The qualitative analysis of a three-species reaction-diffusion model with a modified Leslie-Gower scheme under the Neumann boundary condition is obtained. The existence and the stability of the constant solutions for the ODE system and PDE system are discussed, respectively. And then, the priori estimates of positive steady states are given by the maximum principle and Harnack inequality. Moreover, the nonexistence of nonconstant positive steady states is derived by using Poincaré inequality. Finally, the existence of nonconstant positive steady states is established based on the Leray-Schauder degree theory.

1. Introduction

Three-species reaction-diffusion models with Holling-type II functional response have been a familiar subject for the analysis. Taking more practical factors into consideration, a model with a modified Leslie-Gower scheme is worthy to explore. Leslie-Gower’s scheme indicates that the carrying capacity of the predator is proportional to the population size of the prey. The existing works [1–3] are all about models with this scheme. As a matter of fact, predators prefer to prey on other prey in the event of a shortage of favorite prey, so the research of the modified Leslie-Gower model springs up. Aziz-Alaoui and Okiye [4] focused on a two-dimensional continuous time dynamical system modeling a predator-prey food chain and gave the main result of the boundedness of solutions, the existence of an attracting set, and the global stability of the coexisting interior equilibrium, which was based on a modified version of the Leslie-Gower scheme and Holling-type II scheme. Singh and Gakkhar [5] investigated the stabilization problem of the modified Leslie-Gower type prey-predator model with the Holling-type II functional response. The analysis of models with a modified Leslie-Gower scheme can be also found in [6–10].

Nonconstant positive steady states have received increasing attention in recent years, see [11–18] and references therein. Ko and Ryu [19] showed that the predator-prey model with Leslie-Gower functional response had no nonconstant positive solution in homogeneous environment, but the system with a general functional response might have at least one nonconstant positive steady state under some conditions. Zhang and Zhao [20] analyzed a diffusive predator-prey model with toxins under the homogeneous Neumann boundary condition, including the existence and nonexistence of nonconstant positive steady states of this model by considering the effect of large diffusivity. Shen and Wei [21] considered a reaction-diffusion mussel-algae model with state-dependent mussel mortality which involved a positive feedback scheme. Wang and his partners [22] considered a tumor-immune model with diffusion and nonlinear functional response and investigated the effect of diffusion on the existence of nonconstant positive steady states and the steady-state bifurcations. Hu and Li [23] were concerned about a strongly coupled diffusive predator-prey system with a modified Leslie-Gower scheme and established the existence of nonconstant positive steady states. Qiu and Guo [24] analyzed a stationary Leslie-Gower model with diffusion and advection.

Motivated by the mentioned above, we consider a three-species reaction-diffusion model with a modified Leslie-Gower and Holling-type II scheme under the homogeneous Neumann boundary condition as follows:
where $u$ and $v$ represent the density of two competitors, respectively, while $w$ stands for the density of the predator who preys on $u$. $A$, $B$, and $C$ are all positive as the intrinsic growth rates, $A_1$ and $A_2$ regard as influencing factors within diverse populations themselves while $B_1$ and $B_2$ are influencing factors between different populations. All of them are nonnegative. $C_1 w/(1 + D_1 u)$ and $C_2 w/(1 + D_2 u)$ are the modified Leslie-Gower scheme, and $C_1$, $C_2$, $D_1$, and $D_2$ are positive. Applying the following scaling to (1), as well as assuming $C_1 D_2/D_1 C_2 = 1$ for simplicity of calculation:

$$m_1 = \frac{D_1}{C_1} u, m_2 = \frac{A_2 D_1}{A_1 C_1} v, m_3 = \frac{D_1}{A_1 C_1} w, s = A_1 C_1,$$

still using $u, v, w, t$ replace $m_1, m_2, m_3, s$, the following ODE system can be logically obtained:

$$\begin{aligned}
\frac{\partial u}{\partial t} &= u \left( a - u - \alpha_1 v - \frac{w}{\beta_1 + u} \right), \\
\frac{\partial v}{\partial t} &= v(b - v - \alpha_2 u), \\
\frac{\partial w}{\partial t} &= w \left( c - \frac{w}{\beta_2 + u} \right),
\end{aligned}$$

$$u(0) \geq 0, v(0) \geq 0, w(0) \geq 0,$$  

where $a = AD_1/A_1 C_1$, $b = BD_1/A_1 C_1$, $c = CD_1/A_1 C_1$, $\alpha_1 = B_1/A_2$, $\alpha_2 = B_2/A_1$, $\beta_1 = 1/C_1$, $\beta_2 = 1/C_2$.  

It is clear that $(0, 0, 0), (a, 0, 0), (0, b, 0), (0, 0, c \beta_2)$, and $(0, b, c \beta_2)$ are nonnegative constant solutions of system (3). $(a - \alpha_1 b)/(1 - \alpha_1 \alpha_2), (b - \alpha_2 a)/(1 - \alpha_1 \alpha_2), 0)$ is a semitrivial solution when it satisfies $(a - \alpha_1 b)(b - \alpha_2 a) > 0$. When $a \beta_1 > c \beta_2$, $(u, 0, 0)$ is a semitrivial solution where

$$u = \frac{a - \beta_1 - c + \sqrt{(\beta_1 - a + c)^2 - 4c \beta_2 + 4a \beta_1}}{2},$$

$$w = c(\beta_2 + u_0).$$

System (3) yields that

$$(\alpha_1 \alpha_2 - 1) a^2 + (a - \beta_1 - \alpha_1 b + \alpha_1 \alpha_2 \beta_1 - c) u + \beta_1 a - \alpha_1 \beta_1 b - \beta_2 c = 0.$$  

If the following alternative conditions hold:

$$\begin{aligned}
(i) \alpha_1 \alpha_2 > 1 &\text{ and } a < \frac{b}{\alpha_2}, \\
(ii) \alpha_1 b + c \beta_2 < a &< \frac{b}{\alpha_2},
\end{aligned}$$

there exists the unique positive equilibrium $(u^*, v^*, w^*)$ as

$$u^* = -a + \alpha_1 \beta_1 b - \alpha_1 \alpha_2 \beta_1 + c + \sqrt{\Delta}$$

$$\frac{2(a \alpha_2 - 1)}{\beta_1},$$

$$v^* = b - \alpha_2 u^*,$$

$$w^* = c(\beta_2 + u^*),$$

where

$$\Delta = (a - \beta_1 - \alpha_1 b + \alpha_1 \alpha_2 \beta_1 - c)^2 - 4(\alpha_1 \alpha_2 - 1)(\beta_1 a - \alpha_1 \beta_1 b - \beta_2 c).$$

Taking the diffusion into account, the corresponding PDE system can be written as

$$\begin{aligned}
\frac{\partial u}{\partial t} - d_1 \Delta u &= u \left( a - u - \alpha_1 v - \frac{w}{\beta_1 + u} \right), \\
\frac{\partial v}{\partial t} - d_2 \Delta v &= v(b - v - \alpha_2 u), \\
\frac{\partial w}{\partial t} - d_3 \Delta w &= w \left( c - \frac{w}{\beta_2 + u} \right),
\end{aligned}$$

$$u(x, 0) = u_0(x), v(x, 0) = v_0(x), w(x, 0) = w_0(x), \quad x \in \Omega,$$

where $\Omega \subset \mathbb{R}^N$ is a smooth bounded domain, $n$ is the outward unit normal vector on $\partial \Omega$, $\Delta$ is the Laplace operator, and diffusion coefficients are $d_1, d_2, d_3 > 0$.  

The rest of this paper is arranged as follows. In Section 2, the stability of constant solutions for the ODE system is discussed. In Section 3, the stability of constant solutions for the PDE system is studied. In Section 4, we focus on the priori estimates of positive steady states. In the last two sections, we have a discussion about the nonexistence and existence of nonconstant positive steady states under different conditions.

2. Stability of Constant Solutions for the ODE System

In this section, we discuss the stability of constant solutions with the condition of their existence for the ODE system.

**Theorem 1.** For the ODE system (3), let $\Gamma = \{a, b, c, \alpha_1, \alpha_2, \beta_1, \beta_2\}$ and $1/(\beta_1 + u^*) \equiv B$.

$$\begin{aligned}
(i) \quad & (0, 0, 0), (a, 0, 0), (0, b, 0), (0, 0, c \beta_2) \quad \text{and} \quad ((a - \alpha_1 b) \\
&/ (1 - \alpha_1 \alpha_2), (b - \alpha_2 a)/(1 - \alpha_1 \alpha_2), 0) \quad \text{are all unconditionally unstable}
\end{aligned}$$
(ii) If \( \Gamma \) satisfies \( a < b/\alpha_2 \), then \((u, 0, \dot{u}, w)\) is unstable; if \( b < a(\alpha - \beta_1 - c) \) holds, \((u, 0, \dot{u}, w)\) is local asymptotically stable.

(iii) If \( \Gamma \) satisfies \( a > \alpha, b + c(\beta_2/\beta_1) \), then \((0, b, c, c)\) is unstable; if \( a < \alpha, b + c(\beta_2/\beta_1) \) holds, \((0, b, c, c)\) is local asymptotically stable.

(iv) If \( \Gamma \) and \( B \) satisfy \( 2u^* - a + (\alpha_1 + 1)(b - \alpha_2u^*) + \beta_1cB(\beta_2 + u^*) + c < 0 \), then \((u^*, v^*, w^*)\) is unstable; if \( 2u^* - a - c \geq 0 \) and \( c - \alpha_1\alpha_2u^* \geq 0 \) holds, \((u^*, v^*, w^*)\) is local asymptotically stable.

Proof. The Jacobian matrix of the ODE system (3) is

\[
J = \begin{pmatrix}
    a - 2u - \alpha u - \frac{\beta_1 w}{(\beta_1 + u)^2} & -\alpha u & -\frac{u}{\beta_1 + u} \\
    -\alpha v & b - \alpha_1u - 2v & 0 \\
    \frac{w^2}{(\beta_2 + u)^2} & 0 & c - \frac{2w}{\beta_2 + u}
\end{pmatrix}.
\]

(12)

Obviously, we can obtain

\[
J = \begin{pmatrix}
    a & 0 & 0 \\
    0 & b & 0 \\
    0 & 0 & c
\end{pmatrix}
\]

(13)

at \((0, 0, 0)\) and its corresponding characteristic polynomial is

\[
\varphi(\lambda) = (\lambda - a)(\lambda - b)(\lambda - c) = 0,
\]

(14)

so its eigenvalues are \( \lambda_1 = a > 0, \lambda_2 = b > 0, \) and \( \lambda_3 = c > 0 \). Therefore, \((0, 0, 0)\) is unstable to system (3).

By the same manner, we know that \((a, 0, 0), (0, b, 0), (0, 0, c), \) and \((\alpha_1 - \alpha_2)/(1 - \alpha_1, \alpha_2), (b - \alpha_2a)/(1 - \alpha_1, \alpha_2), \) are all unstable to ODE system (3).

The Jacobian matrix of the ODE system at \((\dot{u}, 0, \dot{u}, \dot{u})\) is

\[
J = \begin{pmatrix}
    -\dot{u} + \frac{\dot{u}(a - \dot{u})}{\beta_1 + \dot{u}} & -\alpha_1 \dot{u} & -\frac{\dot{u}}{\beta_1 + \dot{u}} \\
    0 & b - \alpha_2 \dot{u} & 0 \\
    c^2 & 0 & -c
\end{pmatrix}.
\]

(15)

The characteristic polynomial is

\[
[\lambda - (b - \alpha_2 \dot{u})] \left( \frac{\lambda + \dot{u}(a - \dot{u})}{\beta_1 + \dot{u}} + c^2 \frac{\dot{u}}{\beta_1 + \dot{u}} \right) = 0.
\]

(16)

When the eigenvalue satisfies \( \lambda_1 = b - \alpha_2 \dot{u} > 0 \), it deduces that \( a < b/\alpha_2 \), so we can see that \((\dot{u}, 0, \dot{u}, \dot{u})\) is unstable to ODE system (3). When \( \lambda_1 = b - \alpha_2 \dot{u} < 0 \), we consider that

\[
\lambda^2 + \left( \frac{\dot{u}(a - \dot{u})}{\beta_1 + \dot{u}} + c \right) \lambda + \dot{u} - \frac{c \dot{u}(a - \dot{u})}{\beta_1 + \dot{u}} + \frac{c^2 \dot{u}}{\beta_1 + \dot{u}} = 0.
\]

(17)

Let \( p_1 = \dot{u} - (\dot{u}(a - \dot{u})/(\beta_1 + \dot{u}) + c, p_2 = \dot{u} - (\dot{u}(a - \dot{u})/(\beta_1 + \dot{u}) + \dot{u}) \dot{u} + \dot{u}, p_2 = ((\dot{u}(a - \dot{u})/(\beta_1 + \dot{u}) + c - a)/(\beta_1 + \dot{u}) > 0 \). With the existence condition \( \alpha_1 > \alpha_2, \lambda_1 > 0 \) and \( p_2 > 0 \) hold, such that equation (17) has two solutions with negative real parts.

Because of \( \alpha_1 > \alpha_2 \),

\[
\lambda_1 = b - \alpha_2 \dot{u} = b - \alpha_2 \dot{u} + \sqrt{(b - a + c)^2 - 4c2 + 4a\beta_1}
\]

\[
< b - \alpha_2 \dot{u} + \sqrt{(b - a + c)^2}
\]

(18)

holds, then \( \lambda_1 < 0 \) if \( b - \alpha_2(a - \beta_1 - c) < 0 \). So we can conclude that when \( b < \alpha_2(a - \beta_1 - c) \), \((\dot{u}, 0, \dot{u})\) is local asymptotically stable to ODE system (3).

The Jacobian matrix of the ODE system at \((0, b, c, c)\) is

\[
J = \begin{pmatrix}
    a - \alpha_1b - c & 0 & 0 \\
    -\alpha_2b & -b & 0 \\
    c^2 & 0 & -c
\end{pmatrix}.
\]

(19)

The characteristic polynomial is

\[
(\lambda - a - \alpha_1b - c) (\lambda + b) (\lambda + c) = 0.
\]

(20)

The corresponding eigenvalues are \( \lambda_1 = a - \alpha_1b - c(\beta_2/\beta_1) \), \( \lambda_2 = b < 0, \lambda_3 = -c < 0 \). If \( a > \alpha_1b + c(\beta_2/\beta_1) \), \((0, b, c, c)\) is unstable. Otherwise, \( a < \alpha_1b + c(\beta_2/\beta_1) \), \((0, b, c, c)\) is local asymptotically stable to ODE system (3).

The Jacobian matrix of the ODE system at \((u^*, v^*, w^*)\) is

\[
J = \begin{pmatrix}
    a_{11} & a_{12} & a_{13} \\
    a_{21} & a_{22} & a_{23} \\
    a_{31} & a_{32} & a_{33}
\end{pmatrix}
\]

\[
= \begin{pmatrix}
    a_{11} - 2u^* - a_1(b - \alpha_2u^*) - \beta_1cB(\beta_2 + u^*) - c_1u^* - u^*B \\
    -\alpha_2(b - \alpha_2u^*) & -b + \alpha_2u^* & 0 \\
    c_1 & 0 & -c
\end{pmatrix}.
\]

(21)

The corresponding characteristic polynomial is \( \lambda^3 + A_1 \lambda^2 + A_2 \lambda + A_3 = 0 \), where
When $\Gamma$ satisfies $2u^* - a + (\alpha_1 + 1)(b - \alpha_2 u^*) + \beta_1 c B^2(\beta_2 + u^*) + c < 0$, then $A_1 < 0$, $(u^*, v^*, w^*)$ is unstable applying the Hurwitz criterion [25]. When $2u^* - a - c > 0, c - \alpha_1 \beta_2 u^* \geq 0$, we can find $A_1 > 0, A_2 > 0, A_3 > 0, A_1 A_2 - A_3 > 0$. So $(u^*, v^*, w^*)$ is local asymptotically stable to ODE system (3).

The proof is complete.

3. Stability of Constant Solutions for the PDE System

In this section, the stability of the constant solutions with the condition of their existence for the PDE system is discussed. Let $0 = \mu_0 < \mu_1 < \mu_2 < \cdots$ as the eigenvalues of the operator $-\Delta$ over $\Omega$ under the homogeneous Neumann boundary condition and $E(\mu_j)$ be the corresponding eigen-space while $\{\varphi_{ij} : j = 1, 2, \cdots, \dim E(\mu_j)\}$ is a set of the orthogonal basis of $E(\mu_j), X = \{U \in C^1(\Omega) \times C^1(\Omega) | \partial_u U = 0, x \in \partial \Omega, X_{ij} = \{c \varphi_{ij} | c \in R^3\}$. Then, $X = \oplus_{i=0}^{\infty} \oplus_{j=1}^{\dim E(\mu_j)} X_{ij}$.

Theorem 2. For the PDE system (11), let $\Gamma = \{a, b, c, \alpha_1, \alpha_2, \beta_1, \beta_2\}$ and $1/(\beta_1 + u^*) \in \mathbb{C}^+$. Let

$$
\begin{aligned}
A_1 &= 2u^* - a + (\alpha_1 + 1)(b - \alpha_2 u^*) + \beta_1 c B^2(\beta_2 + u^*) + c, \\
A_2 &= \left[ a - 2u^* - \alpha_1 (b - \alpha_2 u^*) - \beta_1 c B^2(\beta_2 + u^*) \right](\alpha_2 u^* - b - c) + c^2 u^* B + (\alpha_1 \alpha_2 u^* - c)(\alpha_2 u^* - b), \\
A_3 &= c(\alpha_2 u^* - b) \left[ a - 2u^* - \alpha_1 (b - 2\alpha_2 u^*) - \beta_1 c B^2(\beta_2 + u^*) - cu^* B \right].
\end{aligned}
$$

(i) $(0, 0, 0), (a, 0, 0), (b, 0, 0), (0, 0, cB^2)$ and $(a - \alpha_1 b)/(1 - \alpha_1 \alpha_2), (b - \alpha_2 a)/(1 - \alpha_1 \alpha_2), 0$ are all conditionally unstable

(ii) If $\Gamma$ satisfies $a < b / \alpha_2$, then $(\dot{u}, 0, \dot{w})$ is unstable; if $b < \alpha_2(a - \beta_1 - c)$ and $d_1/d_3 > (a + \beta_2) / \beta_1$ holds, $(\dot{u}, 0, \dot{w})$ is uniformly asymptotically stable

(iii) If $\Gamma$ satisfies $a > \alpha_1 b + c \beta_2 / \beta_1$, then $(0, 0, cB^2)$ is unstable; if $a < \alpha_1 b + c \beta_2 / \beta_1$ holds, $(0, 0, cB^2)$ is uniformly asymptotically stable

(iv) If $B$ and $B$ satisfy $2u^* - a + (\alpha_1 + 1)(b - \alpha_2 u^*) + \beta_1 c B^2(\beta_2 + u^*) + c < 0$, then $(u^*, v^*, w^*)$ is unstable; if $2u^* - a - c > 0$ and $c - \alpha_1 \beta_2 u^* \geq 0$ holds, $(u^*, v^*, w^*)$ is uniformly asymptotically stable

Proof: The linearization of (11) at the positive constant solution $U^*$ can be expressed by $U = (D\Delta + G_U(U^*)) U$ where $U = (u, v, w)^T, U^* = (u^*, v^*, w^*)^T, D = \text{diag}(d_1, d_2, d_3)$ and $G_U(U^*)$ is the Jacobian matrix at $U^*$. For each $i \geq 0$, $\oplus_{j=1}^{\dim E(\mu_j)} X_{ij}$ is invariant under the operator $D\Delta + G_U(U^*)$.

And $\lambda$ is an eigenvalue of $D\Delta + G_U(U^*)$ on $\oplus_{j=1}^{\dim E(\mu_j)} X_{ij}$ if and only if $\lambda$ is an eigenvalue of the matrix $-\mu_1 D + G_U(U^*)$.

The Jacobian matrix of PDE system (11) is

$$
J = \begin{pmatrix}
\frac{a - 2u - \alpha_1 v}{(\beta_1 + u)} - d_1 \mu_i & -\alpha_1 u & -\frac{u}{\beta_1 + u} \\
-\frac{\alpha_1 v}{(\beta_1 + u)} & \frac{b - \alpha_2 u - 2v - d_2 \mu_i}{\beta_1 + u} & 0 \\
\frac{\alpha_1 v}{(\beta_1 + u)} & \frac{c^2}{\beta_1 + u} & \frac{-c - d_3 \mu_i}{(\beta_1 + u)}
\end{pmatrix}.
$$

The characteristic polynomial is

$$
\lambda \left\{ \left( \lambda + \frac{\dot{u}(a + \dot{u})}{\beta_1 + \dot{u}} + d_1 \mu_i \right) \left( \lambda + c + d_3 \mu_i \right) + \frac{c^2 \dot{u}}{\beta_1 + \dot{u}} \right\} = 0.
$$

When the eigenvalue satisfies $\lambda_1 = b - \alpha_2 \dot{u} < 0$, it deduces that $a < b / \alpha_2$, there exists an eigenvalue with positive real part, and $(\dot{u}, 0, \dot{w})$ is unstable to PDE system (11).

It is clear that eigenvalue $\lambda_{1f} = b - \alpha_2 \dot{u} - d_3 \mu_i < 0$ as $\lambda_1 = b - \alpha_2 \dot{u} < 0$. Then, we discuss the following equation emphatically:
\[\lambda^2 + \left( \hat{u} - \frac{\hat{u}(a - \hat{u})}{\beta_1 + \hat{u}} + d_1 \mu_i + c + d_3 \mu_i \right) \lambda + \left( \hat{u} - \frac{\hat{u}(a - \hat{u})}{\beta_1 + \hat{u}} + d_1 \mu_i \right) \left( c + d_3 \mu_i \right) + \frac{c^2 \hat{u}}{\beta_1 + \hat{u}} = 0. \]  

(26)

Let

\[ p_3 = \hat{u} - \frac{\hat{u}(a - \hat{u})}{\beta_1 + \hat{u}} + d_1 \mu_i + c + d_3 \mu_i = (d_1 + d_3) \mu_i + p_1, \]

\[ p_4 = \left( \hat{u} - \frac{\hat{u}(a - \hat{u})}{\beta_1 + \hat{u}} + d_1 \mu_i \right) \left( c + d_3 \mu_i \right) + \frac{c^2 \hat{u}}{\beta_1 + \hat{u}} \]

\[ = d_1 d_3 \mu_i^2 + \left[ c d_1 + \left( \frac{\hat{u}(a - \hat{u})}{\beta_1 + \hat{u}} \right) d_3 \right] \mu_i + p_2. \]

(27)

It shows that \( p_3 > 0 \) on account of \( p_1 > 0 \). When \( c d_1 + |\hat{u} - ((a(\hat{u} - \hat{u}))/ (\beta_1 + \hat{u}))| d_3 > 0 \), we know \( p_4 > 0 \) holds. So the eigenvalues all have negative real parts.

\[ G_U(U^*) = \begin{pmatrix} a - 2u^* - \alpha_1 (b - \alpha_2 u^*) - \beta_1 c B^2 (\beta_2 + u^*) - d_1 \mu_i & -\alpha_1 u^* & -\alpha_1 u^* B \\ -\alpha_2 (b - \alpha_2 u^*) & -b + \alpha_2 u^* - d_2 \mu_i & 0 \\ c^2 & 0 & -c - d_3 \mu_i \end{pmatrix}. \]

(30)

Its characteristic polynomial is \( \lambda^3 + A_{1\mu} \lambda^2 + A_{2\mu} \lambda + A_{3\mu} = 0 \), where

\[ A_{1\mu} = (d_1 + d_2 + d_3) \mu_i + A_1, \]

\[ A_{2\mu} = (d_1 d_2 + d_1 d_3 + d_2 d_3) \mu_i^2 - (d_1 a_{22} + d_2 a_{11} + d_3 a_{13} + d_3 a_{33} + d_3 a_{22}) \mu_i + A_2, \]

\[ A_{3\mu} = d_1 d_2 d_3 \mu_i^3 - (d_1 d_2 a_{33} + d_1 d_3 a_{22} + d_2 d_3 a_{11}) \mu_i^2 + (d_1 a_{11} a_{22} + d_2 a_{11} a_{33} + d_2 a_{11} a_{22} + d_2 a_{33} + d_3 a_{22} a_{33} + d_3 a_{13} a_{33} - d_3 a_{13} a_{31}) \mu_i + A_3. \]

(31)

When \( 2u^* - a + (\alpha_1 + 1)(b - \alpha_2 u^*) + \beta_1 c B^2 (\beta_2 + u^*) + c < 0 \), there exists an eigenvalue with positive real part; \( (u^*, v^*, w^*) \) is unstable to PDE system (11).

When \( A_1 > 0 \) and \( d_1, d_2, d_3 > 0, A_{1\mu} > 0 \) holds. Similarly, \( A_{2\mu} > 0 \) since \( A_2 > 0 \) and \( d_1, d_2, d_3 > 0 \). If \( 2u^* - a - c > 0, c - \alpha_2 u^* \geq 0 \), we have \( d_1 a_{11} a_{22} + d_2 a_{11} a_{33} + d_3 a_{22} a_{33} - d_2 a_{13} a_{31} - d_3 a_{13} a_{31} > 0 \) and \( d_1 d_2 a_{33} + d_1 d_3 a_{22} + d_2 d_3 a_{11} < 0 \). As a result of \( A_3 > 0 \) and \( d_1, d_2, d_3 > 0, A_{3\mu} > 0 \) can be obtained. What is more, \( A_1 A_2 - A_3 > 0 \) leads to \( A_{1\mu} A_{2\mu} - A_{3\mu} > 0 \). Thus, the eigenvalues all have negative real parts.

In the following, we shall prove that there exists a positive constant \( \kappa \) when the corresponding eigenvalues all have negative real parts, such that

\[ \Re \left( \lambda_{1\mu} \right), \Re \left( \lambda_{2\mu} \right), \Re \left( \lambda_{3\mu} \right) < -\kappa, \text{ for all } i \geq 1. \]

(32)

Let \( \lambda = \mu \xi \), then

\[ \psi_i(\lambda) = \mu_i^3 \xi^3 + A_{1\mu} \mu_i^2 \xi^2 + A_{2\mu} \mu_i \xi + A_{3\mu} \xi^2 = \psi_i(\xi). \]

(33)
Since $\mu_1 \to -\infty$ as $i \to \infty$, it follows that

$$
\lim_{i \to \infty} \left\{ \frac{\psi'(\zeta)}{\zeta^i} \right\} = \zeta^3 + (d_1 + d_2 + d_3)\zeta^2 + (d_1d_2 + d_1d_3 + d_2d_3)\zeta + d_1d_2d_3 \geq \psi'(\zeta).
$$

(34)

Applying the Hurwitz criterion, the three roots $\zeta_1, \zeta_2, \zeta_3$ of $\psi'(\zeta) = 0$ all have negative real parts. Thus, there exists a positive constant $\kappa'$ such that $\Re (\zeta_1), \Re (\zeta_2), \Re (\zeta_3) \leq -\kappa'$. By continuity, there exists $t_0$ such that the three roots $\zeta_{i1}, \zeta_{i2}, \zeta_{i3}$ of $\psi(\zeta) = 0$ satisfy

$$
\Re \{\zeta_{i1}\}, \Re \{\zeta_{i2}\}, \Re \{\zeta_{i3}\} \leq -\frac{\kappa'}{2}, \quad \text{for all } i \geq t_0. \quad (35)
$$

Hence, $\Re (\lambda_{i1}), \Re (\lambda_{i2}), \Re (\lambda_{i3}) \leq -\mu_i \kappa'/2 \leq -\kappa'/2$ for all $i \geq t_0$.

Let $-\kappa'' = \max \{\Re (\lambda_{i1}), \Re (\lambda_{i2}), \Re (\lambda_{i3})\}.$ Then, for $i \geq 1$,

$$
\Re (\lambda_{i1}), \Re (\lambda_{i2}), \Re (\lambda_{i3}) < -\kappa. \quad (36)
$$

Therefore, the constant solutions are uniformly asymptotically stable when the corresponding eigenvalues all have negative real parts.

The proof is complete.

4. A Priori Estimates of Positive Steady States

The corresponding steady-state problem of system (11) is

$$
\begin{cases}
-d_1 \Delta u = u \left(a - u - \alpha_1 v - \frac{w}{\beta_1 + u}\right), & x \in \Omega, \\
-d_2 \Delta v = v \left(b - v - \alpha_2 u\right), & x \in \Omega, \\
-d_3 \Delta w = w \left(c - \frac{w}{\beta_2 + u}\right), & x \in \Omega, \\
\frac{\partial u}{\partial n} - \frac{\partial v}{\partial n} + \frac{\partial w}{\partial n} = 0, & x \in \partial \Omega.
\end{cases} \quad (37)
$$

Two lemmas are listed here for the preliminary.

**Lemma 3.** (Harnack inequality [26]).

Let $\omega(x) \in C^2(\Omega) \cap C^1(\bar{\Omega})$ be a positive solution to $\Delta \omega + c(x) \omega = 0, \ x \in \Omega$, where $c(x) \in C(\bar{\Omega})$, satisfying the homogeneous Neumann boundary condition. Then, there exists a positive constant $C_* = C_*(N, \Omega, \|c\|_{\infty})$ such that

$$
\max_{\Omega} \omega \leq C_* \min_{\Omega} \omega. \quad (38)
$$

**Lemma 4.** (maximum principle [27]).

Suppose that $g \in C(\bar{\Omega} \times R^3)$ and $b_j \in C(\bar{\Omega}), j = 1, 2, \cdots, N$.

(i) if $\omega(x) \in C^2(\Omega) \cap C^1(\bar{\Omega})$ satisfies

$$
\Delta \omega + \sum_{j=1}^{N} b_j(x) \omega_{x_j} + g(x, \omega(x)) \geq 0, \quad x \in \Omega,
$$

$$
\frac{\partial \omega}{\partial \nu} \leq 0, \quad x \in \partial \Omega,
$$

and $\omega(x_0) = \max_{\Omega} \omega(x)$, then $g(x_0, \omega(x_0)) \geq 0.$

(ii) if $\omega(x) \in C^2(\Omega) \cap C^1(\bar{\Omega})$ satisfies

$$
\Delta \omega + \sum_{j=1}^{N} b_j(x) \omega_{x_j} + g(x, \omega(x)) \leq 0, \quad x \in \Omega,
$$

$$
\frac{\partial \omega}{\partial \nu} \geq 0, \quad x \in \partial \Omega,
$$

and $\omega(x_0) = \min_{\Omega} \omega(x)$, then $g(x_0, \omega(x_0)) \leq 0.$

Theorem 5. (upper bounds).

Assuming that $(u, v, w)$ is a positive solution of system (37), we get

$$
\max_{\Omega} u \leq a, \quad (41)
$$

$$
\max_{\Omega} v \leq b, \quad (42)
$$

$$
\max_{\Omega} w \leq c(\beta_2 + a). \quad (43)
$$

Proof. Since $u(a - u - \alpha_1 v - w/(\beta_1 + u)) \leq u(a - u)$ and $v(b - v - \alpha_2 u) \leq v(b - v)$, such that $\max_{\Omega} u \leq a, \max_{\Omega} v \leq b$ according to Lemma 4. Because of $\max_{\Omega} u \leq a$, it is evident that $\max_{\Omega} w \leq c(\beta_2 + a)$.

The proof is complete.

Theorem 6. (lower bounds).

Fix $d_1$ and $d_2, d_3$ as positive constants. Assume that

$$
(d_1, d_2, d_3) \in [d_1, \infty) \times [d_2, \infty) \times [d_3, \infty), \quad (44)
$$

then there exists a positive constant $C = C(\Gamma, \Omega, N, d_1, d_2, d_3)$ who can make every positive solution $(u, v, w)$ of system (37) satisfy

$$
\min_{\Omega} u(x) > \bar{C}, \quad (45)
$$

$$
\min_{\Omega} v(x) > \bar{C}, \quad (46)
$$

$$
\min_{\Omega} w(x) > \bar{C}, \quad (47)
$$
\[
\min_{\Omega} w(x) > C. \tag{47}
\]

**Proof.** Let

\[
\begin{align*}
  c_1(x) &= d_1^{-1} \left( a - u - \alpha_1 v - \frac{w}{\beta_1 + u} \right), \\
  c_2(x) &= d_2^{-1} \left( b - v - \alpha_2 u \right), \\
  c_3(x) &= d_3^{-1} \left( c - \frac{w}{\beta_2 + u} \right).
\end{align*} \tag{48}
\]

In view of (41), (42), and (43), a positive constant \( \bar{C} = \bar{C} (\Omega, N, D, \Gamma) \) can be easily found, such that

\[
\|c_1(x)\|_{C^0}, \|c_2(x)\|_{C^0}, \|c_3(x)\|_{C^0} \leq \bar{C}, \tag{49}
\]

where \( d_1, d_2, d_3 > \bar{D} \). Thus, \( u, v, \) and \( w \) satisfy that

\[
\begin{align*}
  \Delta u + c_1(x) u &= 0, \quad x \in \Omega, \\
  \frac{\partial u}{\partial n} &= 0, \quad x \in \partial \Omega, \\
  \Delta v + c_2(x) v &= 0, \quad x \in \Omega, \\
  \frac{\partial v}{\partial n} &= 0, \quad x \in \partial \Omega, \\
  \Delta w + c_3(x) w &= 0, \quad x \in \Omega, \\
  \frac{\partial w}{\partial n} &= 0, \quad x \in \partial \Omega.
\end{align*} \tag{50}
\]

According to the Harnack inequality in Lemma 3, there must be a positive constant \( C_* = C_* (\Omega, N, D, \Gamma) \), such that

\[
\begin{align*}
  \max_{\Omega} u &\leq C_* \min_{\Omega} u, \\
  \max_{\Omega} v &\leq C_* \min_{\Omega} v, \\
  \max_{\Omega} w &\leq C_* \min_{\Omega} w. \tag{51}
\end{align*}
\]

Suppose that (45), (46), and (47) hold of no account. There must be a sequence \( \{(d_{1i}, d_{2i}, d_{3i})\}_{i=1}^{\infty} \) with \( (d_{1i}, d_{2i}, d_{3i}) \in [d_1, \infty) \times [d_2, \infty) \times [d_3, \infty) \), such that the corresponding positive solutions \((u_i, v_i, w_i)\) of system (37) reach the qualification

\[
\max_{\Omega} u_i \to 0, \quad \max_{\Omega} v_i \to 0 \quad \text{or} \quad \max_{\Omega} w_i \to 0 \quad \text{as} \quad i \to \infty. \tag{52}
\]

Then, we apply \((u_i, v_i, w_i)\) to the system of (37) and integrate by parts, so we obtain that

\[
\begin{align*}
  \int_{\Omega} u_i \left( a - u_i - \alpha_1 v_i - \frac{w_i}{\beta_1 + u_i} \right) dx &= 0, \\
  \int_{\Omega} v_i (b - v_i - \alpha_2 u_i) dx &= 0, \tag{53}
\end{align*}
\]

There exists a subsequence of \( \{(d_{1i}, d_{2i}, d_{3i})\}_{i=1}^{\infty} \) according to the \( L^p \)-regularity theory and Sobolev embedding theorem, but we still use \( \{(d_{1i}, d_{2i}, d_{3i})\}_{i=1}^{\infty} \) to represent for convenience. So there must be \( u^*, v^*, w^* \) and \((\bar{d}_1, \bar{d}_2, \bar{d}_3)\) as the limiting of \((u_i, v_i, w_i)\) and \((d_{1i}, d_{2i}, d_{3i})\) when \( i \to \infty \). They can be written as follows:

\[
(u_i, v_i, w_i) \to (u^*, v^*, w^*) \in C^2(\Omega) \times C^2(\Omega) \times C^2(\Omega),
\]

\[(d_{1i}, d_{2i}, d_{3i}) \to (\bar{d}_1, \bar{d}_2, \bar{d}_3) \in [d_1, \infty) \times [d_2, \infty) \times [d_3, \infty). \tag{54}
\]

Let \( i \to \infty \), we get that

\[
\begin{align*}
  \int_{\Omega} u^* \left( a - u^* - \alpha_1 v^* - \frac{w^*}{\beta_1 + u^*} \right) dx &= 0, \\
  \int_{\Omega} v^* (b - v^* - \alpha_2 u^*) dx &= 0, \\
  \int_{\Omega} w^* \left( c - \frac{w^*}{\beta_2 + u^*} \right) dx &= 0.
\end{align*} \tag{55}
\]

We now discuss the following three cases.

**Case 1.** \( u^* \equiv 0 \). Since \( v_i \to v^* \) as \( i \to \infty \), \( b - v_i - \alpha_2 u_i > 0 \), \( x \in \Omega \) holds for every \( i \gg 1 \), so that

\[
\int_{\Omega} v_i (b - v_i - \alpha_2 u_i) dx > 0, \tag{56}
\]

which contradicts with (55).

**Case 2.** \( v^* \equiv 0, u^* \neq 0 \). Since \( u_i \to u^* \) as \( i \to \infty \), \( a - u_i - \alpha_1 v_i - w_i/(\beta_1 + u_i) > 0 \), \( x \in \Omega \) holds for every \( i \gg 1 \), so that

\[
\int_{\Omega} u_i \left( a - u_i - \alpha_1 v_i - \frac{w_i}{\beta_1 + u_i} \right) dx > 0, \tag{57}
\]

which contradicts with (55).

**Case 3.** \( w^* \equiv 0, u^* \neq 0, v^* \neq 0 \). Since \( w_i \to w^* \) as \( i \to \infty \), \( c - w_i/(\beta_2 + u_i) > 0 \), \( x \in \Omega \) holds for every \( i \gg 1 \), so that

\[
\int_{\Omega} w_i \left( c - \frac{w_i}{\beta_2 + u_i} \right) dx > 0, \tag{58}
\]

which contradicts with (55).
The proof is complete.

5. Nonexistence of Nonconstant Positive Steady States

We prove the nonexistence of nonconstant positive steady states of system (37) in this section.

**Theorem 7.** Let \( \mu_1 \) be the smallest positive eigenvalue of operator \(-\Delta\) over \( \Omega \) under the homogeneous Neumann boundary conditions and fixed positive constants \( d_2^*, d_3^* \) satisfy \( \mu_1 d_2^* > b \) and \( \mu_1 d_3^* > c + 1 \), then there exists a positive constant \( D_1 = D_1(\Gamma, d_2^*, d_3^*) \) such that when \( d_1 > D_1 \), \( d_2 \geq d_2^* \) and \( d_3 \geq d_3^* \), system (37) has no nonconstant positive steady states.

**Proof.** Assume that \((u, v, w)\) is the positive solution of (37). For any \( \phi \in L^1(\Omega) \), let \( \phi = (1/|\Omega|) \int_\Omega \phi \, dx \). The differential equation (37) multiplies \( u - \bar{u}, v - \bar{v}, w - \bar{w} \) and integrates by parts over \( \Omega \) to get

\[
\int_\Omega d_1 |\nabla u|^2 \, dx = \int_\Omega u \left( a - u - \alpha_1 v - \frac{w}{\beta_1 + u} \right) - u \left( a - u - \alpha_1 v - \frac{w}{\beta_1 + u} \right) (u - u) \, dx
\]

\[
= \int_\Omega [a(u - u)^2 - (u + u)(u - u)^2] - \alpha_1(uv - u)(u - u) - \frac{uw(\beta_1 + u)(u - u) - uw(\beta_1 + u)(u - u)}{\beta_1(u + \beta_1 + u)} \, dx,
\]

\[
\int_\Omega d_1 |\nabla u|^2 \, dx = \frac{\mu_1}{\int_\Omega |\nabla f|^2 \, dx},
\]

\[
\int_\Omega d_2 |\nabla v|^2 \, dx = \int_\Omega [v(b - v - \alpha_2 u) - \bar{v}(b - v - \alpha_2 u)] \, dx
\]

\[
\int_\Omega d_3 |\nabla w|^2 \, dx = \int_\Omega \left[ \int_\Omega \left[ c - \frac{w}{\beta_2 + u} \right] - \frac{w}{\beta_2 + u} \right] \, dx
\]

Combine (59), (60), and (61), we have

\[
\int_\Omega (d_1 |\nabla u|^2 + d_2 |\nabla v|^2 + d_3 |\nabla w|^2) \, dx
\]

\[
\leq \int_\Omega [a(u - u)^2 + b(v - v)^2 + c(w - w)^2 + (\alpha_1 u + \alpha_2 v) |u - u| |v - v| + (1 + \frac{w^2}{\beta_1^2}) |u - u| |w - w|] \, dx
\]

\[
\leq \int_\Omega \left[ a + \frac{\alpha_1 a + \alpha_2 b}{2} + 1 + \frac{c^2(\beta_2 + a)^2}{2\epsilon_1 \beta_2^2} \right] \cdot (u - u)^2 \, dx
\]

\[
+ \frac{\epsilon_1 (a + \alpha_2 b)}{2} (v - v)^2 \, dx
\]

\[
+ \frac{\epsilon_2 c^2(\beta_2 + a)^2}{2\beta_2^2} (w - w)^2 \, dx,
\]

where \( \epsilon_1, \epsilon_2 \) are the arbitrary small positive constants arising from Young inequality. Meanwhile, applying the Poincaré inequality \( \mu_1 \int_\Omega (f - \bar{f})^2 \, dx \leq \int_\Omega |\nabla f|^2 \, dx \), we gain that

\[
\int_\Omega d_1 |u - \bar{u}|^2 + d_2 |v - \bar{v}|^2 + d_3 |w - \bar{w}|^2 \, dx
\]

\[
\leq \int_\Omega [a + 1 + C^*_1(\epsilon_1, \epsilon_2)] |u - \bar{u}|^2 \, dx
\]

\[
+ \frac{\epsilon_1 (a + \alpha_2 b)}{2} (v - \bar{v})^2 \, dx
\]

\[
+ \frac{\epsilon_2 c^2(\beta_2 + a)^2}{2\beta_2^2} (w - \bar{w})^2 \, dx
\]

for some positive constants \( C^*_1(\epsilon_1, \epsilon_2) \). Choose \( \epsilon_1, \epsilon_2 > 0 \) very small such that

\[
\mu_1 d_2^* \geq b + \frac{\epsilon_1 (a + \alpha_2 b)}{2},
\]

\[
\mu_1 d_3^* \geq c + \frac{\epsilon_2 c^2(\beta_2 + a)^2}{2\beta_2^2}.
\]

Hence, (65) implies that \( v = \bar{v} = \text{constant}, w = \bar{w} = \text{constant}, \) and \( u = \bar{u} = \text{constant} \) if \( d_1 > D_1 \equiv \mu_1^* [a + 1 + C^*_1(\epsilon_1, \epsilon_2)] \).

The proof is complete.

6. Existence of Nonconstant Positive Steady States

In this part, we discuss the existence of nonconstant positive solutions of (37) by using the degree theorem.

Fix the \( \Gamma, d_1, d_3 \) still as positive number and define \( X^+ = \{ U \in X \mid U > 0, x \in \Omega, i = 1, 2, 3 \}, B(i) = \{ U \in X \mid l^{-1} < u, v, w < l, x \in \Omega \}, l > 0 \). Then, (37) can be noted as
\begin{align}
\begin{cases}
-D\Delta U = G(U), & x \in \Omega, \\
\frac{\partial U}{\partial n} = 0, & x \in \partial \Omega.
\end{cases}
\end{align}
\tag{66}

So $U$ is a positive solution to (37) if and only if
\[ F(U) \equiv U - (I - \Delta)^{-1} \{ D^{-1} G(U) + U \} = 0, \quad U \in \mathbf{X}, \tag{67} \]

where $(I - \Delta)^{-1}$ is the inverse of $I - \Delta$ in $\mathbf{X}$ under the homogeneous Neumann boundary condition. And if $F(U) \neq 0$ on $\partial B$, the Leray-Schauder degree $\text{deg}(F(\cdot), 0, B)$ can be well defined. Besides, we note that
\[ D_U F(U^*) \equiv I - (I - \Delta)^{-1} \{ D^{-1} G_U(U^*) + I \}. \tag{68} \]

The index of $F(U)$ at $U^*$ can be either 1 or -1 if $D_U F(U^*)$ is invertible, which is defined as index($F(\cdot), U^*) = (-1)^r$, where $r$ is the total number of eigenvalues with negative real parts of $D_U F(U^*)$.

Let $\lambda$ be an eigenvalue of $D_U F(U^*)$ on $X_{ij}$ for each integer $i \geq 1$ and each integer $1 \leq j \leq \dim E(\mu)$, if and only if it is an eigenvalue of the matrix
\[
I - \frac{1}{1 + \mu_i} \left[ D^{-1} G_U(U^*) + I \right] = \frac{1}{1 + \mu_i} \left[ \mu_i I - D^{-1} G_U(U^*) \right].
\tag{69}
\]

Hence, $D_U F(U^*)$ is invertible if and only if, for all $i \geq 1$, $i \in \mathbb{Z}$, the matrix $I - (1/(1 + \mu_i))\{ D^{-1} G_U(U^*) + I \}$ is nonsingular. Let $H(\mu) = H(U^*; \mu) = \det \{ \mu I - D^{-1} G_U(U^*) \}$
\[
= \frac{1}{d_1 d_2 d_3} \det \{ \mu D - G_U(U^*) \}. \tag{70}
\]

We can know that if $H(\mu) \neq 0$, the number of negative eigenvalues of $D_U F(U^*)$ on $X_{ij}$ is odd if and only if $H(\mu) < 0$ for every $1 \leq j \leq \dim E(\mu)$. According to this, we can form the following result.

**Proposition 8.** Assume that the matrix $\mu_i I - D^{-1} G_U(U^*)$ is nonsingular for all $i \geq 1$, then
\[
\text{index}(F(\cdot), U^*) = (-1)^\sigma,
\tag{71}
\]

where $\sigma = \sum_{i \geq 1, H(\mu_i) < 0} \dim E(\mu_i)$.

For calculating the sign of $H(\mu_i)$, we firstly consider the index of $(F(\cdot), U^*)$. The calculation shows that
\[
\det \{ \mu D - G_U(U^*) \} = \Phi_3(d_2) \mu^3 + \Phi_2(d_2) \mu^2 + \Phi_1(d_2) \mu - \det \{ G_U(U^*) \}
\equiv \Phi(d_2; \mu),
\tag{72}
\]

with
\[
\begin{align*}
\Phi_1(d_2) &= d_4 a_{11} a_{22} + d_4 a_{11} a_{33} + d_4 a_{12} a_{33} - d_4 a_{13} a_{21} - d_2 a_{13} a_{31}, \\
\Phi_2(d_2) &= -d_2 d_3 a_{11} + d_4 d_3 a_{22} + d_4 d_3 a_{33}, \\
\Phi_3(d_2) &= d_1 d_2 d_3,
\end{align*}
\tag{73}
\]

where $a_{ij}$ are shown as (21).

Consider the dependence of $\Phi$ on $d_2$. Let $\bar{\mu}_1(d_2)$, $\bar{\mu}_2(d_2)$, and $\bar{\mu}_3(d_2)$ be the three roots of $\Phi(d_2; \mu) = 0$, so that $\bar{\mu}_1(d_2) \bar{\mu}_2(d_2) \bar{\mu}_3(d_2) = \det \{ G_U(U^*) \}(\Phi_3(d_2))$. The computation leads to $\det \{ G_U(U^*) \} < 0$. Therefore, one of $\bar{\mu}_1(d_2)$, $\bar{\mu}_2(d_2)$, $\bar{\mu}_3(d_2)$ is real and negative, and the product of the other two is positive.

Considering the following limits:
\[
\begin{align*}
\lim_{d_2 \to -\infty} \Phi_1(d_2) &= d_4 d_3 a_{11}, \\
\lim_{d_2 \to -\infty} \Phi_2(d_2) &= -d_2 d_3 a_{11} + d_4 d_3 a_{22} + d_4 d_3 a_{33}, \\
\lim_{d_2 \to -\infty} \Phi_3(d_2) &= \mu [d_4 d_3 \mu^2 - (d_4 a_{33} + d_4 a_{11}) \mu + a_{11} a_{33} - a_{13} a_{31}].
\end{align*}
\tag{74}
\]

We establish the following result.

**Proposition 9.** Assume the parameters satisfy (7) or (8) and satisfy $2u^* - \alpha + (a_1 + 1)(b - \alpha, u^*) + \beta_2 c B^2 (\beta_2 + u^*) + c < 0$. If $a_{11} a_{33} - a_{13} a_{31} < 0$, there is a positive constant $D_2$, such that when $d_2 \geq D_2$, the three roots $\bar{\mu}_1(d_2)$, $\bar{\mu}_2(d_2)$, $\bar{\mu}_3(d_2)$ of $\Phi(d_2; \mu) = 0$ are all real and satisfy
\[
\begin{align*}
\lim_{d_2 \to -\infty} \bar{\mu}_1(d_2) &= \frac{(d_4 a_{33} + d_4 a_{11}) - \sqrt{(d_4 a_{33} + d_4 a_{11})^2 + 4 d_4 d_3 (a_{11} a_{33} - a_{13} a_{31})}}{2 d_4 d_3} < 0, \\
\lim_{d_2 \to -\infty} \bar{\mu}_2(d_2) &= 0, \\
\lim_{d_2 \to -\infty} \bar{\mu}_3(d_2) &= \frac{(d_4 a_{33} + d_4 a_{11}) + \sqrt{(d_4 a_{33} + d_4 a_{11})^2 + 4 d_4 d_3 (a_{11} a_{33} - a_{13} a_{31})}}{2 d_4 d_3} \equiv \bar{\mu} > 0.
\end{align*}
\tag{75}
\]
$-\infty < \tilde{\mu}_1(d_2) < 0 < \tilde{\mu}_2(d_2) < \tilde{\mu}_3(d_2).$  \hspace{1cm} (76)

$\Phi(d_2; \mu) < 0, \mu \in (-\infty, \tilde{\mu}_1(d_2)) \cup (\tilde{\mu}_2(d_2), \tilde{\mu}_3(d_2)).$  \hspace{1cm} (77)

$\Phi(d_2; \mu) > 0, \mu \in (\tilde{\mu}_1(d_2), \tilde{\mu}_2(d_2)) \cup (\tilde{\mu}_3(d_2), +\infty).$  \hspace{1cm} (78)

Now, we prove the existence of nonconstant positive solutions of (37) when $d_2$ is sufficiently large.

**Theorem 10.** Let the parameters $d_1, d_2$ are fixed, $\Gamma$ satisfies (7) or (8), and satisfies $2u^* - a + (a_1 + 1)(b - a_2u^*) + \beta_1 c B^2 (\beta_2 + u^*) + c < 0.$ If $a_{12}a_{13} - a_{11}a_{23} < 0,$ $\mu \in (\mu_n, \mu_{n+1})$ for some $n \geq 1,$ and the sum $\sigma_n = \sum_{i=1}^{n} \dim E(\mu_i)$ is odd. Then, $D_2$ must be as a positive constant such that (37) has one nonconstant positive solution at least if $d_2 \geq D_2.$

**Proof.** There exists a positive constant $D_2$ by Proposition 9, such that for $d_2 \geq D_2,$ (76), (77), and (78) hold and

$$0 = \mu_0 < \tilde{\mu}_2(d_2) < \mu_1, \tilde{\mu}_3(d_2) \in (\mu_n, \mu_{n+1}).$$  \hspace{1cm} (79)

We will testify that for any $d_2 \geq D_2,$ system (37) has at least one nonconstant positive solution and the proof is proved by contradiction. Assume on the contrary that the statement is not true for some $d_2 \geq D_2.$ Afterwards, we fix $d_2 = \tilde{d}_2,$ $d_1^* = C^1_1/\mu_{11},$ $d_2^* = C^2_1/\mu_{12},$ $d_3^* = C^3_1/\mu_{13},$ and

$$\tilde{d}_1 \geq \max \{d_1^*, d_1\},$$

$$\tilde{d}_2 \geq d_2^*,$$

$$\tilde{d}_3 \geq \max \{d_3^*, d_3\}.$$  \hspace{1cm} (80)

As for $t \in [0, 1],$ make $D(t) = \text{diag}(d_1(t), d_2(t), d_3(t))$ with $d_1(t) = td_1 + (1 - t)d_1, i = 1, 2, 3$ and think about the problem

$$\begin{align*}
-D(t) \Delta U &= G(t), \quad x \in \Omega, \\
\frac{\partial U}{\partial n} &= 0, \quad x \in \partial \Omega.
\end{align*}$$  \hspace{1cm} (81)

$U$ is a nonconstant positive solution of (37) if and only if it is a positive solution of (81) when $t = 1.$ Obviously for any $0 \leq t \leq 1,$ $U^*$ is the unique constant positive solution of (81). $U$ is a positive solution of (81) if and only

$$\text{F}(t; U) \equiv U - (I - \Delta)^{-1} \{D^{-1}(t)G(U) + U\} = 0, \quad U \in X^+. $$  \hspace{1cm} (82)

It is evident that $\text{F}(1; U) = \text{F}(U), \text{F}(0; U) = 0$ has been shown in Theorem 7, which has only positive solution $U^*$ in $X^*.$ After computing, we get that

$$D_U \text{F}(t; U^*) = I - (I - \Delta)^{-1} \{D^{-1}(t)G_U(U^*) + I\}. $$  \hspace{1cm} (83)

Specifically,

$$D_U \text{F}(0; U^*) = I - (I - \Delta)^{-1} \{D^{-1} G_U(U^*) + I\},$$

$$D_U \text{F}(1; U^*) = I - (I - \Delta)^{-1} \{D^{-1} G_U(U^*) + I\} = D_2 \text{F}(U^*),$$  \hspace{1cm} (84)

where $D = \text{diag}(\tilde{d}_1, \tilde{d}_2, \tilde{d}_3).$ From (70) and (72), we know that

$$H(\mu) = \frac{1}{d_1 d_2 d_3} \Phi(d_2; \mu).$$  \hspace{1cm} (85)

In view of (76) - (79), and (85), it follows that

$$H(\mu_{\ast}) > 0, \quad H(\mu_i) < 0, \quad 1 \leq i \leq n;$$

$$H(\mu_i) > 0, \quad i \geq n + 1.$$  \hspace{1cm} (86)

Thus, 0 is not an eigenvalue of the matrix $\mu_0 I - D^{-1} G_U(U^*)$ for any $i \geq 1,$ and

$$\sum_{i \geq 0, H(\mu_i) < 0} \dim E(\mu_i) = \sum_{i = 1}^{n} \dim E(\mu_i),$$  \hspace{1cm} (87)

which is odd. Because of Proposition 8, it can be true that

$$\text{index}(\text{F}(1; \cdot), U^*) = (-1)^\ast = -1.$$  \hspace{1cm} (88)

The same method is available to index $((\text{F}(0; \cdot), U^*)) = (-1)^0 = 1.$

According to Theorems 5 and 6, we can find a positive constant $C,$ such that the positive solutions of (81) can meet the demand $C^{-1} < u, v, w < C$ for all $0 \leq t \leq 1.$ So, $F(t; U) \neq 0$ on $\partial \Omega.$ By using the homotopy invariance of the topological degree, it is clear that

$$\text{deg}(\text{F}(1; \cdot), 0, B(C)) = \text{deg}(\text{F}(0; \cdot), 0, B(C)).$$  \hspace{1cm} (89)

Moreover, by our assumption, both equations $F(1; \cdot) = 0$ and $F(0; \cdot) = 0$ have only the positive solution $U^*$ in $B(C),$ so

$$\text{deg}(\text{F}(0; \cdot), 0, B(C)) = \text{index}(\text{F}(0; \cdot), U^*) = 1,$$

$$\text{deg}(\text{F}(1; \cdot), 0, B(C)) = \text{index}(\text{F}(1; \cdot), U^*) = -1,$$  \hspace{1cm} (90)

which is contradictory with (89).

The proof is complete.
