BACKGROUND

As of April 20, more than 780,000 individuals had confirmed COVID-19 in the USA.1 In addition to threatening health, this outbreak could have financial consequences for those affected. One analysis estimated that 5.7 million Americans at high risk for severe COVID-19 are uninsured.2 Healthcare costs could deter such individuals from seeking care, particularly among disadvantaged groups, while burdening household finances. We analyzed a nationally representative survey to identify individuals at elevated risk for severe COVID-19 and, among these, those at high risk of financial toxicity from care at the start of the epidemic.

METHODS

We analyzed the 2018 Behavioral Risk Factor Surveillance System (BRFSS), a survey of the noninstitutionalized population conducted by the Centers for Disease Control (CDC). We identified the “COVID-19-increased risk” population based on CDC guidance2, 3: individuals 65 and older, and non-elderly adults with COPD, asthma, heart disease, severe obesity (BMI ≥ 40), kidney disease, and diabetes.

We first identified demographic characteristics and relevant state-level policies associated with being in the COVID-19-increased risk group among adults < 65. We used multivariable logistic regressions adjusted for age and sex to examine the association between being at COVID-19-increased risk (vs not increased risk) and five characteristics/state-level policies: race, income, urban/rural county of residence, residence in a state that had implemented the Affordable Care Act’s Medicaid expansion as of January 2018,4 and residence in a state that had issued a “stay-at-home” order as of March 30, 20205 (as one indicator for outbreak risk).

We next examined the rate of “inadequate insurance” within the high-risk population of any age. Inadequate insurance was defined as being uninsured or underinsured, i.e., insured, but having skipped a doctor visit within the last year because of cost. We examined the relationship between the five characteristics/state-level policies listed above and inadequate insurance in separate age- and sex-adjusted regressions.

We used STATA/SE 16.1 for all analyses, with weights and appropriate methods to account for the BRFSS’ complex sampling procedures. Analysis of the BRFSS does not constitute human subjects research per the Cambridge Health Alliance IRB.

RESULTS

Table 1 displays data on the prevalence of risk factors for severe COVID-19 among those < 65 years. Blacks, American Indians/Alaska Natives, and those of “other” race were significantly more likely, and Asians less likely, to be in the COVID-increased risk population relative to whites. Persons with lower (vs. high) incomes were more likely to be increased risk, as were those living in rural counties, Medicaid non-expansion states, and states that had not issued a stay-at-home order.

Within the COVID-19-increased risk population of adults, 16.9% (or 18.2 million individuals) were un- or underinsured. Among this increased risk group, those with low incomes, residing in a rural area, and of non-white race had higher rates of inadequate insurance (Table 2). High-risk persons living in Medicaid non-expansion states had 52% higher odds of being inadequately insured relative to those in expansion states (95% CI 1.43, 1.61; p < 0.001), and high-risk individuals residing in states that had not issued stay-at-home orders had 23% higher odds of inadequate insurance relative to those in other states (95% CI 1.16–1.30).

DISCUSSION

At the start of the outbreak, 18 million adults at increased risk of severe COVID-19 were inadequately insured and hence at risk of delay in seeking care because of cost concerns and of financial toxicity if hospitalized. Traditionally disadvantaged groups—racial minorities, low-income persons, and rural residents—were more likely to be at risk of severe COVID-19 (consistent with the experience of previous viral respiratory epidemics) and of financial harm. Those living in states that failed to expand Medicaid or issue a stay-at-home order were also at greater risk of severe disease and inadequate coverage.

Gaps in insurance coverage, and states’ decisions to reject Medicaid expansion and defer prevention measures, may hence exacerbate the damage wrought by
the COVID-19 epidemic, as well as health disparities. Rising unemployment after the onset of the epidemic in the USA will likely translate into health coverage losses that could further widen these gaps; our estimates of uninsurance and underinsurance are likely underestimates. These findings provide support for steps taken to address inadequacies in coverage for the diagnosis and treatment of COVID-19 and for the consideration of additional policies that could expand coverage during the economic downturn.

1Increased risk defined as adults reporting a diagnosis of chronic obstructive pulmonary disease, history of heart attack, angina/coronary heart disease, cancer (excluding skin cancer), diabetes (excluding pre-diabetes and gestational diabetes), current asthma, and severe obesity (BMI ≥ 40). Although the CDC includes liver disease and residence in a nursing home as indicators of high risk, the BRFSS does not include questions that allow identification of persons with chronic liver disease and excludes institutionalized individuals
2Adjusted for age (18–24, 25–34, 35–44, or 45–54) and sex (male, female). N = 734 individuals with don’t know, not sure, or refused responses for sex, who were excluded from adjusted analyses
3Values imputed by BRFSS for those who do not report race/ethnicity
4N = 42,852 individuals with missing income among those age < 65, who were excluded from these analyses
5Based on National Center for Health Statistics 2013 Urban – Rural Classification Scheme; those in one of the four metropolitan counties are classified as “urban” and those in one of the two non-metropolitan counties are classified as “rural.” Excludes 4817 individuals from Guam and Puerto Rico
6Based on summary from the Kaiser Family Foundation; status as of January 2018. Excludes 4817 individuals from Guam and Puerto Rico among those age < 65
7Based on summary from the Kaiser Family Foundation; status as of March 30, 2020. Excludes 4817 individuals from Guam and Puerto Rico among those age < 65
