Abstract

For a given graph $G$, the metric and edge metric dimensions of $G$, $\dim(G)$ and $\edim(G)$, are the cardinalities of the smallest possible subsets of vertices in $V(G)$ such that they uniquely identify the vertices and the edges of $G$, respectively, by means of distances. It is already known that metric and edge metric dimensions are not in general comparable. Infinite families of graphs with pendant vertices in which the edge metric dimension is smaller than the metric dimension are already known. In this article, we construct a 2-connected graph $G$ such that $\dim(G) = a$ and $\edim(G) = b$ for every pair of integers $a, b$, where $4 \leq b < a$. For this we use subdivisions of complete graphs, whose metric dimension is in some cases smaller than the edge metric dimension. Along the way, we present an upper bound for the metric and edge metric dimensions of subdivision graphs under some special conditions.

Keywords: Edge metric dimension; metric dimension; 2-connected graphs; edge subdivision.

AMS Subject Classification numbers: 05C12; 05C76

1 Introduction

The definition of edge metric dimension of graphs appeared first in\cite{4} motivated by the problem of uniquely locating the connection between two vertices of a graph, that is the edge; and in addition, to giving more insight into the classical metric dimension.

knor@math.sk, skrekovski@gmail.com, ismael.gonzalez@uca.es
Given a connected graph $G$, a vertex $v \in V(G)$ and an edge $e = xy \in E(G)$, the distance between $e$ and $v$ is $d_G(e, v) = \min \{d_G(x, v), d_G(y, v)\}$, where $d_G(x, v)$ stands for the standard vertex distance in graphs, i.e., the length of a shortest $x$-$v$ path. A set of vertices $S \subset V(G)$ is an edge metric generator for $G$ if for any pair of distinct edges $e, f \in E(G)$, there exists a vertex $v \in S$ such that $d_G(e, v) \neq d_G(f, v)$. The cardinality of the smallest possible edge metric generator for $G$ is the edge metric dimension of $G$, denoted by $edim(G)$. An edge metric generator of cardinality $edim(G)$ is an edge metric basis of $G$. Any edge metric generator uniquely identifies (resolves or recognizes) all the edges of the graph. Concepts of metric generators, metric basis and metric dimension have analogous definitions, if we want to uniquely recognize the vertices of a graph instead of the edges. These three latter concepts were firstly and independently defined in [3] and [7]. The metric dimension of a graph $G$ is denoted by $dim(G)$. Recent results concerning edge metric dimension of graphs can be found in [1, 2, 6, 8, 9].

Relationships between the metric dimension and the edge metric dimension of graphs have become attracting for some researchers from the moment in which the seminal article [4] on edge metric dimension appeared. One reason for this attraction is based on the not clear comparability of such parameters. That is, the classical metric dimension can be smaller, equal or larger than the edge metric dimension as first proved in [4]. Several different infinite families of graphs having metric dimension smaller or equal than the edge metric dimension were already known from [4], and in contrast, only one infinite family (the torus graphs $C_4\square C_4$) with metric dimension larger than the edge metric dimension was known till recently. Moreover, for this family the difference between the metric and edge metric dimensions is just 1. Thus, a natural question raised up in [4] was regarding finding some other families of graphs $G$ satisfying that $edim(G) < dim(G)$. From [9], it was also known that the edge metric dimension cannot be bounded from above by a factor of the metric dimension, and thus, a similar question was there stated for the opposite direction.

The problem of finding some other families of graphs having edge metric dimension smaller than the metric dimension remained open till recently, when it was shown in [5], that for every $a$ and $b$, where $2 \leq b < a$, there is a graph $G$ such that $dim(G) = a$ and $edim(G) = b$. Hence, the metric dimension cannot be bounded from above by a factor of the edge metric dimension as well, giving answer to problems described in [4] and [9]. Notwithstanding, the graphs used in [5] have pendant vertices, which is not happening for the already known torus graphs from [4]. Thus, one may consider the question of finding families of graphs $G$ for which $edim(G) < dim(G)$, and having no vertices of degree one. Even more general, one would wonder if there is a relationship between constructing such kind of families of graphs regarding the $k$-connectedness, for $k \geq 2$, of the graphs of such families. In this work we center our attention in the case of 2-connected graphs (graphs without cut vertices), also known as block graphs, and we prove the following statement, which is the main result of this work.

**Theorem 1.** Let $a$ and $b$ be integers, such that $4 \leq b < a$. Then, there exists a 2-connected graph $G$ such that $dim(G) = a$ and $edim(G) = b$.

It remains unsolved if there is an analogue of Theorem 1 when $b = 2$ or $b = 3$. So, we
point out the following open problem. Note that a very particular case $b = 2$ and $a = 3$ follows by Lemma 7.

**Problem 1.** Are there graphs $G$ with $\text{edim}(G) = b$ and $\text{dim}(G) = a$ for each $b \in \{2, 3\}$ and $a > b$?

Observe that the torus graphs are 3-connected. In this sense, if there exist 3-connected graphs $G$ with $\text{edim}(G) = 6$ and $\text{dim}(G) = 7$, in which some edge metric basis is a subset of a metric basis, then by using the technique presented in this paper, and in [5], there may be a chance to construct other 3-connected graphs satisfying similar conclusions as in Theorem 1 (probably with a little bit worse lower bound on $b$), for this particular case. Unfortunately, at the moment the only known 3-connected graphs whose edge metric dimension is smaller than the metric dimension are the above mentioned torus graphs, for which $\text{dim}(G) = 4$ and $\text{edim}(G) = 3$. In consequence, we next state the following problem.

**Problem 2.** Let $b \geq 6$. Are there 3-connected graphs $G_b$ such that $\text{dim}(G_b) = b + 1$ and $\text{edim}(G_b) = b$ which have an edge metric basis which is a subset of some metric basis?

And more generally:

**Problem 3.** For which $k$ there exist $k$-connected graphs $G$ with $\text{dim}(G) > \text{edim}(G)$?

In the next section, we present several results that are then used to prove Theorem 1.

## 2 Metric and edge dimensions of subdivision graphs

The smallest value of $n$, $n \geq 3$, for which there exist graphs of order $n$ with edge metric dimension smaller than the metric dimension, is $n = 10$, see [3]. From [3, Figure 1], we observe that there is just one 2-connected graph with such order, which is indeed a subdivision of $K_4$. In this sense, we consider the class of subdivision graphs, since it seems that they could be good candidates for graphs which have edge metric dimension strictly smaller than the metric dimension.

Given a graph $G$, by *subdividing* one edge $uv$, we mean removing the edge $uv$, and adding an extra vertex $w$ and the edges $uw$ and $wv$. A *subdivision graph* is obtained from a graph $G$ by subdividing all its edges, and is denoted by $S(G)$. Note that, if $G$ has $n$ vertices and $m$ edges, then $S(G)$ is a bipartite graph with $n + m$ vertices and $2m$ edges. In order to prove Theorem 1 we first need the following results, which are bounds for the metric and edge metric dimensions of subdivision graphs, under some restrictions for the original not subdivided graphs. The bounds themselves are of interest based on the fact that tight useful bounds for the metric and edge metric dimensions of graphs are not commonly existing.

**Theorem 2.** Let $G$ be a graph on $n$ vertices. If $G$ contains $\left\lceil \frac{n}{3} \right\rceil$ vertex-disjoint paths of length 2, then $\text{dim}(S(G)) \leq \left\lfloor \frac{2n}{3} \right\rfloor$. 
Proof. We construct a set $T$ of the required cardinality and show that such $T$ is a metric generator for $S(G)$. Denote the vertices of $G$ by $v_1, v_2, \ldots, v_n$, so that the $\left\lfloor \frac{n}{3} \right\rfloor$ vertex-disjoint paths of length 2 are $v_1v_2v_3, v_4v_5v_6, \ldots, v_{\alpha-2}v_{\alpha-1}v_{\alpha}$, where $\alpha = 3\left\lceil \frac{n}{3} \right\rceil$. Further, if $v_iv_j \in E(G)$, then denote by $x_{ij}$ the vertex of degree 2 connected to $v_i$ and $v_j$ in $S(G)$. Let $T' = \{x_{1,2}, x_{2,3}, x_{4,5}, x_{5,6}, \ldots, x_{\alpha-2,\alpha-1}, x_{\alpha-1,\alpha}\}$. Now, let $T = T'$ if $n \equiv 0 \pmod{3}$, $T = T' \cup \{v_n\}$ if $n \equiv 1 \pmod{3}$, and $T = T' \cup \{v_{n-1}, v_n\}$ if $n \equiv 2 \pmod{3}$. Obviously, $|T| = \left\lceil \frac{2n}{3} \right\rceil$. So, it remains to show that $T$ is a metric generator for $S(G)$.

Consider the vertex $x_{1,2}$ of $T$. This vertex partitions the set of vertices of $S(G)$ into several sets according to their distance from $x_{1,2}$. Clearly, $x_{1,2}$ distinguishes any two vertices belonging to two different such sets. Thus, it suffices to examine pairs of vertices, say $y$ and $z$, belonging to a common set. Since there is only one vertex at distance 0 from $x_{1,2}$, we consider the sets of vertices at distance 1 and 2 from $x_{1,2}$. As will be shown below, it is not necessary to consider sets of vertices at larger distance from $x_{1,2}$.

Case 1: $d(x_{1,2}, y) = d(x_{1,2}, z) = 1$. Then $y = v_1$ and $z = v_2$. We have $d(x_{2,3}, v_1) = 3$ and $d(x_{2,3}, v_2) = 1$, and so $y, z$ are identified by $x_{2,3}$.

Case 2: $d(x_{1,2}, y) = d(x_{1,2}, z) = 2$. We may assume that $y, z \neq x_{2,3}$, otherwise $x_{2,3}$ distinguishes $y$ and $z$. If $y = x_{1,j}$ and $z = x_{2,k}$, then $d(x_{2,3}, z) = 2$ while $d(x_{2,3}, y) \geq 2$ and the equality is attained only if $j = 3$. But, in that case $v_k$ is at distance at most 1 from a vertex of $T$ and this vertex distinguishes $y$ and $z$. So, we may consider the case when $y = x_{2,j}$ and $z = x_{2,k}$, where $j < k$. The case when $y = x_{1,j}$ and $z = x_{1,k}$ can be solved analogously. We also assume that $j, k \neq 3$, otherwise $x_{2,3}$ distinguishes $y$ and $z$. If $v_k \in T$, then this vertex distinguishes $y$ and $z$. Thus, it remains to consider the case when $v_j$ and $v_k$ are at distance 1 from vertices of $T'$. But then there is such a vertex of $T'$ which is at distance 1 from one of $v_j, v_k$ and at distance at least 3 from the other. And this vertex distinguishes $y$ and $z$. This establishes the case.

Using analogous arguments for the remaining vertices of $T'$, we see that the only vertices of $S(G)$ which may not be distinguished by $T$ are at distance at least 3 from every vertex of $T'$. However, there is not such a vertex if $n \equiv 0 \pmod{3}$. If $n \equiv 1 \pmod{3}$, then there is just one such vertex, namely $v_n$. Finally, if $n \equiv 2 \pmod{3}$ it remains to consider three vertices (or two if $v_{n-1}v_n \notin E(G)$), namely $v_{n-1}, x_{n-1,n}$ and $v_n$. But these vertices are distinguished by either of $v_{n-1}$ and $v_n$. And since $v_{n-1}, v_n \in T$, the set $T$ is a metric generator for $S(G)$ also in this case. This concludes the proof.

We next present an analogous result of the previous one, for the edge metric dimension.

Theorem 3. Let $G$ be a graph on $n$ vertices. If $G$ contains $\left\lfloor \frac{n-1}{3} \right\rfloor$ vertex-disjoint paths of length 2, then $\text{edim}(S(G)) \leq \left\lfloor \frac{2n-2}{3} \right\rfloor$.

Proof. Analogously as in the proof of Theorem 2 we construct a set $T$ of the required size, and show that $T$ is an edge metric generator for $S(G)$. As in Theorem 2 we use a similar notation for the vertices of $G$, $S(G)$, and the set $T'$, but now considering $\alpha = 3\left\lceil \frac{n-1}{3} \right\rceil$, but now considering $\alpha = 3\left\lceil \frac{n-1}{3} \right\rceil$. 

4
that is $T' = \{x_{1,2}, x_{2,3}, x_{4,5}, x_{5,6}, \ldots, x_{\alpha-2,\alpha-1}, x_{\alpha-1,\alpha}\}$. Now, let $T = T'$ if $n \equiv 1 \pmod{3}$; $T = T' \cup \{v_{n-1}\}$ if $n \equiv 2 \pmod{3}$; and $T = T' \cup \{v_{n-2}, v_{n-1}\}$ if $n \equiv 0 \pmod{3}$. Then $v_n$ is not in $T$ and it is not adjacent to a vertex of $T$. Obviously, $|T| = \lceil \frac{2n-1}{3} \rceil$. It remains to show that $T$ is a metric generator for $S(G)$.

Consider the vertex $x_{1,2}$ of $T$. This vertex partitions the set of edges of $S(G)$ into several sets according to their distance from $v_{1,2}$. Obviously, $x_{1,2}$ distinguishes edges belonging to different sets. Thus, we examine pairs of edges, say $e$ and $f$, belonging to a common set. It suffices to consider the following three cases.

**Case 1:** $d(x_{1,2}, e) = d(x_{1,2}, f) = 0$. Hence, $e = v_1x_{1,2}$ and $f = v_2x_{1,2}$. We have $d(x_{2,3}, e) = 2$ and $d(x_{2,3}, f) = 1$, and so $x_{2,3}$ distinguishes $e, f$.

**Case 2:** $d(x_{1,2}, e) = d(x_{1,2}, f) = 1$. If $e = v_1x_{1,j}$ and $f = v_2x_{2,k}$, then $d(x_{2,3}, f) = 1$ and $d(x_{2,3}, e) \geq 2$, and so, again $x_{2,3}$ distinguishes $e, f$. Assume that $e = v_2x_{2,j}$ and that $f = v_2x_{2,k}$, where $j < k$. The case when both $e$ and $f$ are incident to $v_1$ is analogous. We may assume that $j, k \neq 3$, otherwise $x_{2,3}$ distinguishes $e$ and $f$. If $k = n$, then there is a vertex $z \in T$ which is at distance at most 1 from $v_j$ and this vertex distinguishes $e$ and $f$. If $v_k \in T$, then $v_k$ distinguishes $e$ and $f$. Thus, it remains to consider the case when $v_j$ and $v_k$ are at distance 1 from vertices of $T'$. But then there is a vertex in $T'$ which is at distance 1 from one of $v_j, v_k$ and at distance at least 3 from the other. And this vertex distinguishes $e$ and $f$.

**Case 3:** $d(x_{1,2}, e) = d(x_{1,2}, f) = 2$. This case can be solved analogously as the previous one, so we omit the discussion.

Using analogous arguments for the remaining vertices of $T'$, we see that the only edges of $S(G)$ which may not be distinguished by $T$ are at distance at least 3 from every vertex of $T'$. However, there is not such an edge if $n \equiv 1 \pmod{3}$. If $n \equiv 2 \pmod{3}$, then the edges are $v_{n-1}x_{n-1,n}$ and $v_nx_{n-1,n}$ (if $v_{n-1}v_n \in E(G)$), and since $v_{n-1} \in T$, these edges are distinguished by $T$. Finally, if $n \equiv 0 \pmod{3}$, then there are at most three edges connecting pairs of vertices of $\{v_{n-2}, v_{n-1}, v_n\}$ in $G$. If all the three edges $v_n-v_{n-1}, v_n-v_n$ and $v_{n-1}v_n$ are in $G$, then it remains to consider six edges of the 6-cycle $C = v_{n-2}x_{n-2,n-1}v_{n-1}x_{n-1,n}v_nv_{n-2,n}$ in $S(G)$. Since $v_{n-2}, v_{n-1} \in T$ and these two vertices form an edge metric basis for $C$, the set $T$ is an edge metric generator for $S(G)$. The other cases (when 0, 1 or 2 edges of $v_{n-2}v_{n-1}, v_{n-2}v_n, v_{n-1}v_n$ are in $G$) are even simpler.

The bounds in Theorems 2 and 3 can be violated if $G$ does not contain a required number of vertex-disjoint paths. For instance, the complete bipartite graph $K_{n,1,1}$ has $n$ vertices and there are not two vertex-disjoint paths of length 2 in $K_{n,1,1}$. It is easy to see that $\text{dim}(S(K_{n,1,1})) = \text{edim}(S(K_{n,1,1})) = n - 2 > \lceil \frac{2n-1}{3} \rceil$ if $n \geq 9$.

### 2.1 Subdivisions of complete graphs minus a matching

In the next we show that there are graphs of order $n$ for which the bounds in Theorems 2 and 3 are sharp. If $n \equiv 0 \pmod{3}$, then these graphs have edge metric dimension smaller
such that $uw, vw$ these vertices by
adjacent to vertices of degree 2 in
distance 2 in $S$
edges and at most $G$
put to
$n$
some of the vertices of degree at least $S$
the two neighbors of $s$
edim($S$)
as above.
vertex of degree 2 adjacent to
$v$
q
case
Suppose that $deg_G(v)$, in $G$ is at least $n - 2$, then we put the vertex $v$ to $H$. If $x \in S$ and $deg_G(x) = 2$, then we put to $H$ the two neighbors of $x$, together with the edge joining them. Hence, if $S$ contains $s_1$ vertices of degree at least $n - 2$ and $s_2$ vertices of degree 2, then $H$ contains exactly $s_2$ edges and at most $s_1 + 2s_2$ vertices, since some vertices of degree at least $n - 2$ in $S$ can be adjacent to vertices of degree 2 in $S$ and some pairs of vertices of degree 2 in $S$ can have distance 2 in $G$. We prove two claims about $H$.

Claim 1. $H$ contains at least $n - 1$ vertices.

Suppose that there are 2 vertices of degree at least $n - 2$ in $G$, which are not in $H$. Denote these vertices by $u$ and $v$. By the assumption on $n$ in the statement, there is $w \in V(K^k_n)$ such that $uw, vw \in E(K^k_n)$. Let $y$ (resp. $z$) be the vertex of degree 2 adjacent to both $w$ and $u$ (resp. $v$). Denote $e = yw$ and $f = zw$.

If $s \in S$ and $deg_G(s) = 2$, then either $s$ is adjacent to $w$, in which case $d_G(s, e) = d_G(s, f) = 1$; or $s$ is not adjacent to $w$, in which case $d_G(s, e) = d_G(s, f) = 3$, since one of the two neighbors of $s$ is connected to $w$ by an edge in $K^k_n$ and $s$ is adjacent to neither of $u$ and $v$. On the other hand, if $s \in S$ and $deg_G(s) \geq n - 2$, then either $sw \in E(K^k_n)$, in which case $d_G(s, e) = d_G(z, f) = 2$; or $sw \notin E(K^k_n)$, in which case $d_G(s, e) = d_G(z, f) = 3$, since $su, sv \in E(K^k_n)$. Consequently, $e, f$ are not distinguished by $S$, a contradiction. This proves the claim.

Claim 2. If $uv \in E(H)$, then either $S$ contains one of $u$ and $v$, or there is another edge adjacent to $uv$ in $H$.

Suppose that $deg_G(q) = 2$ and $q \in S$. Let $u$ and $v$ be the vertices of degree at least $n - 2$ adjacent to $q$. Moreover, suppose that $S$ does not contain $u, v$ and $S$ does not contain a vertex of degree 2 adjacent to $u$ or $v$ other than $q$. By the assumption on $n$ in the statement, there is $w \in V(K^k_n)$ such that $uw, vw \in E(K^k_n)$. Let $y$ (resp. $z$) be the vertex of degree 2 adjacent to both $w$ and $u$ (resp. $v$). Denote $e = yw$ and $f = zw$. We proceed analogously as above.

If $s \in S \setminus \{q\}$ and $deg_G(s) = 2$, then either $s$ is adjacent to $w$, in which case $d_G(s, e) = d_G(s, f) = 1$; or $s$ is not adjacent to $w$, in which case $d_G(s, e) = d_G(s, f) = 3$, since one of the two neighbors of $s$ is connected to $w$ by an edge in $K^k_n$, and $s$ is neither adjacent to $u$ nor to $v$. On the other hand, if $s \in S$ and $deg_G(s) \geq n - 2$, then either $sw \in E(K^k_n)$, in which case $d_G(s, e) = d_G(s, f) = 2$; or $sw \notin E(K^k_n)$, in which case $d_G(s, e) = d_G(s, f) = 3$,
since $su, sv \in E(K^k_n)$. Since $d_G(q,e) = d_G(q,f) = 2$, we obtain that $e, f$ are not identified by $S$, which is a contradiction. This establishes the claim.

Now, let $C$ be a connected component of $H$. If $C$ has only one vertex, then $C$ was created by using one vertex of degree at least $n - 2$ in $S$. If $C$ has two vertices, then it was created by using one vertex of degree 2 in $S$, and at least one vertex of degree at least $n - 2$ in $S$, by Claim 2. If $C$ has $t$ vertices, $t \geq 3$, then $C$ was created using at least $t - 1$ vertices of degree 2 in $S$ and maybe some vertices of degree at least $n - 2$ in $S$. By Claim 1, $H$ contains at least $n - 1$ vertices, and so $S$ contains at least $2 \left\lceil \frac{n-1}{3} \right\rceil + c$ vertices. Here $c = 0$ if $n \equiv 1 \pmod{3}$, $c = 1$ if $n \equiv 2 \pmod{3}$ and $c = 2$ if $n \equiv 0 \pmod{3}$. Hence $2 \left\lceil \frac{n-1}{3} \right\rceil + c = \left\lceil \frac{2n-2}{3} \right\rceil$, and so $|S| \geq \left\lceil \frac{2n-2}{3} \right\rceil$.

To prove that $\dim(G) \leq \left\lceil \frac{n-2}{3} \right\rceil$ it suffices to show that there are $\left\lceil \frac{n-2}{3} \right\rceil$ vertex disjoint paths of length 2 in $G$, by Theorem 3. But this is a consequence of the fact that $K^k_n$ has a Hamiltonian cycle (by using the Dirac theorem).

We next consider $\dim(G)$, so let $S$ be a metric generator for $G$. Let $H$ be an auxiliary graph constructed as above. We prove three claims about $H$ as before, where the first two are similar as before.

Claim 3. $H$ contains at least $n - 1$ vertices.

Suppose that there are 2 vertices $u$ and $v$ of degree at least $n - 2$ in $G$, which are not in $H$. By the assumption on $n$ in the statement, there is $w \in V(K^k_n)$ such that $uw, vw \in E(K^k_n)$. Let $y$ (resp. $z$) be the vertex of degree 2 adjacent to both $w$ and $u$ (resp. $v$).

If $s \in S$ and $\deg_G(s) = 2$, then either $s$ is adjacent to $w$, in which case $d_G(s, y) = d_G(s, z) = 2$; or $s$ is not adjacent to $w$, in which case $d_G(s, y) = d_G(s, z) = 4$, since one of the two neighbors of $s$ is connected to $w$ by an edge in $K^k_n$ and $s$ is adjacent to neither of $u$ and $v$. On the other hand, if $s \in S$ and $\deg_G(s) \geq n - 2$, then either $sw \in E(K^k_n)$, in which case $d_G(s, y) = d_G(s, z) = 3$; or $sw \notin E(K^k_n)$, in which case $d_G(s, y) = d_G(s, z) = 3$, since $su, sv \in E(K^k_n)$. Consequently, $y, z$ are not identified by $S$, a contradiction. This proves the claim.

Claim 4. If $uw \in E(H)$, then either $S$ contains one of $u$ and $v$, or there is another edge adjacent to $uv$ in $H$.

Suppose that $\deg_G(q) = 2$ and that $q \in S$. Let $u$ and $v$ be the vertices of degree at least $n - 2$ adjacent to $q$. Moreover, suppose that $S$ does not contain $u, v$ and $S$ does not contain a vertex of degree 2 adjacent to $u$ or $v$ other than $q$. By the assumption on $n$ in the statement, there is $w \in V(K^k_n)$ such that $uw, vw \in E(K^k_n)$. Let $y$ (resp. $z$) be the vertex of degree 2 adjacent to both $w$ and $u$ (resp. $v$). We proceed analogously as above.

If $s \in S \setminus \{q\}$ and $\deg_G(s) = 2$, then either $s$ is adjacent to $w$, in which case $d_G(s, y) = d_G(s, z) = 2$; or $s$ is not adjacent to $w$, in which case $d_G(s, y) = d_G(s, z) = 4$, since one of the two neighbors of $s$ is connected to $w$ by an edge in $K^k_n$ and $s$ is neither adjacent to $u$ nor to $v$. On the other hand, if $s \in S$ and $\deg_G(s) \geq n - 2$, then either $sw \in E(K^k_n)$, in which case $d_G(s, y) = d_G(s, z) = 3$; or $sw \notin E(K^k_n)$, in which case $d_G(s, y) = d_G(s, z) = 3$, since
and consequently with
\( su, sv \in E(K_n^k) \). Since \( d_G(q, y) = d_G(q, z) = 2 \), we have that \( y, z \) are not distinguished by \( S \), a contradiction. This proves the claim.

**Claim 5.** If there is a vertex of \( K_n^k \) which is not in \( H \), then \( H \) can contain at most \( k \) components with exactly two edges whose end vertices are not in \( S \).

Suppose that there is a vertex of \( K_n^k \), say \( r \), which is not in \( H \). Let \( C \) be a connected component of \( H \) containing exactly 2 edges and let \( V(C) \cap S = \emptyset \). Denote the edges of \( C \) by \( uv \) and \( vw \).

Suppose first that \( uw, vr \in E(K_n^k) \). Denote by \( y \) the vertex of degree 2 adjacent to \( u \) and \( w \), and denote by \( z \) the vertex of degree 2 adjacent to \( v \) and \( r \) in \( G \). For any \( s \in S \), we consider two possibilities. First, if \( \deg_G(s) = 2 \), then either \( s \) is one of the two vertices which caused an edge of \( C \), in which case \( d_G(s, y) = d_G(s, z) = 2 \); or \( s \) is not adjacent to a vertex of \( \{u, v, w, r\} \), in which case \( d_G(s, y) = d_G(s, z) = 4 \), since one of the two neighbors of \( s \) is connected to \( r \) (and one of them is connected to \( u \)) by an edge in \( K_n^k \). Second, if \( s \in S \) and \( \deg_G(s) \geq n - 2 \), then \( sv \in E(K_n^k) \) or \( sr \in E(K_n^k) \), and also \( su \in E(K_n^k) \) or \( sw \in E(K_n^k) \), which implies \( d_G(s, y) = d_G(s, z) = 3 \). Thus, in both possibilities, we conclude that \( y, z \) are not identified by \( S \), a contradiction.

This means that at least one of the edges \( uw \) and \( vr \) must be missing in \( K_n^k \). Observe that, if \( H \) has another component \( C' \) on two edges, say \( u'v' \) and \( v'w' \), with \( V(C') \cap S = \emptyset \), then for the pairs \( u'w' \) and \( v'r \) we have \( \{u'w', v'r\} \cap \{uw, vr\} = \emptyset \). Since there are only \( k \) pairs of vertices which are not connected by an edge in \( K_n^k \), \( H \) can have at most \( k \) components with exactly two edges whose end vertices are not in \( S \). This proves Claim 5.

In consequence, there are two cases to consider. If \( |V(H)| = n - 1 \), then \( |S| \geq \beta = 2k + \lceil \frac{3n - 3k - 1}{4} \rceil \). On the other hand, if \( |V(H)| = n \), then \( |S| \geq \gamma = \lfloor \frac{2n}{3} \rfloor \). Observe that \( \gamma \leq \beta \) is equivalent with

\[
\left\lfloor \frac{2n}{3} \right\rfloor - 1 < \left\lfloor \frac{3n - k - 3}{4} \right\rfloor. \tag{1}
\]

Let \( n = 3t + \ell \), where \( \ell = n \mod 3 \). Then (1) is equivalent with

\[
2t + \ell - 1 < \frac{9t + 3\ell - k - 3}{4},
\]

and consequently with

\[
k + \ell - 1 < t.
\]

Thus, \( \gamma \leq \beta \) is equivalent with \( 3k + 4\ell - 3 < 3t + \ell = n \), and so with \( n \geq 3k + 4\ell - 2 \). By the assumption on \( n \) in the statement we get \( |S| \geq \lfloor \frac{2n}{3} \rfloor \).

To prove \( \dim(S(K_n^k)) \leq \left\lfloor \frac{2n}{3} \right\rfloor \) it suffices to show that there are \( \lfloor \frac{n}{3} \rfloor \) vertex disjoint paths of length 2 in \( K_n^k \), by Theorem 2. Analogously as above, this is a consequence of the fact that \( K_n^k \) has a Hamiltonian cycle. \( \square \)

Since \( 3k + 4\ell - 2 \leq 3k + 6 \), we have the following corollary of Theorem 4.
Corollary 5. Let $k \geq 1$ and let $n \geq 3k + 6$. Then $\dim(S(K^n_k)) = \dim(S(K^n_n))$ if $n \equiv 0 \pmod{3}$ and $\dim(S(K^n_k)) = \dim(S(K^n_n)) + 1$ otherwise.

And for $S(K_n)$ we have the following statement.

Proposition 6. Let $n \geq 4$. Then $\dim(S(K_n)) = \lfloor \frac{2n-2}{3} \rfloor$ and $\dim(S(K_n)) = \lfloor \frac{2n}{3} \rfloor$, with the unique exception when $\dim(S(K_5)) = 3$ instead of 4.

Proof. For $n \neq 5$ the statement is a direct consequence of Theorem 4. For $n = 5$ the only problem is that $4 = \gamma > \beta = 3$ in this case (see the proof of Theorem 4). Using the notation of Theorem 4 let $T = \{x_1, x_2, x_3, x_4\}$. Then the corresponding graph $H$ has 4 vertices and it is easy to check that $T$ is a metric generator for $S(K_5)$. □

By Proposition 6 we have $\dim(S(K_{3t+1})) = 2t$ and $\dim(S(K_{3t+1})) = 2t + 1$ for every $t \geq 1$, and also $\dim(S(K_{3t+2})) = 2t + 1$ and $\dim(S(K_{3t+2})) = 2t + 2$ for every $t \geq 2$. Hence, we have the following statement.

Lemma 7. For every $c_1 \geq 2$, $c_1 \neq 3$, there is an integer $q$ such that $\dim(S(K_q)) = c_1$ and $\dim(S(K_q)) = c_1 + 1$.

3 Proof of Theorem 1

Clearly, Lemma 7 shows that Theorem 1 is true for the case when $\dim(G) - \dim(G) = 1$. In the following we consider the case with a larger difference.

Let $c_1 \geq 4$ and $c_2 \geq c_1 + 2$ be two integers. We are aimed to construct a graph $G_{c_1,c_2}$ for which $\dim(G_{c_1,c_2}) = c_1$ and $\dim(G_{c_1,c_2}) = c_2$. Let $k = c_2 - c_1$ and observe that $k \geq 2$. We first take $k$ graphs $G_1, G_2, \ldots, G_k$ and connect them into a structure that resembles a path. The graphs $G_1, G_2, \ldots, G_{k-1}$ are isomorphic to $S(K_2)$, while $G_k$ is isomorphic to a graph $S(K_q)$, for some integer $q$, satisfying $\dim(S(K_q)) = c_1$. Since $c_1 \geq 4$, by Lemma 7 there always exists the required integer $q$.

Now we denote the vertices of degree at least 3 in $G_i$ by $v^i_1, v^i_2, \ldots, v^i_{\dim(G_i)}$, and we denote the vertex of degree 2 adjacent to $v^i_a$ and $v^i_b$ by $x^i_{a,b}$. By using this notation, we add to the disjoint union of $G_1, G_2, \ldots, G_k$ the edges $x^i_{1,2}x^{i+1}_{2,3}$ and $x^i_{4,5}x^{i+1}_{5,6}, 1 \leq i \leq k - 1$, see Figure 1 for a sketch of the construction.

In the proof of $\dim(G_{c_1,c_2}) = c_1$ and $\dim(G_{c_1,c_2}) = c_2$ we use the following lemma.

Lemma 8. Let $G$ be a graph with a subgraph $H$. Let $z_1, z_2, \ldots, z_t$ be vertices of $H$ that have neighbors in $V(G) \setminus V(H)$. If $\dim(H) = c$ (resp. $\dim(H) = c$), then every (resp. edge) metric generator for $G$ contains at least $c - t$ vertices of $V(H) \setminus \{z_1, z_2, \ldots, z_t\}$.

Proof. We present the proof for $\dim(G)$ only, since for $\dim(G)$ it is almost the same. Consider the equivalence classes of $V(H)$ formed by distances from $z_1, z_2, \ldots, z_t$. Two vertices, say $u_1$ and $u_2$, are in the same equivalence class if $d(u_1, z_i) = d(u_2, z_i)$ for every $i, 1 \leq i \leq t$.

Now take two vertices, say $y_1$ and $y_2$, from the same equivalence class, and take a vertex $z \in V(G) \setminus V(H)$. Denote $a_i = d(z, z_i)$ and $b_i = d(z, y_1)$ ($= d(z, y_2)$), $1 \leq i \leq t$. Then...
Observe that $G$ of $V$ for $3 + (G)$ vertices and edges which have influence on the construction have been drawn. Also, recall that $G_k$ might be different from the remaining $G_i$.

Proof. We start with the lower bound. Since $\dim(\bigcap_{i=1}^{c} V_i) = \min\{a_i + b_i; 1 \leq i \leq t\} = d(z, y_2)$, hence, no vertex outside $H$ can separate $y_1$ and $y_2$ by means of distances. Thus, even if all the vertices of $(V(G) \setminus V(H)) \cup \{z_1, z_2, \ldots, z_t\}$ are in a metric generator, they will not distinguish vertices of $H$ which are not distinguished by the set $\{z_1, z_2, \ldots, z_t\}$ alone. Consequently, since $\dim(H) = c$, to distinguish vertices of $H$ every metric generator for $G$ must have at least $c - t$ vertices of $V(H) \setminus \{z_1, z_2, \ldots, z_t\}$. \hfill $\Box$

Now we determine the metric and edge metric dimensions of $G_{c_1,c_2}$, which shall complete the proof of Theorem 1.

**Lemma 9.** For every pair of integers $c_1$ and $c_2$, such that $c_1 \geq 4$ and $c_2 \geq c_1 + 2$, we have $\text{edim}(G_{c_1,c_2}) = c_1$ and $\dim(G_{c_1,c_2}) = c_2$.

Proof. We start with the lower bound. Since $\dim(S(K_7)) = 5$ and $\dim(S(K_q)) = c_1 + 1$, every metric generator for $G_{c_1,c_2}$ must contain at least 3 vertices of $V(G_1) \setminus \{x_{1,2}^1, x_{4,5}^1\}$, at least 1 vertex of $V(G_1) \setminus \{x_{1,2}^2, x_{2,3}^2, x_{4,5}^2, x_{5,6}^2\}$, $2 \leq i \leq k - 1$, and at least $c_1 - 1$ vertices of $V(G_k) \setminus \{x_{2,3}^k, x_{5,6}^k\}$, by Lemma. Thus, every metric generator for $G_{c_1,c_2}$ must have at least $3 + (k-2) + (c_1-1) = c_2$ vertices, and so $\dim(G_{c_1,c_2}) \geq c_2$.

Analogously, since $\dim(S(K_7)) = 4$ and $\dim(S(K_q)) = c_1$, every edge metric generator for $G_{c_1,c_2}$ must contain at least 2 vertices of $V(G_1) \setminus \{x_{1,2}^1, x_{4,5}^1\}$ and at least $c_1 - 2$ vertices of $V(G_k) \setminus \{x_{2,3}^k, x_{5,6}^k\}$, by Lemma. Thus, $\text{edim}(G_{c_1,c_2}) \geq c_1$.

For the upper bound we use the bases defined in the proofs of Theorems 2 and 3. Observe that $G_i \cong S(K_r)$ where $r \geq 7$, so that all these bases contain $x_{1,2}^i, x_{2,3}^i, x_{4,5}^i, x_{5,6}^i$.
in $G_i$. We start with $\text{edim}(G_{c_1,c_2})$. Thus, we show that $T = \{x_{2,3}^1, x_{5,6}^1, x_{1,2}^k, x_{4,5}^k, \ldots \}$ is an edge metric basis in $G_{c_1,c_2}$ (observe that $T$ is composed by vertices only from $G^1$ and $G^k$). For this we show that the partition of edges of $G_1$ via distances from $x_{1,2}^1$ can be modelled by distances from $x_{1,2}^k$ and $x_{4,5}^k$. And, by symmetry we can have a similar statement for $x_{4,5}^k$. Indeed, let $d(x_{1,2}^k, x_{1,2}^1) = a$. In fact, $a = 3(k - 1)$. Then $d(x_{4,5}^k, x_{1,2}^1) = a + 2$. Thus, edges of $G_1$ at distance 0 from $x_{1,2}^1$ are those which are in $G_1$ (see below) and at distance $a$ from $x_{1,2}^k$. Edges of $G_1$ at distance 1 from $x_{1,2}^1$ are those which are in $G_1$ and at distance $a + 1$ from $x_{1,2}^k$. Finally (it suffices to consider edges at distance 0, 1 and 2 from $x_{1,2}^1$; see the proof of Theorem 3), edges of $G_1$ at distance 2 from $x_{1,2}^1$ are those which are in $G_1$, at distance $a + 2$ from $x_{1,2}^k$ and at distance greater than $a$ from $x_{4,5}^k$ (to avoid the two edges at distance 0 from $x_{4,5}^k$). Analogously, we can reconstruct the partition of $E(G_i)$ from any one of the vertices of $G_i$ which have a neighbour outside $G_i$, $1 \leq i \leq k$.

Hence, it remains to show how the distances from $x_{2,3}^1, x_{5,6}^1, x_{1,2}^k$ and $x_{4,5}^k$ can be used to detect edges of $G_i$ and how to identify the edges connecting $G_i$ with $G_{i+1}$, $1 \leq i \leq k - 1$. As regards the edges connecting $G_i$ with $G_{i+1}$, observe that $x_{1,2}^i x_{2,3}^{i+1}$ (resp. $x_{4,5}^i x_{5,6}^{i+1}$) is the unique edge at distance $2 + 3(i - 1)$ from $x_{2,3}^1$ (resp. $x_{5,6}^1$) and at distance $2 + 3(k - i - 1)$ from $x_{1,2}^k$ (resp. $x_{4,5}^k$). Finally, edges of $G_1$ are those which are at distance at most 3 from both $x_{2,3}^1$ and $x_{5,6}^1$; edges of $G_2$ are those which are not in $E(G_1) \cup \{x_{1,2}^1 x_{2,3}^2, x_{4,5}^2 x_{5,6}^1\}$ and at distance at most 6 from both $x_{2,3}^1$ and $x_{5,6}^1$; etc. Hence, $T$ distinguishes all edges of $G_{c_1,c_2}$. Since $|T| = c_1$, we have $\text{edim}(G_{c_1,c_2}) \leq c_1$.

The proof of $\text{dim}(G_{c_1,c_2}) \leq c_2$ is analogous.
