015). We employed the Unlabeled Attachment Score (UAS) without punctuation for comparison with prior work on the CoNLL dataset. Where possible we also report Labeled Attachment Score (LAS) without punctuation. We use English as the source language for this experiment.

4.1 Experiments on CoNLL Data

In this section we report experiments involving the CoNLL-X and CoNLL-07 datasets. Running on this dataset makes our model comparable with prior work. For languages included in both datasets, we use the newer one only. Crucially, for the delexicalized parser we map language-specific tags to the universal tagset (Petrov et al., 2012). The syntactic word embeddings are trained using POS information from the CoNLL data.

There are two baselines for our experiment. The first one is the unsupervised dependency parser of Klein and Manning (2004), the second one is the delexicalized parser of Täckström et al. (2012). We also compare our syntactic word embedding with the cross-lingual word embeddings of Hermann and Blunsom (2014a). These word embeddings are induced by running each language pair using Europarl (Koehn, 2005). We incorporated Hermann and Blunsom (2014a)’s cross-lingual word embeddings into the parsing model in the same way as for the syntactic word embeddings. Table 1 shows the UAS for 8 languages for several models. The first observation is that the direct transfer delexicalized parser outperformed the unsupervised approach. This is consistent with many prior studies. Our implementation of the direct transfer model performed on par with Täckström et al. (2012) on average. Table 1 also shows that using HB embeddings improve the performance over the Direct Transfer model. Our model using syntactic word embedding consistently out-performed the Direct Transfer model and HB embedding across all 8 languages. On average, it is 1.5% and 1.3% better.\(^6\)

The improvement varies across languages compared with HB embedding, and falls in the range of 0.3 to 2.6%. This confirms our initial hypothesis that we need word embeddings that capture syntactic instead of semantic information.

It is not strictly fair to compare our method with prior approaches to unsupervised dependency parsing, since they have different resource requirement, i.e. parallel data or typological resources. Compared with the baseline of the direct transfer model, our approach delivered a 1.5% mean performance gain, whereas Täckström et al. (2012) and McDonald et al. (2011) report approximately 3% gain, Ma and Xia (2014) and Naseem et al. (2012) report an approximately 6% gain. As we

\(^5\)This is a consequence of only training the parser on the source language. If we were to update embeddings during parser training this would mean they no longer align with the target language embeddings.

\(^6\)All performance comparisons in this paper are absolute.
Table 1: Comparative results on the CoNLL corpora showing UAS for several parsers: unsupervised induction Klein and Manning (2004), Direct Transfer (DT) delexicalized parser of Täckström et al. (2012), our implementation of Direct Transfer and our neural network parsing model using cross-lingual embeddings Hermann and Blunsom (2014a) (HB) and our proposed syntactic embeddings.

Table 2: Number of tokens ($\times 1000$) for each language in the Universal Dependency Treebank.

|     | cs  | de  | en  | es  | fi  | fr  | ga  | hu  | it  | sv  |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Train | 1173.3 | 269.6 | 204.6 | 382.4 | 162.7 | 354.7 | 16.7 | 20.8 | 194.1 | 66.6 |
| Dev  | 159.3 | 12.4 | 25.1 | 41.7 | 9.2  | 38.9 | 3.2  | 3.0  | 10.5 | 9.8  |
| Test | 173.9 | 16.6 | 25.1 | 8.5  | 9.1  | 7.1  | 3.8  | 2.7  | 10.2 | 20.4 |
| Total | 1506.5 | 298.6 | 254.8 | 432.6 | 181  | 400.7 | 23.7 | 26.5 | 214.8 | 96.8 |

Our direct transfer outperformed the unsupervised induction and the delexicalized parser of Täckström et al. (2012) in terms of average precision. Our model with cross-lingual embeddings achieved better performance than the direct transfer model, indicating the effectiveness of incorporating these embeddings into our model. The difference between UAS and LAS suggests that the model struggles with edge prediction, which is more complex in the Universal Dependency Treebank due to its richer annotation.

4.2 Experiments with Universal Dependency Treebank

We also experimented with the Universal Dependency Treebank V1.0, which has many desirable properties for our system, e.g. dependency types and coarse POS are the same across languages. This removes the need for mapping the source and target language tagsets to a common tagset, as was done for the CoNLL data. Secondly, instead of only reporting UAS we can report LAS, which is impossible on CoNLL dataset where the dependency edge labels differed among languages.

Table 2 shows the size in thousands of tokens for each language in the treebank. The first thing to observe is that some languages have abundant amount of data such as Czech (cs), French (fr) and Spanish (es). However, there are languages with modest size i.e. Hungarian (hu) and Irish (ga).

We ran our model with and without syntactic word embeddings for all languages with English as the source language. The results are shown in Table 3. The first observation is that our model using syntactic word embeddings outperformed direct transfer for all the languages on both UAS and LAS. We observed an average improvement of 3.6% (UAS) and 3.1% (LAS). This consistent improvement shows the robustness of our method of incorporating syntactic word embedding to the model. The second observation is that the gap between UAS and LAS is as big as 13% on average for both models. This reflects the increase difficulty of labelling the edges, with unlabelled edge prediction involving only a 3-way classification\(^7\) while labelled edge prediction involves an 81-way classification.\(^8\) Narrowing the gap between UAS and LAS for resource-poor languages is an important research area for future work.

5 Different Source Languages

In the previous sections, we used English as the source language. However, English might not be the best choice. For the delexicalized parser, it is crucial that the source and target languages have similar syntactic structures. Therefore a different choice of source language might substantially change the performance, as observed in prior studies (Täckström et al., 2013; Duong et al., 2013a; McDonald et al., 2011).

\(^7\)Since there are only 3 transitions: SHIFT, LEFT-ARC, RIGHT-ARC.

\(^8\)Since the Universal Dependency Treebank has 40 universal relations, each relation is attached to LEFT-ARC or RIGHT-ARC. The number 81 comes from 1 (SHIFT) + 40 (LEFT-ARC) + 40 (RIGHT-ARC).
In this section we assume that we have multiple source languages. To see how the performance changes when using a different source language, we run our best model (i.e., using syntactic embeddings) for each language pair in the Universal Dependency Treebank. Table 4 shows the UAS for each language pair, and the average across all target languages for each source language. We also considered LAS, but observed similar trends, and therefore only report the average LAS for each source language. Observe that English is rarely the best source language; Czech and French give a higher average UAS and LAS, respectively. Interestingly, while Czech gives high UAS on average, it performs relatively poorly in terms of LAS.

One might expect that the relative performance from using different source languages is affected by the source corpus size, which varies greatly. We tested this question by limiting the source corpora 66K sentences (and excluded the very small ga and hu datasets), which resulted in a slight reduction in scores but overall a near identical pattern of results to the use of the full sized source corpora reported in Table 4. Only in one instance did the best source language change (for target fi with source de not cs), and the average rankings by UAS and LAS remained unchanged.

The ten languages considered belong to five families: Romance (French, Spanish, Italian), Germanic (German, English, Swedish), Slavic (Czech), Uralic (Hungarian, Finnish), and Celtic (Irish). At first glance it seems that language pairs in the same family tend to perform well. For example, the best source language for both French and Italian is Spanish, while the best source language for Spanish is French. However, this doesn’t hold true for many target languages. For example, the best source language for both Finnish and German is Czech. It appears that the best choice of an appropriate source language is not predictable from language family information.

We therefore propose two methods to predict the best source language for a given target language. In devising these methods we assume that for a given resource-poor target language we do not have access to any parsed data, as this is expensive to construct. The first method is based on the Jensen-Shannon divergence between the distributions of POS n-grams ($1 < n < 6$) in a pair of languages. The second method converts each language into a vector of binary features based on word-order information from WALS, the World
Table 5: UAS for target languages where the source language is selected in different ways. English uses
English as the source language. WALS and POS choose the best source language using the WALS or
POS ngrams based methods, respectively. Oracle always uses the best source language. Combined is the
model that combines information from all available sources language. The UAS/LAS columns show the
UAS/LAS average performance across 9 languages (English is excluded).

|       | cs | de | en | es | fi | fr | ga | hu | it | sv | UAS | LAS |
|-------|----|----|----|----|----|----|----|----|----|----|-----|-----|
| English | 50.2 | 60.9 | —  | 67.9 | 51.4 | 66.0 | 51.6 | 52.3 | 69.2 | 59.6 | 58.8 | 45.8 |
| WALS   | 50.2 | 59.2 | 44.5 | 72.1 | 51.4 | 73.3 | 53.8 | 44.6 | 77.4 | 59.6 | 60.2 | 47.1 |
| POS    | 49.1 | 58.5 | 53.2 | 74.8 | 53.7 | 73.3 | 53.8 | 56.7 | 76.2 | 56.8 | 61.4 | 47.7 |
| Oracle | 60.5 | 65.9 | 63.2 | 74.8 | 53.7 | 73.3 | 59.0 | 56.7 | 77.4 | 59.6 | 64.5 | 50.8 |
| Combined | 61.1 | 67.5 | 64.4 | 75.1 | 54.2 | 72.8 | 58.7 | 57.9 | 76.7 | 60.5 | 64.9 | 52.0 |

Atlas of Language Structures (Dryer and Haspelmath, 2013). These features include the relative
order of adjective and noun, etc, and we compute
the cosine similarity between the vectors for a pair of languages.

As an alternative to selecting a single source
language, we further propose a method to combine
information from all available source languages to
build a parser for a target language. To do so we
first train the syntactic word embeddings on all the
languages. After this step, lexical items from all
source languages and the target language will be
in the same space. We train our parser with syn-
tactic word embeddings on the combined corpus
of all source languages. This parser is then applied
to the target language directly. The intuition here
is that training on multiple source languages limits
over-fitting to the source language, and learns the
“universal” structure of languages.

Table 5 shows the performance of each target
language with the source language given by the
model (in the case of models that select a single
source language). Always choosing English as the source language performs worst. Using
WALS features out-performs English on 7 out of
9 languages. Using POS ngrams out-performs the
WALS feature model on average for both UAS
and LAS, although the improvement is small. The
combined model, which combines information from all available source languages, out-performs
choosing a single source language. Moreover, this
model performs even better than the oracle model,
which always chooses the single best source lan-
guage, especially for LAS. Compared with the
baseline of always choosing English, our com-
bined model gives an improvement about 6% for
both UAS and LAS.

6 Conclusions

Most prior work on cross-lingual transfer depend-
cency parsing has relied on large parallel corpora.
However, parallel data is scarce for resource-poor
languages. In the first part of this paper we investi-
gated building a dependency parser for a resource-
poor language without parallel data. We improved
the performance of a delexicalized parser using
syntactic word embeddings using a neural net-
work parser. We showed that syntactic word em-
beddings are better at capturing syntactic infor-
mation, and particularly suitable for dependency
parsing. In contrast to the state-of-the-art for un-
supervised cross-lingual dependency parsing, our
method does not rely on parallel data. Although
the state-of-the-art achieves bigger gains over the
baseline than our method, our approach could be
more-widely applied to resource-poor languages
because of its lower resource requirements. More-
over, we have described how our method could be
used to complement previous approaches.

The second part of this paper studied ways of
improving performance when multiple source lan-
guages are available. We proposed two methods
to select a single source language that both lead
to improvements over always choosing English as
the source language. We then showed that we can
further improve performance by combining informa-
tion from all the source languages. In summary,
without any parallel data, we managed to improve
the direct transfer delexicalized parser by about
10% for both UAS and LAS on average, for 9 lan-
guages in the Universal Dependency Treebank.

In this paper we focused only on word em-
beddings, however, in future work we could also
build the POS embeddings and the arc-label em-
beddings across languages. This could help our
system to move more freely across languages, facilitating not only the development of NLP for resource-poor languages, but also cross-language comparisons.

Acknowledgments

This work was supported by the University of Melbourne and National ICT Australia (NICTA). Dr Cohn is the recipient of an Australian Research Council Future Fellowship (project number FT130101105).
