A discrete version of the Darboux transform for isothermic surfaces

Udo Hertrich-Jeromin, Tim Hoffmann and Ulrich Pinkall

March 24, 2022

Abstract

We study Christoffel and Darboux transforms of discrete isothermic nets in 4-dimensional Euclidean space: definitions and basic properties are derived. Analogies with the smooth case are discussed and a definition for discrete Ribaucour congruences is given. Surfaces of constant mean curvature are special among all isothermic surfaces: they can be characterized by the fact that their parallel constant mean curvature surfaces are Christoffel and Darboux transforms at the same time. This characterization is used to define discrete nets of constant mean curvature. Basic properties of discrete nets of constant mean curvature are derived.

1 Introduction

Stimulated by the integrable system approach to isothermic surfaces (cf. [5] or [8]) — or, better: to Darboux pairs of isothermic surfaces — “discrete isothermic surfaces” or “nets” have been introduced by Alexander Bobenko and Ulrich Pinkall [2]. For the development of this theory it seems having been crucial not to use the standard calculus for Möbius geometry but

\*Partially supported by the Alexander von Humboldt Stiftung and by the Forschungsinstitut für Mathematik, ETH Zürich

\^Transformations seem to play an important role in the relation of surface theory and integrable system theory.
a quaternionic approach — which is well developed in case of Euclidean ambient space. In \cite{3} the Christoffel transform (or “dual”) \cite{7} for discrete isothermic nets in Euclidean space — the Christoffel transform of an isothermic surface is closely related to the Euclidean geometry of the ambient space — is developed. The Christoffel transform is an important tool in the theory of isothermic surfaces in Euclidean space: it can be used to characterize minimal surfaces (cf. \cite{7}, \cite{3}) and surfaces of constant mean curvature (cf. \cite{12}) between all isothermic surfaces — for discrete nets of constant mean curvature we will later use this characterization as a definition.

Recently, a quaternionic calculus for Möbius differential geometry \cite{10} was developed. This approach turned out to be very well adapted to the theory of (Darboux pairs of) isothermic surfaces \cite{11} — based on these results a quaternionic description for the Darboux transform of isothermic surfaces in Euclidean 4-space $\mathbb{R}^4 \cong \mathbb{H}$ was given \cite{12}: any Darboux transform of an isothermic surface in $\mathbb{R}^4$ can be obtained as the solution of a Riccati type partial differential equation. This equation can easily be discretized which provides us with a discrete version of the Darboux transform. Note that it seems to be more natural to work in 4-dimensional ambient space rather than in the codimension 1 setting\cite{11}; for example the structure of our Riccati type equation becomes more clear in 4-dimensional ambient space.

After a comprehensive discussion of the cross ratio in Euclidean 4-space we recall the definition of a discrete isothermic net and prove the basic facts on the Christoffel transform in 4-dimensional ambient space. Then, we give a definition of the Darboux transform of discrete isothermic nets by discretizing the Riccati type partial differential equation which defines the Darboux transforms of an isothermic surface in the smooth case. In the smooth setting a Darboux transform of an isothermic surface is obtained as the second envelope of a suitable 2-parameter family of 2-spheres. In the discrete setting there naturally appears a “2-parameter family” of 2-spheres, too — this suggests a definition of the “discrete envelopes” of a “discrete Ribaucour congruence” which we briefly discuss. Following the definitions we prove Bianchi’s permutability theorems \cite{1} for multiple Darboux transforms and for the Darboux and the Christoffel transform in the discrete case. In the

\footnote{Apart from the fact that calculations can be done much easier in 3- or 4-dimensional ambient space it seems to be clear that most considerations on the Darboux transform of discrete isothermic nets can be done in arbitrary dimensions — ironically, there might occur problems with the Christoffel transform.}
final section we discuss discrete nets of constant mean curvature: (smooth) cmc surfaces can be characterized by the fact that their parallel cmc surface is a Christoffel and a Darboux transform of the original surface at the same time. We use this as a definition and discuss Darboux transforms of constant mean curvature of discrete nets of constant mean curvature.

To illustrate the effect of the Darboux transformation on discrete isothermic nets we have included a couple of pictures. Comparing these pictures with those in [12] (which were calculated using the “smooth theory”) the reader will observe considerable similarities — indicating another time the close relation with the “smooth theory”. A discrete isothermic net in Euclidean 3-space allows $\infty^4$ Darboux transforms into discrete isothermic nets in 3-space. Figure 1 shows a Darboux transform of a discrete isothermic net on the Clifford torus which is closed in one direction. The reader will recognize a typical behaviour of Darboux transforms: along one curvature line “bubbles” are “added” to the original net while, in the other direction, the transform approaches the original net asymptotically. From this typical behaviour we might expect that Darboux transforms of (smooth or discrete) isothermic nets on a torus will never become doubly periodic.

Figure 4 shows a periodic constant mean curvature Darboux transform of a discrete isothermic net on the cylinder — the corresponding smooth Darboux transform is a Bäcklund transform of the cylinder, at the same time [12]. The (also periodic) isothermic net (of constant mean curvature) shown in figure 11 is obtained by applying a second Darboux transformation. In the last section of the present paper we will show that discrete isothermic nets of constant mean curvature $H \neq 0$ allow $\infty^3$ Darboux transforms of constant mean curvature $H$. A similar theorem holds for discrete minimal nets (cf. [12]) — a minimal Darboux transform of an isothermic net on the catenoid is shown in figure 4. Other (obviously non minimal) Darboux transforms of the same catenoid net with “bubbles added” along different directions are displayed in figures 4 and 5 — these surfaces might help to “see” the “typical behaviour” of the minimal Darboux transform in figure 4 ...

---

3Discrete minimal nets are defined in [3]. As the proof for the theorem on cmc Darboux transforms of cmc nets relies on the permutability theorem for multiple Darboux transforms, the proof for that on minimal Darboux transforms of minimal nets depends on the permutability theorem for Christoffel and Darboux transforms — when we characterize minimal isothermic nets by the fact that their Christoffel transforms are isothermic nets on a 2-sphere.
Since the cross ratio plays a key role in our investigations on discrete isothermic surfaces and the Darboux transform it seems useful to discuss properties of

2 The Cross Ratio

of four points in Euclidean 4-space. In [3] Alexander Bobenko and Ulrich Pinkall introduce the (complex) cross ratio

\[ DV(Q_1, Q_2, Q_3, Q_4) = \text{Re}Q(Q_1, Q_2, Q_3, Q_4) \pm i \cdot |\text{Im}Q(Q_1, Q_2, Q_3, Q_4)| \]

where \( Q(Q_1, Q_2, Q_3, Q_4) = (Q_1 - Q_2)(Q_2 - Q_3)^{-1}(Q_3 - Q_4)(Q_4 - Q_1)^{-1} \) for four points \( Q_1, Q_2, Q_3, Q_4 \in \mathbb{R}^3 \cong \text{Im}H \) in Euclidean 3-space. If \( S \subset \mathbb{R}^3 \) is a 2-sphere containing these four points this is exactly the cross ratio of the four points interpreted as complex numbers on \( S \) as the Riemann sphere

\[ 4 \text{Note that this cross ratio is slightly different from the classical cross ratio: the classical one may be obtained by interchanging } Q_2 \text{ and } Q_3 \text{ in the above formula. This reflects the fact that in discrete surface theory it is more useful to consider the cross ratio as an invariant of a surface patch rather than an invariant of two point pairs.} \]
the ambiguity of the sign of the imaginary part in the cross ratio corresponds to the possible orientations of the sphere. Note that the imaginary part of the cross ratio vanishes exactly when the four points are concircular. In this case the four points do not determine a unique 2-sphere but a whole pencil of 2-spheres.

This construction holds perfectly for four points $Q_i, i = 1 \ldots 4$, in 4-dimensional Euclidean space $\mathbb{R}^4 \cong \mathbb{H}$:

**Definition (Cross Ratio):** The complex number

$$
DV(Q_1, Q_2, Q_3, Q_4) := \text{Re}Q(Q_1, Q_2, Q_3, Q_4) + i \cdot |\text{Im}Q(Q_1, Q_2, Q_3, Q_4)|,
$$

$$
Q(Q_1, Q_2, Q_3, Q_4) := (Q_1 - Q_2)(Q_2 - Q_3)^{-1}(Q_3 - Q_4)(Q_4 - Q_1)^{-1}
$$

is called the cross ratio of four points $Q_1, Q_2, Q_3, Q_4 \in \mathbb{R}^4 \cong \mathbb{H}$ in Euclidean 4-space — or of the quadrilateral $(Q_1, Q_2, Q_3, Q_4) \subset \mathbb{R}^4$, respectively.

It is a straightforward calculation to express the cross ratio in terms of the distances of the four points:

$$
DV(Q_1, Q_2, Q_3, Q_4) = \frac{[l_{12}^2 l_{34}^2 + l_{14}^2 l_{23}^2 - l_{13}^2 l_{24}^2] + i \sqrt{-\det((l_{ij}^2)_{i,j=1,\ldots,4})}}{2l_{14}^2 l_{23}^2}
$$

where $l_{ij} := |Q_i - Q_j|$. Note that the vertices of a planar quadrilateral are concircular if and only if the product of the diagonal lengths equals the sum of the products of the lengths of opposite sides. Consequently, the cross ratio of concircular points can be calculated from the lengths of two pairs of opposite edges.

---

5 Or, they are colinear. — But since we are doing Möbius geometry we do not distinguish circles and straight lines.

6 Note that for four points in the complex plane $C \subset \mathbb{H}$ (which already carries an orientation) we may simply use $Q$ itself as the cross ratio.

7 At this point we would like to thank Matthias Zürcher for helpful discussions.

8 This is reflected by the fact that

$$
-\det((l_{ij}^2)_{i,j=1,\ldots,4}) = (a + b + c)(-a + b + c)(a - b + c)(a + b - c)
$$

where $a = l_{12}l_{34}$, $b = l_{13}l_{24}$ and $c = l_{14}l_{23}$. Note that all factors are non negative which can be interpreted as triangle inequalities for the triangle with lengths $a$, $b$ and $c$. With this interpretation, the determinant in the cross ratio is 16 times the squared area of this triangle (Heron’s formula).
If we consider \( \mathbf{R}^4 \cong H = \{(Q, 1) | Q \in H\} \) as (a subset of) the conformal 4-sphere \( H P^1 = \{ V \cdot H | V \in H^2 \} \) the squared norms in this equation are replaced by a biquadratic function \( |Q_i - Q_j|^2 = D((Q_i, 1), (Q_j, 1)) \), i.e. \( D(V\lambda, W) = D(V, W\lambda) = |\lambda|^2D(V, W) \) for \( V, W \in H^2 \) and \( \lambda \in H \). Thus the cross ratio of four points is independent of the choice of homogeneous coordinates of the points and consequently it is a conformal invariant \([10]\).

As another consequence of the above equation (2) we derive the following identities for the cross ratio — note that the determinant in (4) is invariant under permutations of the four points:

\[
D_V(Q_4, Q_1, Q_2, Q_3) = \frac{1}{D_V(Q_2, Q_3, Q_4, Q_1)},
D_V(Q_1, Q_3, Q_2, Q_4) = 1 - D_V(Q_1, Q_2, Q_3, Q_4).
\]

(3)

The complex conjugation in these equations arises since we defined the cross ratio to have always a non negative imaginary part. With the help of these two identities we easily obtain a second set of identities,

\[
D_V(Q_1, Q_2, Q_3, Q_4) = D_V(Q_3, Q_4, Q_1, Q_2) = D_V(Q_2, Q_1, Q_4, Q_3) = D_V(Q_4, Q_3, Q_2, Q_1).
\]

(4)

The complete set of the twenty four identities for the cross ratio can be derived using these two sets of identities — they are symbolized in figure 2.

As a preparation we first give a planar version of our hexahedron lemma — which will take a central role throughout this paper:

**Lemma:** Given a quadrilateral \((x_1, x_2, x_3, x_4)\) in the complex plane and a complex number \(\lambda \in C\) there is a unique quadrilateral \((z_1, z_2, z_3, z_4)\) to each initial point \(z_1 \in C\) such that the cross ratio\\(^9\\) satisfy

\[
Q(z_1, z_2, z_3, z_4) = Q(x_1, x_2, x_3, x_4) =: \mu
Q(z_1, z_2, x_2, x_1) = Q(z_3, z_4, x_4, x_3) = \mu\lambda
Q(z_2, z_3, x_3, x_2) = Q(z_4, z_1, x_1, x_4) = \lambda.
\]

(5)

\\(^9\)Here, we use \(Q\) as the cross ratio of four points in the complex plane (cf. footnote \[4\]).
Figure 2: Identities for the complex cross ratio
\( Q(z_3, z_4, x_4, x_3) = \mu \lambda \) successively for \( z_2, z_3 \) and \( z_4 \). This defines us a unique quadrilateral \( (z_1, z_2, z_3, z_4) \) in the complex plane. What is left to do is to verify the remaining two cross ratios — since the calculations become fairly long we preferred to let the computer algebra system “Mathematica” do the work:

```math
QDVSolve[a_,Q1_,Q2_,Q3_] := Block[{X},
X = (Q2-Q3) (Q1-Q2)^(-1) a;
(1+X)^(-1) (X Q1 + Q3)
];
```

(* cross ratio of the initial quadrilateral: *)
\( x_4 = \text{QDVSolve}[m, x_1, x_2, x_3] \);

(* we compute the second quadrilateral: *)
\( z_2 = \text{QDVSolve}[m, 1, x_2, x_1, z_1] \);
\( z_3 = \text{QDVSolve}[1, 1, x_3, x_2, z_2] \);
\( z_4 = \text{QDVSolve}[m, 1, x_4, x_3, z_3] \);

(* we verify the remaining two cross ratios: *)
\( \text{Factor}[z_1 - \text{QDVSolve}[1, x_1, x_4, z_4]] \)
\( \text{Factor}[z_4 - \text{QDVSolve}[m, z_1, z_2, z_3]] \)

This completes the proof of the above lemma — note, that we could have omitted the last calculation since the cross ratio of the constructed quadrilateral can also be derived directly from figure 3.

This lemma can not be directly generalized to quadrilaterals in space since a given (complex) cross ratio does no longer determine the fourth vertex of a quadrilateral in space. But, in our applications we will only be interested in real cross ratios — and in this case the cross ratio does determine the fourth vertex. Thus, if we start with an initial quadrilateral \( (X_1, X_2, X_3, X_4) \) with concircular vertices and one vertex \( Z_1 \) of the other vertex we can construct successively the other vertices \( Z_2, Z_3 \) and \( Z_4 \) on the circles given by the point triples \( \{X_1, X_2, Z_1\}, \{X_2, X_3, Z_2\} \) and \( \{X_3, X_4, Z_3\} \). Since these circles are always given by three points lying on the 2-sphere \( S \) containing the circle through the vertices of the first quadrilateral and the initial vertex \( Z_1 \) the whole construction takes place on this 2-sphere. Consequently, we can prescribe one (real) cross ratio as above:

The Hexahedron lemma: Given a quadrilateral \( (X_1, X_2, X_3, X_4) \) in Euclidean 4-space with concircular vertices and a real number \( \lambda \in \mathbb{R} \) there is a
unique quadrilateral \((Z_1, Z_2, Z_3, Z_4)\) to each initial point \(Z_1 \in H\) such that
\[
\begin{align*}
\text{DV}(Z_1, Z_2, Z_3, Z_4) &= \text{DV}(X_1, X_2, X_3, X_4) =: \mu \\
\text{DV}(Z_1, Z_2, X_2, X_1) &= \text{DV}(Z_3, Z_4, X_4, X_3) = \mu \lambda \\
\text{DV}(Z_2, Z_3, X_3, X_2) &= \text{DV}(Z_4, Z_1, X_1, X_4) = \lambda.
\end{align*}
\]
Moreover, the vertices of the hexahedron \((X_1, X_2, X_3, X_4; Z_1, Z_2, Z_3, Z_4)\) lie on a 2-sphere \(S \subset H\).

Now, we are prepared to start our investigations on

3 \hspace{1em} \textbf{Discrete isothermic nets}

Away from umbilics isothermic surfaces in Euclidean 3-space can be defined by the existence of conformal curvature line parameters; the results from [11] and [12] suggest that this is a good definition in case of 4-dimensional ambient space, too. In the codimension 2 case this definition requires the normal bundle of the surface to be flat — otherwise, it makes no sense to speak of “curvature line coordinates”.

9
Following [4] a surface is parametrized by curvature lines if and only if the parameter lines divide the surface in infinitesimal (planar) rectangles and the surface is isothermic if and only if it is divided into infinitesimal squares by its lines of curvature (cf. [6]). We may reformulate these criteria in a Möbius invariant flavour using the cross ratio:

**Lemma:** A (smooth) surface is parametrized by curvature lines if and only if the parameter lines divide the surface in infinitesimal patches with negative real cross ratios and the surface is isothermic if and only if its curvature lines divide the surface in infinitesimal harmonic patches, i.e. with cross ratios -1.

These criteria may motivate the following definition of discrete isothermic nets — note that we prefer the notion of a “net” since this term refers to a parametrized surface rather than to a surface in space as a purely geometric object: a “discrete isothermic net” is the analog of an isothermic surface given through conformal curvature line parameters.
Definition (Discrete Curvature line Net, Discrete Isothermic Net): A map $F : \Gamma \to \mathbb{H}$, $\Gamma \subset \mathbb{Z}^2$, is called a discrete curvature line net if the vertices of all elementary quadrilaterals are concircular and the quadrilaterals are embedded:

$$
\text{DV}(F_{m,n}, F_{m+1,n}, F_{m+1,n+1}, F_{m,n+1}) < 0; \quad (7)
$$

it is called an isothermic net if all elementary quadrilaterals are harmonic:

$$
\text{DV}(F_{m,n}, F_{m+1,n}, F_{m+1,n+1}, F_{m,n+1}) = -1. \quad (8)
$$

It is possible to define more general “isothermic nets” or “isothermic surfaces” as a discrete version of isothermic surfaces given in arbitrary curvature line coordinates (see [3]). Even though some formulas have to be modified in this approach (see for example the definition of the “dual surface” in [3]) all the facts on the Christoffel and Darboux transforms of isothermic nets we are going to develop seem to hold in the more general setting. However, for this presentation we prefer the simpler and more enlightening approach we just introduced.

As in the codimension 1 case, discrete isothermic nets have a Christoffel transform (dual). And, in some sense, they can be characterized by the existence of a Christoffel transform:

Theorem and Definition (Christoffel transform): If a discrete net $F : \Gamma \to \mathbb{H}$ is isothermic then

$$
1 = \lambda(F_{m+1,n} - F_{m,n})(F_{m+1,n+1}^c - F_{m,n+1}^c),
$$

$$
-1 = \lambda(F_{m,n+1} - F_{m,n})(F_{m,n+1}^c - F_{m,n}^c), \quad (9)
$$

$\lambda \in \mathbb{R} \setminus \{0\}$, defines another discrete isothermic net $F^c : \Gamma \to \mathbb{H}$, a Christoffel transform (or dual) of $F$. Note that a Christoffel transform $F^c$ of an isothermic net $F$ is determined up to a scaling and its position in space.

If, on the other hand, (9) defines a second discrete net — i.e. (9) is integrable — then both nets are isothermic, or parallelogram nets.
This theorem has an analog for smooth surfaces: given a parametrized surface \( F : U \subset \mathbb{R}^2 \to \mathbb{H} \) the integrability condition for the \( \mathbb{H} \)-valued 1-form \( F^{-1}_x dx - F^{-1}_y dy \) is equivalent to \( F_{xy}^{-1} = 0 \) and \( F \) conformal — i.e. \( F \) is a conformal curvature line parametrization of an isothermic surface — or \( F_{xy} = 0 \) and hence \( F(x, y) = F_1(x) + F_2(y) \) is a translation surface — which is the smooth analog of a parallelogram net.

During the proof of this theorem let us denote by
\[
\begin{align*}
a &= F_{mn} + F_{m+1,n} - F_{m,n} + F_{m+1,n+1} - F_{m+1,n} - F_{m,n+1} + F_{m,n+1} - F_{m,n+1} + F_{m,n} - F_{m,n+1}, \\
b &= F_{m+1,n+1} - F_{m+1,n}, \\
c &= F_{m,n+1} - F_{m+1,n+1}, \\
d &= F_{m,n} - F_{m,n+1},
\end{align*}
\]
the edges of an elementary quadrilateral of the net \( F \). Clearly, we have
\[ 0 = a + b + c + d \]
— the closing condition for the net \( F \). The closing condition (“integrability”) for the dual net \( F^c \) reads
\[
0 = \frac{1}{a} - \frac{1}{b} + \frac{1}{c} - \frac{1}{d} - \frac{b}{|b|^2} - \frac{c}{|c|^2} + \frac{d}{|d|^2}. \tag{11}
\]
As a first consequence this shows that a necessary condition for the net \( F^c \) to close up is that the elementary quadrilaterals of \( F \) be planar. If we assume the quadrilateral of \( F \) to be planar we can rewrite (11) as
\[
0 = a \left( \frac{1}{a} - \frac{1}{b} + \frac{1}{c} - \frac{1}{d} \right) c = -[1 + ab^{-1}cd^{-1}]d - [1 + ad^{-1}bc^{-1}]b = [1 + ab^{-1}cd^{-1}] \cdot [a + c] \tag{12}
\]
where we used \( bcd = dcb \) for the last equality: see (15).

If \( F \) is an isothermic net its elementary quadrilaterals are planar with cross ratio \( ab^{-1}cd^{-1} = -1 \). Consequently, the net \( F^c \) closes up. The only thing left is to show that elementary quadrilaterals of \( F^c \) have cross ratio -1. But,
\[
-1 = ab^{-1}cd^{-1} = d^{-1}cb^{-1}a = \left[ \frac{1}{a} b \frac{1}{c} d \right]^{-1}
\]
which shows that \( F^c \) is an isothermic net, too. This proves the first part of our theorem.

To attack the second part we note that from the above calculation (12) it follows that two cases can occur if (9) is integrable: the quadrilateral under investigation has cross ratio \(-1 = ab^{-1}cd^{-1}\) or it is a parallelogram. Assuming that the quadrilaterals of \( F \) do not change their type we conclude that
F and (from the first part) \( F^c \) are isothermic nets or both nets are parallelogram nets. This completes the proof of the above theorem — provided we happen to prove the following

**Lemma:** Two vectors \( a, b \in \mathbb{R}^4 \cong H \) are linearly dependent if and only if

\[
\bar{a}b = b\bar{a}; \tag{14}
\]

three vectors \( a, b, c \in H \) are linearly dependent if and only if

\[
\bar{a}bc = c\bar{b}a; \tag{15}
\]

four vectors \( a, b, c, d \in H \) are linearly dependent if and only if

\[
\bar{a}bcd - \bar{d}c\bar{b}a = dcb\bar{a} - \bar{a}bcd. \tag{16}
\]

The first statement is immediately clear since this simply means that \( a \bar{b} \in \mathbb{R} \). To prove the second statement we calculate

\[
\bar{a}bc - c\bar{b}a = 2[\det(a_1, b_1, c_1), -(a_0 \cdot b_1 \times c_1 + b_0 \cdot c_1 \times a_1 + c_0 \cdot a_1 \times b_1)]
\]

where \( x_0 = \text{Re}x \) and \( x_1 = \text{Im}x \). A careful analysis of this equation provides the second statement. And third we have

\[
\text{Re}[\bar{a}bcd - \bar{d}c\bar{b}a] = 2 \det(a, b, c, d)
\]

which completes the proof\(^{10}\).

To motivate our ansatz for the Darboux transform of discrete isothermic nets let us shortly recall some facts on

### 4 The Darboux transform

of smooth isothermic surfaces. A sphere congruence (a 2-parameter family of spheres) \( S : M^2 \rightarrow \{\text{spheres and planes in } \mathbb{R}^3\} \) is said to be “enveloped” by a surface \( F : M^2 \rightarrow \mathbb{R}^3 \) if at each point the surface has first order contact

\(^{10}\)At this point we would like to thank Ekkehard Tjaden for helpful discussions.
to the corresponding sphere\footnote{For simplicity reasons we do not give exact definitions — we just want to give the ideas of the used terms. For a comprehensive discussion the reader is referred to the classical book of W. Blaschke\footnote{If the sphere congruence is, in a certain sense, “full”, i.e. if it is not a congruence of planes in some space of constant curvature.}}: $F(p) \in S(p)$ and $d_p F(T_p M) = T_{F(p)} S$. If a sphere congruence $S$ has two envelopes $F$ and $\hat{F}$ — which is, generically, the case — then it establishes a point to point correspondence between its two envelopes. From the works of Darboux\footnote{In\cite{12} we derived a Riccati type partial differential equation} and Blaschke\footnote{If the sphere congruence is, in a certain sense, “full”, i.e. if it is not a congruence of planes in some space of constant curvature.} we know that if this correspondence preserves curvature lines — the sphere congruence is a “Ribaucour sphere congruence” — and it is conformal, too, then generically\footnote{If the sphere congruence is, in a certain sense, “full”, i.e. if it is not a congruence of planes in some space of constant curvature.} both envelopes are isothermic surfaces. In this case the two envelopes are said to form a “Darboux pair”, one surface is said to be a “Darboux transform” of the other. These definitions can be generalized to codimension 2 surfaces in 4-dimensional space by introducing congruences of 2-spheres — which are not hyperspheres any more\footnote{For simplicity reasons we do not give exact definitions — we just want to give the ideas of the used terms. For a comprehensive discussion the reader is referred to the classical book of W. Blaschke\footnote{If the sphere congruence is, in a certain sense, “full”, i.e. if it is not a congruence of planes in some space of constant curvature.}}.

In\cite{12} we derived a Riccati type partial differential equation

$$d\hat{F} = (\hat{F} - F) dF^c(\hat{F} - F)$$

for Darboux transforms $\hat{F}$ of an isothermic surface $F$ where $F^c$ is a Christoffel transform of $F$. Note that in order to obtain every Darboux transform $\hat{F}$ of $F$ as a solution of (18), it is crucial not to fix the scaling of the Christoffel transform: rescalings of $F^c$ make $\hat{F}$ run through the associated family of Darboux transforms. Considering this Riccati equation as an initial value problem we see that an isothermic surface allows $\infty^5$ Darboux transforms — or, if we are interested in surfaces in 3-dimensional space, it allows $\infty^4$ Darboux transforms.

This Riccati type equation (17) can now be easily discretized to obtain a system of difference equations

$$\lambda(\hat{F}_{m+1,n} - \hat{F}_{m,n}) = (\hat{F}_{m,n} - F_{m,n})(F_{m+1,n} - F_{m,n})^{-1}(\hat{F}_{m+1,n} - F_{m+1,n})$$

$$\lambda(F_{m+1,n} - F_{m,n}) = -(\hat{F}_{m,n} - F_{m,n})(F_{m,n+1} - F_{m,n})^{-1}(\hat{F}_{m,n+1} - F_{m,n+1})$$

where we replaced the Christoffel transform $F^c$ of $F$ according to (\ref{eq:christoffel}). However, this ansatz is not unique: we also could have interchanged the roles of the edges connecting $F$ and $\hat{F}$ by replacing the previous equations by

$$\lambda(\hat{F}_{m+1,n} - \hat{F}_{m,n}) = (\hat{F}_{m+1,n} - F_{m+1,n})(F_{m+1,n} - F_{m,n})^{-1}(\hat{F}_{m,n} - F_{m,n})$$

$$\lambda(F_{m+1,n} - F_{m,n}) = -(\hat{F}_{m,n+1} - F_{m,n+1})(F_{m,n+1} - F_{m,n})^{-1}(\hat{F}_{m,n} - F_{m,n})$$

\footnotetext{For simplicity reasons we do not give exact definitions — we just want to give the ideas of the used terms. For a comprehensive discussion the reader is referred to the classical book of W. Blaschke.}

\footnotetext{If the sphere congruence is, in a certain sense, “full”, i.e. if it is not a congruence of planes in some space of constant curvature.}
— or we even could have used a mean value of the two. But, rewriting
these equations with the cross ratio we see from (4) that both ansatzes are
equivalent. Thus, without loss of generality we may use our first ansatz to
obtain the following

**Theorem and Definition (Darboux Transform):** If $F : \Gamma \to \mathcal{H}$ is an
isothermic net then the Riccati type system

$$\lambda = \text{DV}(F_{m,n}, \hat{F}_{m,n}, \hat{F}_{m+1,n}, F_{m+1,n})$$

$$-\lambda = \text{DV}(F_{m,n}, \hat{F}_{m,n}, \hat{F}_{m,n+1}, F_{m,n+1})$$

(18)

defines an isothermic net $\hat{F} : \Gamma \to \mathcal{H}$. Any solution $\hat{F}$ of (18) is called a
Darboux transform of $F$.

This theorem is an easy consequence of the hexahedron lemma (page 9). Note that
from the identities (4) for the cross ratio we see that the equations (18) are symmetric in $F$ and $\hat{F}$ — consequently, we also may refer to the
pair $(F, \hat{F})$ of isothermic nets as a Darboux pair.
As a second consequence from the hexahedron lemma we conclude that for a Darboux pair \((F, \hat{F})\) the vertices of the hexahedron
\[
(F_{m,n}, F_{m+1,n}, F_{m+1,n+1}, F_{m,n+1}; \hat{F}_{m,n}, \hat{F}_{m+1,n}, \hat{F}_{m+1,n+1}, \hat{F}_{m,n+1})
\]
lie on a sphere \(S_{(m,n)}\) — these spheres do naturally live on the “dual lattice”
\[
\Gamma^* := \{( (m,n), (m+1,n), (m+1,n+1), (m,n+1)) | (m,n), (m+1,n), (m+1,n+1), (m,n+1) \in \Gamma \}
\]  
(19)
of \(\Gamma\) which consists of the elementary quadrilaterals. Obviously, an (interior) point pair \((F_{m,n}, \hat{F}_{m,n})\) can be obtained as the intersection of four spheres \(S_{(m,n)}^*, S_{(m-1,n)}^*, S_{(m-1,n-1)}^* \) and \(S_{(m,n-1)}^*\). These facts suggest that the Darboux pair \((F, \hat{F})\) “envelopes” a discrete Ribaucour congruence:

**Definition (Envelopes of a Discrete Ribaucour Congruence):** Two discrete curvature line nets \(F, \hat{F} : \Gamma \to R^4\) are said to **envelope a discrete Ribaucour congruence** \(S : \Gamma^* \to \{2\text{-spheres and 2\text{-planes in } R^4}\}\) if (interior) point pairs \((F_{m,n}, \hat{F}_{m,n})\) lie on four consecutive spheres \(S_{(m,n)}^*, S_{(m-1,n)}^*, S_{(m-1,n-1)}^* \) and \(S_{(m,n-1)}^*\).

Note that we require the two envelopes to be curvature line nets — and consequently the sphere congruence to be Ribaucour. If we would omit this assumption the patches of one envelope could determine the spheres of the enveloped congruence uniquely since the four vertices of an elementary quadrilateral would not be concircular in general. But this would contradict the fact that in the smooth case there is always a pointwise 1-parameter freedom for an enveloped sphere congruence when one envelope is given.

The previous discussions indicate a strong similarity to the smooth case — to complete this picture we prove two fundamental “permutability theorems” which hold in the smooth case:

**Theorem:** If \(\hat{F}_1, \hat{F}_2 : \Gamma \to H\) are two Darboux transforms of an isothermic net \(F : \Gamma \to H\) with parameters \(\lambda_1\) and \(\lambda_2\), respectively, then there exists an isothermic net \(\hat{F} = \hat{F}_{12} = \hat{F}_{21} : \Gamma \to H\) which is a \(\lambda_2\)-Darboux transform of \(\hat{F}_1\) and a \(\lambda_1\)-Darboux transform of \(\hat{F}_2\) at the same time. The nets \(F, \hat{F}_1, \hat{F}_2\) and \(\hat{F}\) have constant cross ratio
\[
\frac{\lambda_2}{\lambda_1} = DV(F, \hat{F}_2, \hat{F}, \hat{F}_1).
\]  
(20)
This theorem is a discrete analog of Bianchi’s permutability theorem \[1\]. Again, it can be obtained as a consequence of the hexahedron lemma: let us pick one edge of an elementary quadrilateral of \( F \) and the corresponding edges of \( \hat{F}_1 \) and \( \hat{F}_2 \), as indicated in figure 6. We denote the vertices of these edges by \( X, Y, \hat{X}_1, \hat{Y}_1 \) and \( \hat{X}_2, \hat{Y}_2 \). Since \( \hat{F}_1 \) and \( \hat{F}_2 \) are Darboux transforms of \( F \) we have
\[
\text{DV}(X, \hat{X}_1, \hat{Y}_1, Y) = \pm \lambda_1, \\
\text{DV}(X, \hat{X}_2, \hat{Y}_2, Y) = \pm \lambda_2.
\]
Then, we can find two points \( \hat{X}, \hat{Y} \) such that
\[
\text{DV}(X, \hat{X}_2, \hat{X}, \hat{X}_1) = \text{DV}(Y, \hat{Y}_2, \hat{Y}, \hat{Y}_1) = \frac{\lambda_2}{\lambda_1}
\]
and, by the hexahedron lemma,
\[
\text{DV}(\hat{X}_1, \hat{X}, \hat{Y}, \hat{Y}_1) = \pm \lambda_2, \\
\text{DV}(\hat{X}_2, \hat{X}, \hat{Y}, \hat{Y}_2) = \pm \lambda_1.
\]
Repeating this construction for all four edges — note that by construction the resulting edges close up to form a quadrilateral — we obtain an elementary quadrilateral of an isothermic net \( \hat{F} \) which is a \( \lambda_1 \)-Darboux transform of \( \hat{F}_2 \) and a \( \lambda_2 \)-Darboux transform of \( \hat{F}_1 \), as desired. This completes the proof of our first permutability theorem.

Figure 6: Bianchi’s permutability theorem
Since the four surfaces in the permutability theorem have constant cross ratio (20) it becomes clear that there is an even fancier version of the permutability theorem which involves not just four but eight surfaces (cf. [1]): if we start with three Darboux transforms $\hat{F}_1, \hat{F}_2$ and $\hat{F}_3$ of an isothermic net $F$ we can construct three isothermic nets $\hat{F}_{12}, \hat{F}_{23}$ and $\hat{F}_{31}$ via
\[
\lambda_1 \lambda_2 \equiv \text{DV}(F, \hat{F}_2, \hat{F}_{12}, \hat{F}_1),
\lambda_2 \lambda_3 \equiv \text{DV}(F, \hat{F}_3, \hat{F}_{23}, \hat{F}_2),
\lambda_3 \lambda_1 \equiv \text{DV}(F, \hat{F}_1, \hat{F}_{31}, \hat{F}_3).
\]

(21)

Now, we may apply the construction a second time to obtain an eighth net $\hat{F}$ which satisfies
\[
\lambda_1 \lambda_3 \equiv \text{DV}(\hat{F}_3, \hat{F}_{31}, \hat{F}, \hat{F}_{23}),
\lambda_2 \lambda_3 \equiv \text{DV}(\hat{F}_1, \hat{F}_{12}, \hat{F}, \hat{F}_{31}),
\lambda_1 \lambda_3 \equiv \text{DV}(\hat{F}_2, \hat{F}_{23}, \hat{F}, \hat{F}_{12}).
\]

(22)

It is a consequence of the hexahedron lemma that the net $\hat{F}$ exists. This seems to be worth formulating a

**Corollary:** If $\hat{F}_i : \Gamma \to \mathbb{H}$, $i = 1, 2, 3$, are Darboux transforms of an isothermic net $F : \Gamma \to \mathbb{H}$ with parameters $\lambda_i$, then there exist four isothermic nets $F_{ij}, \hat{F} : \Gamma \to \mathbb{H}$, $ij = 12, 23, 31$, such that each $F_{ij}$ is a $\lambda_i$-Darboux transform of $\hat{F}_j$ and a $\lambda_j$-Darboux transform of $\hat{F}_i$ and such that $\hat{F}$ is a $\lambda_1$-Darboux transform of $\hat{F}_{23}$, a $\lambda_2$-Darboux transform of $\hat{F}_{31}$ and a $\lambda_3$-Darboux transform of $\hat{F}_{12}$, at the same time.

The second “permutability theorem” is a discrete version of the compatibility theorem for the Darboux and Christoffel transform of an isothermic surface [12] (cf. [1]):

**Theorem:** If $F, \hat{F} : \Gamma \to \mathbb{H}$ form a Darboux pair, then their Christoffel transforms $F^c, \hat{F}^c = \hat{F}^c : \Gamma \to \mathbb{H}$ form — if correctly scaled and positioned — a Darboux pair, too.

To prove this theorem we imitate the proof we gave in the smooth case [12]: first, let us consider the difference functions $G := \hat{F} - F : \Gamma \to \mathbb{H}$ and
\( G^c := \hat{F}^c - F^c : \Gamma \rightarrow H \). Since \( \hat{F} \) is a Darboux transform of \( F \) we have

\[
\lambda(\hat{F}_{m+1,n} - \hat{F}_{m,n}) = (\hat{F}_{m,n} - F_{m,n})(F_{m+1,n} - F_{m,n})^{-1}(\hat{F}_{m+1,n} - F_{m+1,n}),
\]
\[
\lambda(F_{m+1,n} - F_{m,n}) = (\hat{F}_{m,n} - F_{m,n})(\hat{F}_{m+1,n} - \hat{F}_{m,n})^{-1}(\hat{F}_{m+1,n} - F_{m+1,n}).
\]

Subtracting the first equation from the second one yields

\[
\lambda \left( \frac{1}{\hat{F}_{m+1,n} - \hat{F}_{m+1,n}} - \frac{1}{\hat{F}_{m,n} - F_{m,n}} \right) = \left( \frac{1}{\hat{F}_{m+1,n} - \hat{F}_{m,n}} - \frac{1}{F_{m+1,n} - F_{m,n}} \right)
\]

and consequently

\[
G_{m+1,n}^c - G_{m,n}^c = \frac{1}{G_{m+1,n}} - \frac{1}{G_{m,n}}
\]

if \( F^c \) and \( \hat{F}^c \) are scaled as in (9). In a similar way we obtain the same difference equation for the other direction

\[
G_{m,n}^c - G_{m,n+1}^c = \frac{1}{G_{m,n+1}} - \frac{1}{G_{m,n}}.
\]

Thus, we can position \( F^c \) and \( \hat{F}^c \) in \( \mathbb{R}^4 \) such that \( G_{m,n}^c = G_{m,n}^{-1} \). As in (13), we can now calculate the cross ratios

\[
\text{DV}(F^c_m,n, \hat{F}^c_m,n, \hat{F}^c_{m+1,n}, F^c_{m+1,n}) = \frac{\lambda^2}{\lambda} = \lambda,
\]
\[
\text{DV}(F^c_m,n, \hat{F}^c_m,n, F^c_{m+1,n}, \hat{F}^c_{m+1,n}) = -\lambda
\]

showing that \( F^c \) and \( \hat{F}^c \) form indeed a Darboux pair. This completes the proof.

Throughout the rest of the paper we will consider

5 Discrete nets of constant mean curvature

As is well known, (smooth) surfaces of constant mean curvature (cmc) in 3-dimensional Euclidean space are isothermic surfaces, i.e. — away from umbilics — they allow conformal curvature line parametrizations. In fact, we know that surfaces of constant mean curvature \((H \neq 0)\) are very special examples of isothermic surfaces in the context of Darboux and Christoffel
transforms: the (correctly scaled and positioned) Christoffel transform of a cmc surface $F : U \subset \mathbb{R}^2 \to \mathbb{R}^3$ with unit normal field $N : U \to S^2$ is its parallel constant mean curvature surface $F^p = F + \frac{1}{2\pi}N$. On the other hand, this parallel cmc surface is also a Darboux transform since a congruence of spheres with constant radius $\frac{1}{2\pi}$ is certainly a Ribaucour sphere congruence and — as is well known — a cmc surface $F$ and its parallel cmc surface $F^p$ carry conformally equivalent metrics. In \cite{12} we proved that this behaviour characterizes cmc surfaces: a surface $F : U \to \mathbb{R}^3$ is cmc if and only if its (suitably scaled and positioned) Christoffel transform is a Darboux transform of $F$, too.

Since we are working on Christoffel and Darboux transforms of isothermic surfaces it seems to be reasonable to use this characterization of cmc surfaces as a

**Definition (Discrete cmc net):** An isothermic net $F : \Gamma \to \mathbb{R}^3$ is called a discrete cmc net if a (suitably scaled and positioned) Christoffel transform $F^p : \Gamma \to \mathbb{R}^3$ of $F$ is a Darboux transform of $F$, too.

However, in Euclidean geometry this definition is rather unsatisfactory since it doesn’t say anything about the mean curvature — which is claimed to be constant: recall the meaning of “cmc”. But, according to the above discussions we might define the (constant) mean curvature of a discrete

\footnote{Note that the sphere — which is certainly a surface of constant mean curvature — behaves exceptionally in this context: any Christoffel transform of the sphere is a minimal surface but its “parallel constant mean curvature surface” collapses to the center of the sphere. Therefore, for the sphere, “suitably scaled” means that the scaling factor $\frac{1}{\lambda} = 0$.}

\footnote{Because of the way we introduced the scaling factor $\lambda$ for the Christoffel transform in \cite{9} this definition excludes the sphere: for the sphere the “suitably scaled” Christoffel transform would be the center of the sphere (cf. footnote \cite{13}), i.e. $\lambda = \infty$.}

\footnote{In the geometry of similarities, however, this is a good definition: here, the value of the (constant) mean curvature is not an invariant. Note that the geometry of similarities arises much more naturally (by distinguishing a point at infinity) as a subgeometry of Möbius geometry than the Euclidean geometry (where, additionally, a scaling of the conformal metric has to be chosen).}

\footnote{In our discussions, Alexander Bobenko suggested a definition for the mean curvature function $H : \Gamma \to \mathbb{R}$ of an (arbitrary) discrete net $F : \Gamma \to \mathbb{R}^3$ at a point $F_{m,n}$ of the net: consider the point $C$ which has equal distances $|F_{m-1,n} - C| = |F_{m+1,n} - C|$ and $|F_{m,n-1} - C| = |F_{m,n+1} - C|$ to the pairs of opposite neighbours of $F_{m,n}$ and whose distance to $F_{m,n}$ satisfies $|F_{m,n} - C|^2 = \frac{1}{2}(|F_{m+1,n} - C|^2 + |F_{m,n+1} - C|^2)$. Its reciprocal distance}
Figure 7: A minimal Darboux transform of the Catenoid
cmc net to be the reciprocal of the constant distance (vertex wise) of the nets $F$ and $F^p$ — if we happen to prove the following

**Theorem:** A Christoffel transform $F^c : \Gamma \to \mathbb{R}^3$ of an isothermic net $F : \Gamma \to \mathbb{R}^3$ is a Darboux transform of $F$, too, if and only if the distance $|F^c_{m,n} - F_{m,n}|$ is constant.

Since the quadrilaterals spanned by corresponding edges\[^{17}\] of $F$ and $F^c$ are trapezoids this theorem will be a consequence of

**The Trapezium lemma:** The cross ratio of a trapezoid is real if and only if that trapezoid is isosceles. A quadrilateral $(Q_1, Q_2, Q_3, Q_4) \subset H$ is an (isosceles) trapezoid, i.e. $(Q_1-Q_4) \parallel (Q_2-Q_3)$ (and $|Q_1-Q_2| = |Q_3-Q_4|$), if and only if\[^{18}\]

$$DV(Q_1, Q_2, Q_3, Q_4) = -\frac{|Q_1-Q_3|^2}{|Q_1-Q_3|^2 - |Q_1-Q_2|^2}. \tag{23}$$

It is clear that the four vertices of an isosceles trapezoid lie on a circle and consequently, its cross ratio has to be real. To understand the converse we assume that the vertices of a trapezoid lie on a circle. Then, the four vertices are obtained by intersecting this circle with two parallel lines. Thus, the trapezoid has a reflection symmetry showing that it has to be isosceles. This proves the first part of the trapezium lemma. Since a quadrilateral is uniquely determined by three of its points and its cross ratio the second part becomes clear by calculating the cross ratio (2) of an isosceles trapezoid.

One direction in the proof of the theorem is now obvious: if the Christoffel transform $F^c$ of an isothermic net $F$ is also a Darboux transform, then, $H_{m,n} = |F_{m,n} - C|^{-1}$ can be considered the mean curvature of the net $F$ at $F_{m,n}$. Note, that $C$ may not be a finite point — then the mean curvature vanishes (cf. the definition of discrete minimal surfaces in \[^3\]).

\[^{17}\]Corresponding edges of $F$ and any Christoffel transform $F^c$ are parallel — note that we restricted to the codimension 1 case.

\[^{18}\]Note, that if $|Q_1-Q_2| < |Q_1-Q_3|$ then the trapezoid has legs $Q_1-Q_2$ and $Q_3-Q_4$ and the isosceles trapezoid $(Q_1, Q_2, Q_3, Q_4)$ is embedded. If $|Q_1-Q_2| > |Q_1-Q_3|$ the edges $Q_1-Q_2$ and $Q_3-Q_4$ become the diagonals of the trapezoid which is then not embedded.
all the trapezoids spanned by corresponding edges of $F$ and $F^c$ are isosceles. Thus, $|F_{m,n} - F^c_{m,n}| = |F_{m+1,n} - F^c_{m+1,n}| = |F_{m,n+1} - F^c_{m,n+1}|$. The other direction becomes clear, again, by calculating the cross ratio of an isosceles trapezoid: up to the “correct” scaling factor $\lambda^c$ for the Christoffel transform $F^c$, corresponding edges of $F$ and $F^c$ have reciprocal lengths (9) and consequently, the cross ratios (2) become

\[
\begin{align*}
    \text{DV}(F_{m,n}, F^c_{m,n}, F^c_{m+1,n}, F_{m+1,n}) &= \lambda^c |F_{m,n} - F^c_{m,n}|^2 \\
    \text{DV}(F_{m,n}, F^c_{m,n}, F^c_{m,n+1}, F_{m,n+1}) &= -\lambda^c |F_{m,n} - F^c_{m,n}|^2
\end{align*}
\] (24)

— which proves the theorem.

Now, we are able to give a definition of discrete cmc nets involving the mean curvature:

**Definition (Discrete net of constant mean curvature):** An isothermic net $F: \Gamma \to \mathbb{R}^3$ is a net of constant mean curvature $H$ if there is a Christoffel transform $F^p: \Gamma \to \mathbb{R}^3$ of $F$ in constant distance \(^{20}\)

\[
|F_{n,m} - F^p_{n,m}|^2 = \frac{1}{H^2}.
\] (25)

$F^p$ is called the parallel cmc net of $F$.

Note that this definition is symmetric in $F$ and its Christoffel transform $F^p$. So, by definition, the (correctly scaled) Christoffel transform of a discrete net of constant mean curvature $H$ is a discrete net of constant mean curvature $H$, too. Clearly, rescaling of the Christoffel transform results in a discrete net of (generally) another constant mean curvature. Also note that the sign of the (constant) mean curvature $H$ is not determined in the above definition.\(^{21}\)

\(^{19}\)Moreover, after contemplating the relation between the lengths of the edges and of the diagonals of an isosceles trapezoid we see that also the distances $|F_{m,n} - F^c_{m+1,n}|$ and $|F_{m,n} - F^c_{m,n+1}|$ are constant.

\(^{20}\)As before (cf. footnote \[3\]), the sphere is excluded by this definition.

\(^{21}\)Choosing a sign for the constant mean curvature $H$ would correspond to the choice of a unit normal field $N: \Gamma \to S^2$. Note, that also the definition of the mean curvature function sketched in footnote \[4\] includes no sign choice.

From our previous discussions (cf. footnote \[5\]), it is clear that this mean curvature function (in the sense of footnote \[6\]) indeed, equals the constant $H$ for a “discrete net of constant mean curvature $H$” (in the sense of the above definition).
From the work of Bianchi [1] it is well known that (smooth) cmc surfaces allow $\infty^3$ Darboux transforms in cmc surfaces. In [12] we showed that a constant mean curvature Darboux transform $\hat{F} : U \rightarrow \mathbb{R}^3$ of a constant mean curvature surface $F : U \subset \mathbb{R}^2 \rightarrow \mathbb{R}^3$ has constant distance

$$|\hat{F} - F^p|^2 = \frac{1 - H^c H}{H^2}$$

(26)

to its parallel constant mean curvature surface $F^p$. Herein, the mean curvature $H^c$ of $F^c$ of $F$ is used to determine the scaling of the Christoffel transform in the Riccati equation (17). The 3-parameter family mentioned by Bianchi is obtained by solving the Riccati equation with an initial value satisfying (26). A similar theorem holds in the discrete case — we will obtain it as a consequence of the following

**Supplement to the Hexahedron lemma:** If, in the hexahedron lemma, two of the faces (quadrilaterals) of the constructed hexahedron are (isosceles) trapezoids, then their opposite faces are (isosceles) trapezoids, too.

To prove this supplement let — without loss of generality — the initial quadrilateral $(X_1, X_2, X_3, X_4)$ and the first constructed quadrilateral $(X_1, X_2, Z_2, Z_1)$ be isosceles trapezoids. Calculating the cross ratios of these two trapezoids yields

$$\mu = \pm \frac{|X_1-X_2|^2}{|X_1-X_4||X_2-X_3|}$$
$$\lambda \mu = \pm \frac{|X_1-Z_1|^2}{|X_1-Z_3||X_2-Z_2|}$$

(27)

— where all sign combinations can occur, depending on whether the two trapezoids are embedded or not. The remaining two points $Z_3$ and $Z_4$ have to satisfy the condition

$$DV(X_1, Z_1, Z_4, X_4) = DV(X_2, Z_2, Z_3, X_3) = \lambda.$$  

(28)

In our situation, these two points can be constructed quite explicitly — showing that the quadrilaterals $(X_1, Z_1, Z_4, X_4)$ and $(X_2, Z_2, Z_3, X_3)$ have parallel edges: without loss of generality we may assume that the circles determined by the point triples $\{X_4, X_1, Z_1\}$ and $\{X_3, X_2, Z_2\}$ have the same

---

If two opposite quadrilaterals are trapezoids then there is nothing to prove.
Figure 8: A supplement to the hexahedron lemma

radius. Since \((X_4 - X_1) \parallel (X_3 - X_2)\) and \((X_1 - Z_1) \parallel (X_2 - Z_2)\) we conclude \(|X_4 - Z_1| = |X_3 - Z_2|\) — this argument is sketched in figure 8, in case the first two trapezoids are embedded and in case the initial one is embedded and the second one is not. Thus, we find a reflection which interchanges \(X_4\) with \(Z_2\) and \(X_3\) with \(Z_1\). Now, the two points we had to construct are the images \(Z_4\) of \(X_2\) and \(Z_3\) of \(X_1\) — it is easily checked that the quadrilaterals \((X_1, Z_1, Z_4, X_4)\) and \((X_2, Z_2, Z_3, X_3)\) have the correct cross ratio. Since these quadrilaterals obviously have parallel edges all quadrilaterals \((X_1, X_2, X_3, X_4)\), \((X_1, X_2, Z_2, Z_1)\), \((Z_1, Z_2, Z_3, Z_4)\) and \((X_4, X_3, Z_3, Z_4)\) are trapezoids and since their cross ratios are real they are isosceles. This proves the above supplement to the hexahedron lemma.

With this knowledge we can now prove the announced

**Theorem:** If \(F : \Gamma \to \text{Im} H\) is a discrete net of constant mean curvature \(H\), then any solution \(\hat{F} : \Gamma \to \text{Im} H\) of the Riccati type system (18) with the initial condition

\[
|\hat{F}_{mn} - F_{mn}|^2 = \frac{1}{H^2} \left( 1 - \frac{\lambda}{\lambda^p} \right)
\]

is a discrete net of constant mean curvature \(H\). Herein, \(\lambda^p\) is the parameter of the Darboux transform which transforms the cmc net \(F\) into its parallel cmc net \(F^p\).

To prove this theorem we will have to construct the parallel cmc net \(\hat{F}^p\) of
Figure 9: A Darboux transform of the cylinder
\( \hat{F} \). This net is a \( \lambda^p \)-Darboux transform of \( \hat{F} \) and a \( \lambda \)-Darboux transform of the parallel cmc net \( F^p \) of \( F \) at the same time — consequently, the construction will be similar to that in the proof of the permutability theorem for the Darboux transform (cf. Fig. 6).

By the trapezium lemma, the quadrilateral \((F_{m,n}, F^p_{m,n}, \hat{F}^p_{m,n}, \hat{F}_{m,n})\) which is first constructed is an isosceles trapezoid because of (29). Since all the quadrilaterals spanned by corresponding edges of \( F \) and its parallel cmc net \( F^p \) are also isosceles trapezoids, according to our supplement to the hexahedron lemma, there is a net \( \hat{F}^p : \Gamma \to \text{Im} H \) whose edges are parallel to the corresponding edges of \( \hat{F} \) and which has constant distance \( \frac{1}{|H|} \) to \( \hat{F} \). The only thing left is to show that \( \hat{F}^p \) is a Christoffel transform of \( \hat{F} \)— which becomes clear by contemplating the cross ratios

\[
\begin{align*}
\text{DV}(\hat{F}_{m,n}, \hat{F}^p_{m,n}, \hat{F}^p_{m+1,n}, \hat{F}_{m+1,n}) &= \lambda^p, \\
\text{DV}(\hat{F}_{m,n}, \hat{F}^p_{m,n}, \hat{F}^p_{m,n+1}, \hat{F}_{m,n+1}) &= -\lambda^p;
\end{align*}
\]

since \( |\hat{F}_{m,n} - \hat{F}^p_{m,n}|^2 = \frac{1}{|H|^2} \) it follows

\[
\begin{align*}
(\hat{F}_{m+1,n} - \hat{F}_{m,n})(\hat{F}^p_{m+1,n} - \hat{F}^p_{m,n}) &= -\frac{1}{|H|^2}
\end{align*}
\]

Thus, \( \hat{F}^p \) is a Christoffel transform of \( \hat{F} \) and consequently it is its parallel cmc net in distance \( \frac{1}{|H|} \). This completes the proof.

Now, let’s assume we have two cmc Darboux transforms \( \hat{F}_1 \) and \( \hat{F}_2 \) of a discrete net \( F \) of constant mean curvature \( H \), and their parallel cmc nets \( F^p, \hat{F}^p_1 \) and \( \hat{F}^p_2 \) which are \( \lambda^p \)-Darboux transforms of the original nets. By the “fancy” version of Bianchi’s permutability theorem, the picture gets completed with two discrete isothermic nets \( \hat{F} \) and \( \hat{F}^p \) — \( \hat{F} \) being a \( \lambda_2 \)-Darboux transform of \( \hat{F}_1 \) and a \( \lambda_1 \)-Darboux transform of \( \hat{F}_2 \) and \( \hat{F}^p \) being a \( \lambda^p \)-Darboux transform of \( \hat{F} \), a \( \lambda_1 \)-Darboux transform of \( \hat{F}^p_2 \) and a \( \lambda_2 \)-Darboux transform of \( \hat{F}^p_1 \). Since, moreover, \( F^p \) and \( \hat{F}^p_i \) are the parallel cmc nets of \( F \) and \( \hat{F}_i \) the quadrilaterals \((F, F^p, \hat{F}^p_i, \hat{F}_i)\) and \((F, F^p, \hat{F}^p_2, \hat{F}_2)\) are isosceles trapezoids. Thus, by our supplement to the hexahedron lemma, the quadrilaterals \((\hat{F}_1, \hat{F}^p_1, \hat{F}^p, \hat{F})\) and \((\hat{F}_2, \hat{F}^p_2, \hat{F}^p, \hat{F})\) are isosceles trapezoids, too. Consequently, the net \( \hat{F}^p \) is the parallel cmc net of the cmc net \( \hat{F} \) — we just proved the following permutability theorem for cmc Darboux transforms of discrete cmc nets (cf. [3]):
Theorem: If \( \hat{F}_1, \hat{F}_2 : \Gamma \to \text{Im} H \) are two cmc Darboux transforms of a discrete net \( F : \Gamma \to \text{Im} H \) of constant mean curvature \( H \) with parameters \( \lambda_1 \) and \( \lambda_2 \), respectively, then there exists a net \( \tilde{F} : \Gamma \to \text{Im} H \) of constant mean curvature \( H \) which is a \( \lambda_2 \)-Darboux transform of \( \hat{F}_1 \) and a \( \lambda_1 \)-Darboux transform of \( \hat{F}_2 \) at the same time. The nets \( F, \hat{F}_1, \hat{F}_2 \) and \( \tilde{F} \) have constant cross ratio \( \frac{\lambda_2}{\lambda_1} \equiv \text{DV}(F, \hat{F}_2, \tilde{F}, \hat{F}_1) \).

Acknowledgment: We would like to thank Alexander Bobenko for many fruitful discussions.
