Abstract

This paper deals with the analysis of the dynamic behavior of nonlinear systems subject to probabilistic uncertainties in the physical parameters. The Polynomial Chaos Expansion PCE is proposed to resolve this problem. The main objective is to estimate the probability distribution of the non linear dynamic response for a given dispersion of mass parameters. The method proposed allows notable performances in terms of efficiency and accuracy. This result comes from a comparison between the PCE performance with those offered by the Perturbation Method (PM) and the referential method Monte Carlo Simulation (MCS). This approach allows reducing the computational cost.

Keywords: Non Linear Structure; Uncertain Parameters; Polynomial Chaos Expansion; Perturbation Method.

Introduction

In a robust design process, the determination of the variability of the nonlinear dynamic response of a complex structure is essential. Uncertainties come from the tolerances of manufacturing, the boundary conditions and the external excitations. These structures are largely used in the fields of aerospace, automotive, civil engineering ...The uncertainty of the physical parameters; nonlinearity and complexity of the structure require the development of a complete mathematical approach for predicting the dynamic behavior variability.

In addition, several methods have been developed in the literature to take account of uncertain parameters in the nonlinear dynamic response. The reference method is the Monte Carlo simulation [1]. This method allows a statistical evaluation based on a large number of deterministic analyses by considering different values of uncertain parameters. However, it requires the generation of big size samples then generates a prohibitory time computing. This approach is thus very costly. Also, perturbation methods are widely used to calculate the first moments (mean, standard deviation) of dynamic response whose uncertain variables vary slightly. These techniques are based on the Taylor series development of the response around its mean.

This allows the direct determination of the variability of the response according to the physical parameters (mechanical and geometrical) random. Indeed, perturbation methods based on a development in Taylor series of second order [2] and Neumann expansion method [3] are generally efficient. Another development in the first order [4] gives similar results to the previous developments with a reduced time computing. Furthermore, another form of development is a Polynomial Chaos Expansion (PCE) [5, 6]. The stochastic solution may be expanded in terms of the polynomial chaos basis whose elements are obtained from orthogonal polynomial [7]. The properties of this polynomial basis are used to generate a system of deterministic equations. The resolution of this system is used to determine the variability of the response.

Recently Sarsri et al., [10] used the Component Mode Synthesis method coupled with the perturbation method to calculate the stochastic modes of large FE models with uncertain parameters for the linear problems. In another work, Sarsri et al., [9] developed an approach coupling Component Mode Synthesis reduction method and developing uncertainty by a polynomial chaos
expansion to calculate the frequency transfer functions and response temporal for linear stochastic structures.

Sinou J. et al., [10] proposed for simple structures, requiring no reduction, a technique taking into account uncertainties in nonlinear models, by combining the method of Harmonic Balance Method (HBM) and developing uncertainty by a polynomial chaos expansion. This work is an extension to the nonlinear problems. The aim is to estimate the stochastic nonlinear dynamic response for a large structure with a minimum computational cost. To do this, we develop a methodological approach taking into account uncertainties in nonlinear models, by combining the Newmark method and developing uncertainty by a polynomial chaos expansion.

Modeling of a Nonlinear Dynamical System

The governing equation of motion of a general non-linear Multiple Degrees of Freedom (MDOF) mechanical system and subject to external force \( \{F_e\} \) may be written in the following form:

\[
[M]\{\ddot{u}\} + [C]\{\dot{u}\} + [K]\{u\} + \{F_e\} = \{F_i\} \quad \text{------ (1)}
\]

In this equation, \([M]\) is the mass matrix, \([C]\) is the damping matrix \([K]\) is the stiffness linear matrix, \([u]\) is the displacement vector containing the structural Degrees Of Freedom DOF, \([F_{nl}]\) is the stiffens linear matrix, \([u]\) is the displacement vector for the nonlinear dynamic systems with uncertain parameters. We present an extension of this method existence and validity, in particular the reduced field of variation order. The perturbation method must obey in the conditions of average value. These developments are truncated at the second order. The perturbation method is largely employed in the field of the stochastic finite elements. It is based on an approximation the random variables by their development in Taylor series around their average value. But, in the time domain, the stochastic differential system Equation (1) has to be solved.

Stochastic Perturbation Method

The perturbation method is largely employed in the field of the stochastic finite elements. It is based on an approximation the random variables by their development in Taylor series around their average value. These developments are truncated at the second order. The perturbation method must obey in the conditions of average value. But, in the time domain, the stochastic differential system Equation (1) has to be solved. The first two moments of time response (average and variance), terms of same order on gets the following differential systems:

\[
\{u\} = \{u\}_0 + \{u\}_1 + \{u\}_2 + \ldots \quad \text{Zero order equation} \quad \text{------ (2)}
\]

\[
\{u\} = \{u\}_0 + \{u\}_1 + \{u\}_2 + \ldots \quad \text{First order equation} \quad \text{------ (3)}
\]

\[
\{u\} = \{u\}_0 + \{u\}_1 + \{u\}_2 + \ldots \quad \text{Second order equation} \quad \text{------ (4)}
\]

Let us assume that the uncertainty in nonlinear models, by combining the Newmark method and developing uncertainty by a polynomial chaos expansion. The unknown vectors displacement, velocity and acceleration are also developed through Taylor series as follows:

\[
\{F_{nl}(\{u\})\} = \{F_{nl}(\{u\}_0)\} + \frac{\partial F_{nl}(\{u\})}{\partial u} (\{u\}_1) + \frac{\partial^2 F_{nl}(\{u\})}{\partial u^2} (\{u\}_0, \{u\}_1) + \ldots \quad \text{----- (5)}
\]

\[
\{F_{nl}(\{u\})\} = \{F_{nl}(\{u\}_0)\} + \frac{\partial F_{nl}(\{u\})}{\partial u} (\{u\}_1) + \frac{\partial^2 F_{nl}(\{u\})}{\partial u^2} (\{u\}_0, \{u\}_1) + \ldots \quad \text{----- (6)}
\]

\[
\{F_{nl}(\{u\})\} = \{F_{nl}(\{u\}_0)\} + \frac{\partial F_{nl}(\{u\})}{\partial u} (\{u\}_1) + \frac{\partial^2 F_{nl}(\{u\})}{\partial u^2} (\{u\}_0, \{u\}_1) + \ldots \quad \text{----- (7)}
\]

One defines the vector of the average parameters \( \bar{\theta} \) and the quantity \( d\bar{\theta} = \bar{\theta} - \bar{\theta} \). All the matrices and vector in Equation (1) are random, and are expanded through second order Taylor series as follows:

\[
[M] = [M] + [M] d\bar{\theta} + [M]^2 d\bar{\theta}^2 + \ldots
\]

\[
[C] = [C] \quad \text{------ (8)}
\]

\[
[K] = [K] + [K] d\bar{\theta} + [K]^2 d\bar{\theta}^2 + \ldots
\]

\[
[F] = [F] + [F] d\bar{\theta} + [F]^2 d\bar{\theta}^2 + \ldots
\]

where \([.]\), \([.]^2\) and \([.]^n\) are deterministic matrices corresponding to the zero, the first and the second order partial derivatives with respect to the random parameter \( \bar{\theta} \) and given by:

\[
[X] = [X] \quad \text{------ (9)}
\]

\[
[X] = \frac{\partial [X]}{\partial \bar{\theta}} \quad \text{------ (10)}
\]

\[
[X] = \frac{1}{2} \frac{\partial^2 [X]}{\partial \bar{\theta}^2} \quad \text{------ (11)}
\]

Indicial notations are used, with indices \( n, p \) running over the sequence 0, 1, ..., \( I \). As well as the repeated indices summation.
Polynomial Chaos Expansion Method

The polynomial chaos expansion presented in this section analysis the dynamic behavior of structures with uncertain parameters. the physical properties of structural described by the mass [M], damping [C] and stiffens [K] are random matrices

Using a particular formulation of the stochastic finite element method the matrices [M], [C] and [K] can be represented in the form:

\[ [K] = \sum_{j=0}^{N} [K_j] \xi_j \]
\[ [C] = \sum_{j=0}^{N} [C_j] \xi_j \]
\[ [M] = \sum_{n=0}^{N} [M_n] \xi_n \]  ------ (8)

The temporal response of non linear dynamic systems with the random properties is also a random process the vectors \( u(t), \dot{u}(t) \) and \( \ddot{u}(t) \) are expanded along polynomial chaos basis.

\[ \{u(t)\} = \sum_{n=0}^{N} \{u_n(t)\} \psi_n(\xi) \]
\[ \{u(t)\} = \sum_{n=0}^{N} \{u_n(t)\} \psi_n(\xi) \]  ------ (9)
\[ \{u(t)\} = \sum_{n=0}^{N} \{u_n(t)\} \psi_n(\xi) \]

Where \( \psi_n(\xi) \) are multidimensional Hermit orthogonal polynomials in the random variables \( \xi \) defined by:

\[ \psi_n(\xi_1, \ldots, \xi_p) = (-1)^n \exp \left( \frac{1}{2} \right) \frac{\partial^n}{\partial \xi_1 \ldots \partial \xi_n} \psi(\xi_1, \ldots, \xi_p) \]

\( u_n(t), \dot{u}_n(t) \) and \( \ddot{u}_n(t) \) denote a vector determinist coefficients.

Subsisting all this development into equation of motion:

\[ \sum_{i=0}^{M} \sum_{n=0}^{N} \{u_n(t)\} \{M_i\} \{\dot{\xi}_i \psi_n\} + \]
\[ \sum_{j=0}^{C} \sum_{n=0}^{N} \{u_n(t)\} \{C_j\} \{\xi \psi_n\} + \]
\[ \sum_{k=0}^{K} \sum_{n=0}^{N} \{u_n(t)\} \{K_j\} \{\dot{\xi}_i \psi_n\} + \]
\[ f_n(\sum_{n=0}^{N} \{u_n(t)\} \psi_n) = \sum_{m=0}^{F} \{f_m\} \{\dot{\xi}_m \psi_n\} \]  ------ (11)

We multiply the equation obtained by \( \psi_m \). If we used averaged (integration on the domain of random variables), and use the orthogonality properties of polynomials, we obtained the following equation:

\[ \sum_{i=0}^{M} \sum_{n=0}^{N} \{u_n(t)\} \{M_i\} \frac{\partial^n}{\partial \xi_i \psi_m} + \]
\[ \sum_{j=0}^{C} \sum_{n=0}^{N} \{u_n(t)\} \{C_j\} \frac{\partial^n}{\partial \xi_j \psi_m} + \]
\[ \sum_{k=0}^{K} \sum_{n=0}^{N} \{u_n(t)\} \{K_j\} \frac{\partial^n}{\partial \xi_k \psi_m} + \]
\[ f_n(\sum_{n=0}^{N} \{u_n(t)\} \psi_n) = \sum_{m=0}^{F} \{f_m\} \frac{\partial^n}{\partial \xi_m \psi_m} \]  ------ (12)

\( \{\dot{\xi}_i \psi_n\} \) is the inner product defined by the mathematical expectation operator.

Using matrix notations the resulting algebraic non linear system can be rewritten as:

\[ [MG][\ddot{U}] + [CG][\dot{U}] + [KG][U] + [FG]\{u\} = \{FG\} \]  ------ (13)

with \( \{\ddot{U}\} = \begin{bmatrix} \ddot{u}_0 \\ \ddot{u}_1 \\ \vdots \\ \ddot{u}_n \end{bmatrix}, \{\dot{U}\} = \begin{bmatrix} \dot{u}_0 \\ \dot{u}_1 \\ \vdots \\ \dot{u}_n \end{bmatrix}, \{U\} = \begin{bmatrix} u_0 \\ u_1 \\ \vdots \\ u_n \end{bmatrix} \)

\[ [MG]^a = \sum_{k=0}^{M} [M_i] \{\dot{\xi}_i \psi_m\} \]
\[ [CG]^a = \sum_{j=0}^{C} [C_j] \{\xi \psi_m\} \]
\[ [KG]^a = \sum_{k=0}^{K} [K_i] \{\dot{\xi}_i \psi_m\} \]
\[ [FG]^a = \sum_{n=0}^{N} [F_m] \{\dot{\xi}_m \psi_m\} \]

Note that due to the orthogonality of polynomials, most of expressions \( \{\dot{\xi}_i \psi_m\} \) are zero.

The mean and variance values of \( \{u(t)\} \) are given directly by:

\[ \text{mean}(\{u(t)\}) = \{u_n(t)\} \]
\[
\text{var}\left(\{u(t)\}\right) = \left[\sum_{i=1}^{N} (u_i(t))^2 \cdot \varphi_i^2\right] \text{ } (14)
\]

**Stochastic Temporal Response**

The temporal response from time 0 to time T of equations (5, 6, 7 and 13) is required. The time T is subdivided into n intervals \(\Delta t = T/n\) and the numerically solution is obtained at times \(t_r\) \(r\in \mathbb{N}\) and 0 \(\leq r \leq n\). Assuming that the solutions at times \(t\) are known and that the solution at time \(t + \Delta t\) is required next. According to the Newmark method, the following assumption is used at time \((t + \Delta t)\):

\[
\left\{u(t + \Delta t)\right\} = \left\{u(t + \Delta t)\right\}^* - \frac{\delta}{2\alpha} (u(t))^{*2} \text{ } (15)
\]

With \(x\) can take 0, \(n\), \(np\) values.

In which, the two parameters \(\alpha\) and \(\delta\), verify \(\delta \geq 1/2\) and \(\alpha \geq (\delta + 0.5)/4\) in order to get accurate and stable solution. The following notations are used:

\[
\begin{align*}
\alpha_0 &= \frac{\delta}{\alpha(\Delta t)^2} \\
\alpha_1 &= \frac{\delta}{\alpha(\Delta t)} \\
\alpha_2 &= \frac{1}{\alpha(\Delta t)} \\
\alpha_3 &= \frac{1}{2\alpha} - 1 \\
\alpha_4 &= \frac{\delta}{\alpha} - 1 \\
\alpha_5 &= \frac{(\Delta t)}{2} \left(\frac{\delta}{\alpha} - 1\right) \\
\alpha_6 &= (\Delta t)(1 - \delta) \\
\alpha_7 &= (\Delta t)\delta
\end{align*}
\]

Based on these notations the following equations are resulted:

**For Perturbation Method**

**Zero order equation**

\[
\left[K_{eq}^0\right] \left\{u(t + \Delta t)\right\} = \left\{F_{eq}^0\right\} \text{ } (16)
\]

with:

\[
\begin{align*}
[K_{eq}^0] &= (K^0 + [K_0])^0 + a_i[M] + a_i[C]^0 \\
[K_0] &= \frac{\partial^2 F_{eq}^0}{\partial u} |_{\{u\}^0}
\end{align*}
\]

\[
\begin{align*}
\{F_{eq}^0\} &= \{F_{eq}(t + \Delta t)^0\} \\
&= \{M\}^0 \{u(t)\}^0 + a_i [u(t)]^0 + a_i [u(t)]^0 \\
&+ \{C\}^0 \{a_i[u(t)]^0 + a_i[u(t)]^0\}
\end{align*}
\]

First order equation

\[
\left[K_{eq}^1\right] \left\{u(t + \Delta t)\right\}^1 = \left\{F_{eq}^1\right\} \text{ } (17)
\]

with:

\[
\begin{align*}
[K_{eq}^1] &= (K^1 + [K_0])^1 + a_i[M]^1 + a_i[C]^1 \\
[K_0] &= \frac{\partial^2 F_{eq}^1}{\partial u} |_{\{u\}^0}
\end{align*}
\]

\[
\begin{align*}
\{F_{eq}^1\} &= \{F_{eq}(t + \Delta t)^1\} \\
&= \{M\}^0 \{u(t)\}^0 + a_i [u(t)]^0 + a_i [u(t)]^0 \\
&+ \{C\}^0 \{a_i[u(t)]^0 + a_i[u(t)]^0\}
\end{align*}
\]

Second order equation

\[
\left[K_{eq}^2\right] \left\{u(t + \Delta t)\right\}^2 = \left\{F_{eq}^2\right\} \text{ } (18)
\]

with:

\[
\begin{align*}
[K_{eq}^2] &= (K^2 + [K_0])^2 + a_i[M]^2 + a_i[C]^2 \\
[K_0] &= \frac{\partial^2 F_{eq}^2}{\partial u} |_{\{u\}^0}
\end{align*}
\]

\[
\begin{align*}
\{F_{eq}^2\} &= \{F_{eq}(t + \Delta t)^2\} \\
&= \{M\}^0 \{u(t)\}^0 + a_i [u(t)]^0 + a_i [u(t)]^0 \\
&+ \{C\}^0 \{a_i[u(t)]^0 + a_i[u(t)]^0\}
\end{align*}
\]

The solution of the problem is obtained by successively solving of the following algebraic equations:

\[
\begin{align*}
\{u(t + \Delta t)^0\} &= \left\{(K_{eq}^0)\right\}^{-1} \{F_{eq}^0\} \\
\{u(t + \Delta t)^1\} &= \left\{(K_{eq}^1)\right\}^{-1} \{F_{eq}^1\} \\
\{u(t + \Delta t)^2\} &= \left\{(K_{eq}^2)\right\}^{-1} \{F_{eq}^2\}
\end{align*}
\]

The mean and the variance values of displacement \(u(t+\Delta t)\) are given by: 

Lamrhari M, D Sarsri, Azrar L, Rahmoune M, Sbai K (2016) Dynamic Analysis of Nonlinear Stochastic Systems by Polynomial Chaos Expansion (PCE). Int J Aeronautics Aerospace Res, 5(4):001, 1-8.
For Polynomial Chaos Expansion Problem

\[
\left[ KG_{eq} \right]\{U(t + \Delta t)\} = \left\{ \mathcal{F}_{eq} \right\} \quad \text{(21)}
\]

with:

\[
KG_{eq} = \left[ KG \right] + \left[ KG_{st} \right] + a_i[MG] + a_i[CG]
\]

\[
\mathcal{F}_{eq}(t) = \mathcal{F}_{eq}(t + \Delta t)
\]

For non-linear discrete systems with stochastic parameters, some benchmark tests are elaborated to demonstrate the efficiency of the methodological approach. The presented method can be applied to continuous or discrete systems. In this article, we restrict ourselves to show the applicability and effectiveness of these methods for the dynamic analysis of nonlinear discrete systems with N DOF. A nonlinear dynamic system consisting of 20 masses connected by 21 springs nonlinear shown in Figure 1.

The solution of the problem is obtained by:

\[
\{U(t + \Delta t)\} = \left[ KG_{eq} \right]^{-1} \left\{ \mathcal{F}_{eq} \right\} \quad \text{(22)}
\]

With

\[
[U(t + \Delta t)] = \begin{bmatrix}
    u_1(t + \Delta t) \\
    u_2(t + \Delta t) \\
    \vdots \\
    u_n(t + \Delta t)
\end{bmatrix}
\]

The mean and the variance values of displacement \(u(t + \Delta t)\) are given by:

\[
E\{u(t + \Delta t)\} = \{u_0(t + \Delta t)\}
\]

\[
\text{Var}\{u(t + \Delta t)\} = \left\{ \sum_{i=1}^{N} \left\{ u_i(t + \Delta t) \right\} \left\{ \omega_i \right\} \right\} \quad \text{(23)}
\]

**Numerical Example**

For non-linear discrete systems with stochastic parameters, some benchmark tests are elaborated to demonstrate the efficiency of the methodological approach. The presented method can be applied to continuous or discrete systems. In this article, we restrict ourselves to show the applicability and effectiveness of these methods for the dynamic analysis of nonlinear discrete systems with N DOF. A nonlinear dynamic system consisting of 20 masses connected by 21 springs nonlinear shown in Figure 1.

The following characteristics are considered:

Masse: \(m_1 = m_2 = \ldots = m_{20} = 2\text{kg}\)

Linear stiffness: \(k_1, k_2, \ldots, k_{39}, k_{40}, k_{41}, k_{42} = 50\text{N/m}\)

Non linear cubic stiffness: \(k_2 = k_4 \Rightarrow k_{42} = 10\text{N/m}^3\)

In this study, it has been chosen to investigate the effects of uncertainties by considering different mass uncertain parameters. The mass parameter is supposed to be a random variable and defined as follows: \(m = m_0(1 + \sigma \varepsilon)\) Where \(\varepsilon\) is a zero mean value Gaussian random variable, \(m_0 = m_{21-30} = 2\text{kg}\) is the mean value. \(\varepsilon_m = 2\%, \varepsilon_m = 5\%\) and \(\varepsilon_m = 7\%\) are the standard deviation of this parameter. Firstly, the mean and variance of the magnitude of displacement have been computed by Polynomial Chaos Expansion, the perturbation method. The obtained results are compared with those given by the direct Monte Carlo simulation 700 simulations. The obtained results are plotted in Figures 2, 3 and 4 which correspond respectively to temporal displacements of the mass \(m_3\) for \(\varepsilon_m = 2\%, \varepsilon_m = 5\%\) and \(\varepsilon_m = 9\%\). Very small discrepancies between the predictions given by Polynomials Chaos Expansion, perturbation method and Monte Carlo simulation are observed. Again, if more accuracy is needed, then the higher order polynomial chaos can be easily used. In order to highlight the performances of the proposed approach in term of computation cost, the CPU time between the Polynomial Chaos Expansion, perturbation method and Monte Carlo simulation is given in Table 1. A spectacular time reduction is observed when using the Polynomial Chaos Expansion.

**Conclusion**

The main of this work is to provide the variability of the transient solution of a complex structure by considering geometric nonlinearities. We have achieved this by implementing temporal integration for the perturbation method, the polynomial chaos expansion and the Monte Carlo simulation. The perturbation method gives accurate results for low dispersions against when the dispersion increases the polynomial chaos expansion gives good results. The numerical tests show the accuracy of the results and minimization of cost calculation compared to Monte Carlo simulation.
