SIMULTANEOUS CONTROL OF WAVE SYSTEMS

JINGRUI NIU

Abstract. In this paper, we study the simultaneous controllability of wave systems with different speeds in an open domain of $\mathbb{R}^d$, $d \in \mathbb{N}^*$, and under a uniqueness assumption for eigenfunctions, we prove the exact controllability with a single control command. We then study this uniqueness assumption and both provide a counterexample (for which we hence only obtain a partial controllability result on a co-finite dimensional space) and examples to ensure the unique continuation property. For the case of constant coefficients and possibly multiple control functions, we prove the controllability property is equivalent to an appropriate Kalman rank condition.

1. INTRODUCTION

Let $\Omega \subset \mathbb{R}^d$, $d \in \mathbb{N}^*$, be a bounded, and smooth domain. For positive constants $\alpha$ and $\beta$, let $k_{ij}(x) : \Omega \rightarrow \mathbb{R}$, $1 \leq i, j \leq d$ be smooth functions which satisfy:

$$
(1.1) \quad k_{ij}(x) = k_{ji}(x), \alpha|\xi|^2 \leq \sum_{1 \leq i,j \leq d} k_{ij}(x)\xi_i\xi_j \leq \beta|\xi|^2, \forall x \in \Omega, \forall \xi \in \mathbb{R}^d.
$$

Define $K(x)$ to be the symmetric positive definite matrix of coefficients $k_{ij}(x)$. Moreover, we define the density function $\kappa(x) = \frac{1}{\sqrt{\det(K(x))}}$. We also define the Laplacian by $\Delta_K = \frac{1}{\kappa(x)} \text{div}((\kappa(x)K\nabla \cdot) \Omega$ and the d’Alembert operator $\Box_K = \partial_t^2 - \Delta_K$ on $\mathbb{R}_t \times \Omega$. We assume that $\omega$ is a nonempty open subset of $\Omega$. We consider the interior
simultaneous controllability problem for the following wave system:

\[
\begin{align*}
\Box K_i u_1 &= b_1 f 1_{[0,T]}(t) 1_\omega(x) \text{ in } [0,T] \times \Omega, \\
\Box K_i u_2 &= b_2 f 1_{[0,T]}(t) 1_\omega(x) \text{ in } [0,T] \times \Omega, \\
\vdots
\end{align*}
\]

(1.2)

\[
\begin{align*}
\Box K_i u_n &= b_n f 1_{[0,T]}(t) 1_\omega(x) \text{ in } [0,T] \times \Omega, \\
u_j &= 0 \quad \text{on } [0,T] \times \partial \Omega, 1 \leq j \leq n, \\
u_j(0,x) &= u_j^0(x), \quad \partial_t u_j(0,x) = u_j^1(x), 1 \leq j \leq n.
\end{align*}
\]

(1.3)

Here, we choose \(K_i(1 \leq i \leq n)\) to be \(n\) different symmetric positive definite matrices. The state of the system is \((u_1, \partial_t u_1, \cdots, u_n, \partial_t u_n)\) and \(f\) is our control function. \(b_i\) are \(n\) nonzero constant coefficients. In this paper, we mainly consider the exact controllability for the system (1.2) given by the following definition.

**Definition 1.1 (Exact Controllability).** We say that the system (1.2) is exactly controllable if for any initial data \((u_0^1, u_1^1, \cdots, u_n^0, u_n^1) \in (H^1_0(\Omega) \times L^2(\Omega))^n\) and any target data \((U_0^1, U_1^1, \cdots, U_0^n, U_n^1) \in (H^1_0(\Omega) \times L^2(\Omega))^n\), there exists a control function \(f \in L^2([0,T] \times \omega)\) such that the solution of the system (1.2) with initial data

\[
(u_1, \partial_t u_1, \cdots, u_n, \partial_t u_n)|_{t=0} = (u_0^1, \cdots, u_n^1)
\]

satisfies \((u_1, \partial_t u_1, \cdots, u_n, \partial_t u_n)|_{t=T} = (U_1^0, \cdots, U_n^1)\).

Moreover, we also consider the partial exact controllability for the system (1.2) given by the following definition.

**Definition 1.2.** Let \(\Pi\) be a projection operator of \((H^1_0(\Omega) \times L^2(\Omega))^n\). We say that the system (1.2) is \(\Pi\)-exact controllable if for any initial data \((u_0^1, u_1^1, \cdots, u_n^0, u_n^1) \in (H^1_0(\Omega) \times L^2(\Omega))^n\) and any target data \((U_0^1, U_1^1, \cdots, U_0^n, U_n^1) \in (H^1_0(\Omega) \times L^2(\Omega))^n\), there exists a control function \(f \in L^2([0,T] \times \omega)\) such that the solution of (1.2) with initial data \((u_1, \partial_t u_1, \cdots, u_n, \partial_t u_n)|_{t=0} = (u_0^1, u_1^1, \cdots, u_n^0, u_n^1)\) satisfies

\[
\Pi(u_1, \partial_t u_1, \cdots, u_n, \partial_t u_n)|_{t=T} = (U_1^0, \cdots, U_n^0, U_n^1).
\]

If we only impose that \(\Pi(u_1, \partial_t u_1, \cdots, u_n, \partial_t u_n)|_{t=T} = 0\), we say that the system (1.2) is \(\Pi\)-null controllable.

**Proposition 1.3.** For the system (1.2), the \(\Pi\)-null controllability is equivalent to the \(\Pi\)-exact controllability.

**Proof.** We follow closely the proof of [14, Theorem 2.41]. It is clear that \((\Pi\text{-exact controllability}) \implies (\Pi\text{-null controllability})\). So we focus on the proof of the converse. We define the operator

\[
\mathcal{A} = \begin{pmatrix}
0 & -1 & \cdots & 0 \\
-\Delta K_1 & 0 & \cdots & 0 \\
\vdots & \vdots & 0 & -1 \\
0 & 0 & -\Delta K_n & 0
\end{pmatrix},
\]

the system (1.2) is equivalent to

\[
\partial_t y = -\mathcal{A} y + \hat{B} f 1_{[0,T]}(t) 1_\omega(x), y|_{t=0} = y(0),
\]

(1.4)
where

\[
y(t) = \left( \begin{array}{c}
u_1 \\ \partial_t u_1 \\
\vdots \\
u_n \\ \partial_t u_n 
\end{array} \right), \quad y(0) = \left( \begin{array}{c}
u_1^0 \\ u_1^0 \\
\vdots \\
u_n^0 \\ u_n^1 
\end{array} \right) \quad \text{and} \quad \tilde{B} = \left( \begin{array}{c}0 \\ b_1 \\
\vdots \\
0 \\ b_n 
\end{array} \right).
\]

Let us consider \(S(t)\) the semi-group generated by \(\mathcal{A}\). Let \(y^0 \in (H^1_0(\Omega) \times L^2(\Omega))^n\) and \(y^1 \in (H^1_0(\Omega) \times L^2(\Omega))^n\). Since the system (1.2) is \(\Pi\)–null controllable, we obtain that there exists \(f\) such that the solution \(\tilde{y}\) of the Cauchy problem

\[
\partial_t \tilde{y} = -\mathcal{A} \tilde{y} + \tilde{B} f 1_{]0,T[}(t)1_\omega(x), \quad y|_{t=0} = y^0 - S(-T)y^1
\]

satisfies \(\Pi \tilde{y}(T) = 0\). For the Cauchy problem

\[
\partial_t y = -\mathcal{A} y + \tilde{B} f 1_{]0,T[}(t)1_\omega(x), \quad y|_{t=0} = y^0,
\]

the solution \(y\) is given by

\[
y(t) = \tilde{y}(t) + S(t-T)y^1, \quad \forall t \in [0,T].
\]

Hence, we obtain that \(y(T) = \tilde{y}(T) + y^1\). In particular, we know that \(\Pi y(T) = \Pi y^1\) since \(\Pi \tilde{y}(T) = 0\). We now obtain the \(\Pi\)–exact controllability for the system (1.2).

According to the Hilbert Uniqueness Method of J.-L. Lions [26], the controllability property is equivalent to an observability inequality for the adjoint system. In particular, when we focus on our system (1.2), the exact controllability is equivalent to proving the following observability inequality: \(\exists C > 0\) such that for any solution of the adjoint system:

\[
\begin{aligned}
\Box_{K_1} v_1 &= 0 \quad \text{in } ]0,T[\times\Omega, \\
\Box_{K_2} v_2 &= 0 \quad \text{in } ]0,T[\times\Omega, \\
&\vdots \\
\Box_{K_n} v_n &= 0 \quad \text{in } ]0,T[\times\Omega, \\
v_j &= 0 \quad \text{on } ]0,T[\times\partial\Omega, 1 \leq j \leq n, \\
v_j(0, x) &= v^0_j(x), \quad \partial_t v_j(0, x) = v^1_j(x), 1 \leq j \leq n,
\end{aligned}
\]

we have

\[
C \int_0^T \int_\omega |b_1 k_1 v_1 + \cdots + b_n k_n v_n|^2 dxdt \geq \sum_{i=1}^n (|v^0_i|^2_{L^2} + |v^1_i|^2_{H^{-1}}).
\]

For the partial controllability, we have a similar result. The \(\Pi\)–exact controllability of the system (1.2) is equivalent to proving the following observability inequality: \(\exists C > 0\) such that for any solution of the adjoint system:

\[
\begin{aligned}
\Box_{K_1} v_1 &= 0 \quad \text{in } ]0,T[\times\Omega, \\
\Box_{K_2} v_2 &= 0 \quad \text{in } ]0,T[\times\Omega, \\
&\vdots \\
\Box_{K_n} v_n &= 0 \quad \text{in } ]0,T[\times\Omega, \\
v_j &= 0 \quad \text{on } ]0,T[\times\partial\Omega, 1 \leq j \leq n, \\
(v_1(0, x), \partial_t v_1(0, x), \cdots, v_n(0, x)\partial_t v_n(0, x)) &= \Pi^* V^0
\end{aligned}
\]

where
where \( V^0 \in (L^2 \times H^{-1})^n \) and \( \Pi^* \) is the adjoint operator of the projector \( \Pi \), we have

\[
C \int_0^T \int_\omega |b_1 \kappa_1 v_1 + \cdots + b_n \kappa_n v_n|^2 dx dt \geq ||\Pi^* V^0||^2_{(L^2 \times H^{-1})^n}.
\]

This is an easy consequence of Proposition 1.3, the conservation of energy for system (1.2) and [7, Chapter 4, Proposition 2.1].

In order to study the observability inequality, a classical method is to follow the abstract three-step process initialized by Rauch and Taylor [32] (see also [9]). It can be detailed as follows:

- Firstly, get the microlocal information on the observable region. Argue by contradiction to obtain different kinds of convergence in subdomain \([0, T] \times \omega\) and the whole domain \([0, T] \times \Omega\).

- Secondly, use microlocal defect measure (which is due to Gérard [18] and Tartar [33]), or propagation of singulaties theorem (see [21] Section 18.1) to prove a weak observability estimate:

\[
\sum_{i=1}^n (||v_i^0||^2_{L^2} + ||v_i^1||^2_{H^{-1}}) \\
\leq C \left( \int_0^T \int_\omega |\sum_{j=1}^n b_j \kappa_j v_j|^2 dx dt + \sum_{i=1}^n (||v_i^0||^2_{H^{-1}} + ||v_i^1||^2_{H^{-2}}) \right).
\]

- Thirdly, use unique continuation properties of eigenfunctions to obtain the original observability inequality (1.9).

For the high frequency estimates, a very natural condition is to assume that the control set satisfies the Geometric Control Condition (GCC).

**Definition 1.4.** For \( \omega \subset \Omega \) and \( T > 0 \), we shall say that the pair \((\omega, T, p_K)\) satisfies GCC if every general bicharacteristic of \( p_K \) meets \( \omega \) in a time \( t < T \), where \( p_K \) is the principal symbol of \( \Box_K \).

We will give the definition of bicharacteristics in Section 3. This condition was raised by Bardos, Lebeau, and Rauch [8] when they considered the controllability of a scalar wave equation and has now become a basic assumption for the controllability of wave equations. In [12], the authors show that the geometric control condition is a necessary and sufficient condition for the exact controllability of the wave equation with Dirichlet boundary conditions and continuous boundary control functions. In order to study the low frequencies, we need to introduce the notion of unique continuation of eigenfunctions.

**Definition 1.5.** We say the system (1.2) satisfies the unique continuation of eigenfunctions if the following property holds: \( \forall \lambda \in \mathbb{C} \), the only solution \((\phi_1, \cdots, \phi_n) \in (H^0_0(\Omega))^n \) of

\[
\begin{cases} 
-\Delta_{K_1} \phi_1 = \lambda^2 \phi_1 \ in \ \Omega, \\
-\Delta_{K_2} \phi_2 = \lambda^2 \phi_2 \ in \ \Omega, \\
\vdots \\
-\Delta_{K_n} \phi_n = \lambda^2 \phi_n \ in \ \Omega, \\
b_1 \kappa_1 \phi_1 + \cdots + b_n \kappa_n \phi_n = 0 \ in \ \omega,
\end{cases}
\]

is the zero solution \((\phi_1, \cdots, \phi_n) \equiv 0 \).
There is a large literature on the controllability and observability of the wave equations. Several techniques have been applied to derive observability inequalities in various situations. This paper is mainly devoted to multi-speed wave systems coupled by the control functions only. For other interesting situations, we list some of the existing results and references:

- For single wave equation, it is by now well-known that Bardos, Lebeau, and Rauch [9] use microlocal analysis to prove the (1.9)-type observability inequality for a scalar wave equation. Other approaches for proving it can also be found in the literature, for example, using multipliers [27, 22], using Carleman estimates [20, 10], or completely constructive proof [23], etc.

- Although we now have a better picture on the controllability of a single wave equation, the controllability of systems of wave equations is still not totally understood. To our knowledge, most of the references concern the case of systems with the same principal symbol. Alabau-Boussouira and Léautaud [5] studied the indirect controllability of two coupled wave equations, in which their controllability result was established using a multi-level energy method introduced in [2], and also used in [3, 4]. Liard and Lissy [25], Lissy and Zuazua [28] studied the observability and controllability of the coupled wave systems under the Kalman type rank condition. Moreover, we can find other controllability results for coupled wave systems, for example, Cui, Laurent, and Wang [15] studied the observability of wave equations coupled by first or zero order terms on a compact manifold. The microlocal defect measure when dealing with the single wave equation can also be extended to a system case. One can refer to Burq and Lebeau for the microlocal defect measure for systems [13].

- As for multi-speed case, Dehman, Le Roussau, and Léautaud considered two coupled wave equations with multi-speeds in [16]. More related work is given by Tebou [34], in which the author considered the simultaneous controllability of constant multi-speed wave system and derived some result in a semilinear setting in [35].

1.1. Plan of the paper. The paper is organized as follows. Our main results are in Section 2 and Section 3 is devoted to introducing some geometric preliminaries. We include the descriptions of the boundary points, and give the precise definition of general bicharacteristics and the order of tangential contact with the boundary.

In Section 4, we focus on the high frequency estimates. Subsection 4.1 is devoted to introducing the microlocal defect measure and its basic properties, which is also the main tool for our proof. Subsection 4.2 deals with the partial controllability, and Subsection 4.3 is aimed to recover the exact controllability result in the whole energy space of initial conditions with the help of the unique continuation properties of eigenfunctions. In these two sections, we prove the Theorem 2.1, and Theorem 2.5 respectively.

In Section 5, we plan to deal with low frequency estimates, mainly discussing about the unique continuation properties of eigenfunctions. Subsection 5.1 provides a counterexample to show that only assuming the hypotheses in Theorem 2.1 cannot ensure the unique continuation properties of eigenfunctions. Then, we add some stronger assumptions to obtain the unique continuation property. The first attempt is to require an analyticity condition, which is the example in Proposition 5.3. The
other attempt is to require constant coefficients in Subsection 5.2 and Subsection 5.3, which is stated in Theorem 2.8. Subsection 5.4 is about generic properties of metrics which ensure the unique continuation in dimension 1 and 2.

In Section 6, we deal with the constant coefficient case with multiple control functions. We also discuss the corresponding Kalman rank condition in this setting.

In Appendix A, we include the proof of the equivalent condition of the Kalman rank condition in the case of multiple control functions.

1.2. Ideas of the proof. In our paper, we prove the controllability result by applying the Hilbert uniqueness method to prove the observability inequality of the adjoint system. In order to study the observability inequality, we always use an argument by contradiction. First, we try to prove a weak observability inequality by adding some low frequency part. To obtain the original observability inequality, we need to analyse the invisible solutions in the subdomain \( \omega \times [0,T] \) by proving the unique continuation properties of eigenfunctions. In section 4, we discuss some generic properties. We follow the ideas given by Uhlenbeck [36], using the transversality theorem to obtain generic properties.

2. Main results

In this paper, we mainly study the exact controllability for the system (1.2) and discuss the optimality of the given conditions. On the other hand, when we consider the constant coefficient case, we associate the controllability with the Kalman rank condition. Instead of considering the exact controllability, we can only consider the high frequency estimates to obtain a partial result. One can also see similar finite codimensional controllability results, for instance, in [15] and [29].

**Theorem 2.1.** Given \( T > 0 \), suppose that:

1. \( (\omega, T, p_{K_i}) \) satisfies GCC, \( i = 1, 2, \cdots, n \),
2. \( K_1 > K_2 > \cdots > K_n \) in \( \omega \),
3. \( \Omega \) has no infinite order of tangential contact on the boundary.

Then, there exists a finite dimensional subspace \( E \subset (H^1_0(\Omega) \times L^2(\Omega))^n \) such that the system (1.2) is \( P \)–exactly controllable, where \( P \) is the orthogonal projector on \( E^\perp \).

We will explain the concept of the order of contact in the section 3.

**Remark 2.2.** We say that \( K_1 > K_2 \) in \( \omega \) if and only if \( \forall x \in \omega, \forall \xi \in \mathbb{R}^d \) and \( \xi \neq 0 \), \((\xi, K_1(x)\xi) > (\xi, K_2(x)\xi)\), where \((\cdot, \cdot)\) denotes the inner product of \( \mathbb{R}^d \).

**Remark 2.3.** The Assumption (2) can be generalized as follows: let \( \sigma \) be a permutation of \( \{1, 2, \cdots, n\} \), \( K_{\sigma(1)} > K_{\sigma(2)} > \cdots > K_{\sigma(n)} \) in \( \omega \).

**Remark 2.4.** The same result holds for the laplacian operator

\[
\Delta_{K,\kappa} = \frac{1}{\kappa(x)} \text{div}(\kappa(x)K(x)\nabla \cdot),
\]

where we only assume that \( \kappa \in C^\infty(\Omega) \) without the restriction \( \kappa(x) = \frac{1}{\sqrt{\text{det}(K(x))}} \).

To obtain the exact controllability, we need more assumptions on the low frequency part.

**Theorem 2.5.** Given \( T > 0 \), suppose that:
Theorem 2.8. Given $T > 0$, suppose that:

1. $(\omega, T, p_{K_i})$ satisfies GCC, $i = 1, 2, \ldots, n$,
2. $K_1 > K_2 > \ldots > K_n$ in $\omega$,
3. $\Omega$ has no infinite order of tangential contact on the boundary,
4. The system (1.2) satisfies the unique continuation property of eigenfunctions.

Then the system (1.2) is exactly controllable in $(H^1_0(\Omega) \times L^2(\Omega))^n$.

Now, we consider the particular case of constant coefficients. Define the diagonal matrix $D = \begin{pmatrix} d_1 & & \\ & \ddots & \\ & & d_n \end{pmatrix}$ and $B = \begin{pmatrix} b_1 \\ \vdots \\ b_n \end{pmatrix}$. We use $\Delta$ to denote the canonical Laplace operator. Now we consider the simultaneous control problem for the system:

\[
\partial_t^2 U - D\Delta U = B f 1_{[0,T]}(t) 1_\omega(x) \text{ in }]0, T[ \times \Omega,
\]

where $U = \begin{pmatrix} u_1 \\ \vdots \\ u_n \end{pmatrix}$. This system can be written as

\[
\begin{cases}
(\partial_t^2 - d_1 \Delta) u_1 = b_1 f 1_{[0,T]}(t) 1_\omega(x) \text{ in }]0, T[ \times \Omega, \\
\vdots \\
(\partial_t^2 - d_n \Delta) u_n = b_n f 1_{[0,T]}(t) 1_\omega(x) \text{ in }]0, T[ \times \Omega, \\
u_j = 0 \text{ on }]0, T[ \times \partial \Omega, 1 \leq j \leq n, \\
u_j(0, x) = u_j^0(x), \quad \partial_t u_j(0, x) = u_j^1(x), 1 \leq j \leq n.
\end{cases}
\]

First, we introduce the Kalman rank condition for the system (2.1).

**Definition 2.6** (Kalman rank condition). Define $[D|B] = [D^{n-1}B| \ldots |DB|B]$. We say $(D, B)$ satisfies the Kalman rank condition if and only if $[D|B]$ is full rank.

**Remark 2.7.** In our setting, $(D, B)$ satisfies the Kalman rank condition if and only if all $d_j$ are distinct and $b_j \neq 0$, $1 \leq j \leq n$ (See [6, Remark 1.1]).

**Theorem 2.8.** Given $T > 0$, suppose that:

1. $(\omega, T, p_{K_i})$ satisfies GCC, $i = 1, 2, \ldots, n$,
2. $\Omega$ has no infinite order of tangential contact on the boundary.

Then the system (2.1) is exactly controllable in $(H^1_0(\Omega) \times L^2(\Omega))^n$ if and only if $(D, B)$ satisfies the Kalman rank condition.

**Remark 2.9.** Let $T_0$ be the controllability time corresponding to the wave equation with unit speed of propagation. Then the controllability time in the Theorem 2.8 satisfies $T > T_0 \max \{ \frac{1}{\sqrt{d_j}} ; j = 1, 2, \ldots, n \}$.

In advance, we consider the case with multiple control functions $f_1, f_2, \ldots, f_m (1 \leq m \leq n)$. To be more specific, we consider the system:

\[
\begin{cases}
\partial_t^2 U - D\Delta U = BF 1_{[0,T]}(t) 1_\omega(x) \text{ in }]0, T[ \times \Omega, \\
U|_{\partial \Omega} = 0, \\
(U, \partial_t U)|_{t=0} = (U^0, U^1).
\end{cases}
\]
where \( D = \text{diag}(d_1, d_2, \cdots, d_n) \), \( F = \begin{pmatrix} f_1 \\ \vdots \\ f_m \end{pmatrix} \), and \( B = \begin{pmatrix} b_{11} & \cdots & b_{1m} \\ \vdots & \ddots & \vdots \\ b_{nm} \end{pmatrix} \). We can also define the Kalman rank condition \( \text{rank}[D|B] = n \). Here we recall that \([D|B] = (D^{n-1}B|D^{n-2}B| \cdots |DB|B)\). We have the following theorem:

**Theorem 2.10.** Given \( T > 0 \), suppose that:

1. \( (\omega, T, p_i) \) satisfies GCC, \( i = 1, \cdots, n \).
2. \( \Omega \) has no infinite order of contact on the boundary.

Then the system (2.2) is exactly controllable if and only if \( (D, B) \) satisfies the Kalman rank condition.

### 3. Geometric Preliminaries

Let \( B = \{ y \in \mathbb{R}^d : |y| < 1 \} \) be the unit ball in \( \mathbb{R}^d \). In a tubular neighbourhood of the boundary, we can identify \( M = \Omega \times \mathbb{R} \) locally as \([0, 1] \times B \). More precisely, for \( z \in \overline{M} = \overline{\Omega} \times \mathbb{R} \), we note that \( z = (x, y) \), where \( x \in [0, 1] \) and \( y \in B \) and \( z \in \partial M = \partial \Omega \times \mathbb{R} \) if and only if \( z = (0, y) \). Now we consider \( R = R(x, y, D_y) \) which is a second order scalar, self-adjoint, classical, tangential and smooth pseudo-differential operator, defined in a neighbourhood of \([0, 1] \times B \) with a real principal symbol \( r(x, y, \eta) \), such that

\[
(3.1) \quad \frac{\partial r}{\partial \eta} \neq 0 \text{ for } (x, y) \in [0, 1] \times B \text{ and } \eta \neq 0.
\]

Let \( Q_0(x, y, D_y), Q_1(x, y, D_y) \) be smooth classical tangential pseudo-differential operators defined in a neighbourhood of \([0, 1] \times B \), of order 0 and 1, and principal symbols \( q_0(x, y, \eta), q_1(x, y, \eta) \), respectively. Denote \( P = (\partial_x^2 + R)Id + Q_0 \partial_x + Q_1 \). The principal symbol of \( P \) is

\[
(3.2) \quad p = -\xi^2 + r(x, y, \eta).
\]

We use the usual notations \( TM \) and \( T^*M \) to denote the tangent bundle and cotangent bundle corresponding to \( M \), with the canonical projection \( \pi : TM (\text{ or } T^*M) \rightarrow M \).

Denote \( r_0(y, \eta) = r(0, y, \eta) \). Then we can decompose \( T^*\partial M \) into the disjoint union \( \mathcal{E} \cup \mathcal{G} \cup \mathcal{H} \), where

\[
(3.3) \quad \mathcal{E} = \{ r_0 < 0 \}, \quad \mathcal{G} = \{ r_0 = 0 \}, \quad \mathcal{H} = \{ r_0 > 0 \}.
\]

The sets \( \mathcal{E}, \mathcal{G}, \mathcal{H} \) are called elliptic, glancing, and hyperbolic set, respectively. Define \( \text{Char}(P) = \{(x, y, \xi, \eta) \in T^*\mathbb{R}^{d+1}|_{\overline{M}} : \xi^2 = r(x, y, \xi, \eta)\} \) to be the characteristic manifold of \( P \). For more details, see [13] and [11].

#### 3.1. Generalised bicharacteristic flow

We begin with the definition of the Hamiltonian vector field. For a symplectic manifold \( S \) with local coordinates \( (z, \zeta) \), a Hamiltonian vector field associated with a real valued smooth function \( f \) is defined by the expression:

\[
H_f = \frac{\partial f}{\partial \zeta} \frac{\partial}{\partial z} - \frac{\partial f}{\partial z} \frac{\partial}{\partial \zeta}.
\]

Considering the principal symbol \( p \), we can also consider the associated Hamiltonian \( H_p \), denoted by \( \gamma \), is called a
bicharacteristic of \( p \). Our next goal is to study the behavior of the bicharacteristic near the boundary. To describe the different phenomena when a bicharacteristic approaches the boundary, we need a more accurate decomposition of the glancing set \( G \). Let \( r_1 = \partial_x r|_{x=0} \). Then we can define the decomposition \( G = \bigcup_{j=2}^{\infty} G^j \), with

\[
G^2 = \{(y, \eta) : r_0(y, \eta) = 0, r_1(y, \eta) \neq 0\},
\]

\[
G^3 = \{(y, \eta) : r_0(y, \eta) = 0, r_1(y, \eta) = 0, H_{r_0}(r_1) \neq 0\},
\]

\[
G^{k+3} = \{(y, \eta) : r_0(y, \eta) = 0, H_{r_0}^k(r_1) = 0, \forall j \leq k, H_{r_0}^{k+1}(r_1) \neq 0\},
\]

\[
G^\infty = \{(y, \eta) : r_0(y, \eta) = 0, H_{r_0}^j(r_1) = 0, \forall j\}.
\]

Here \( H_{r_0}^j \) is just the vector field \( H_{r_0} \) composed \( j \) times. Moreover, for \( G^2 \), we can define \( G^{2,\pm} = \{(y, \eta) : r_0(y, \eta) = 0, \pm r_1(y, \eta) > 0\} \). Thus \( G^2 = G^{2,+} \cup G^{2,-} \). For \( \rho \in G^{2,+} \), we say that \( \rho \) is a gliding point and for \( \rho \in G^{2,-} \), we say that \( \rho \) is a diffractive point. For \( \rho \in G^j, j \geq 2 \), we say that a bicharacteristic of \( p \) tangentially contact the boundary \( \{x = 0\} \times B \) with order \( j \) at the point \( \rho \).

Consider a bicharacteristic \( \gamma(s) \) with \( \pi(\gamma(0)) \in M \) and \( \pi(\gamma(s_0)) \in \partial M \) be the first point which touches the boundary. Then if \( \gamma(s_0) \in H \), we can define \( \xi^{\pm}(\gamma(s_0)) = \pm \sqrt{r_0(\gamma(s_0))} \), which are the two different roots of \( \xi^2 = r_0 \) at the point \( \gamma(s_0) \). Notice that the bicharacteristic with the direction \( \xi^- \) will leave the domain \( M \) while the bicharacteristic with the other direction \( \xi^+ \) will enter into the interior of \( M \). This leads to a definition of the broken bicharacteristics(See [21] Section 24.2 for more details):

**Definition 3.1.** A broken bicharacteristic of \( p \) is a map:

\[
s \in I \setminus D \mapsto \gamma(s) \in T^*M \setminus \{0\}
\]

where \( I \) is an interval on \( \mathbb{R} \) and \( D \) is a discrete subset, such that

1. If \( J \) is an interval contained in \( I \setminus D \), then for \( s \in J \mapsto \gamma(s) \) is a bicharacteristic of \( p \) in \( M \).
2. If \( s \in D \), then the limits \( \gamma(s^+) \) and \( \gamma(s^-) \) exist and belongs to \( T^*_zM \setminus \{0\} \) for some \( z \in \partial M \), and the projections in \( T^*_z\partial M \setminus \{0\} \) are the same hyperbolic point.

If \( \gamma(s_0) \in G \), we have different situations. If \( \gamma(s_0) \in G^{2,+} \), then \( \gamma(s) \), locally near \( s_0 \), passes transversally and enters into \( T^*M \) immediately. If \( \gamma(s_0) \in G^{2,-} \) or \( \gamma(s_0) \in G^{k} \) for some \( k \geq 3 \), then \( \gamma(s) \) will continue inside \( T^*\partial M \) and follow the Hamiltonian flow of \( H_{r_0} \). To be more precise, we have the definition of the generalized bicharacteristics(See [21] Section 24.3 for more details):

**Definition 3.2.** A generalized bicharacteristic of \( p \) is a map:

\[
s \in I \setminus D \mapsto \gamma(s) \in T^*M \cup G
\]

where \( I \) is an interval on \( \mathbb{R} \) and \( D \) is a discrete subset \( I \) such that \( p \circ \gamma = 0 \) and the following properties hold:

1. \( \gamma(s) \) is differentiable and \( \frac{d\gamma}{ds} = H_p(\gamma(s)) \) if \( \gamma(s) \in T^*M \) or \( \gamma(s) \in G^{2,+} \).
2. **Every** \( t \in D \) \textit{is isolated} \( i.e. \) there exists \( \epsilon > 0 \) such that \( \gamma(s) \in T^*\overline{M} \setminus T^*\partial M \) if \( 0 < |s - t| < \epsilon \), and the limits \( \gamma(s^\pm) \) are different points in the same hyperbolic fiber of \( T^*\partial M \).

3. \( \gamma(s) \) is differentiable and \( \frac{d\gamma}{ds} = H_{-r_0}(\gamma(s)) \) if \( \gamma(s) \in G \setminus G^2 \).

**Remark 3.3.** We denote the Melrose cotangent compressed bundle by \( ^bT^*\overline{M} \) and the associated canonical map by \( j : T^*\overline{M} \mapsto ^bT^*\overline{M} \). \( j \) is defined by \( j(x, y, \xi, \eta) = (x, y, x\xi, \eta) \).

**Remark 3.3.** We denote the Melrose cotangent compressed bundle by \( ^bT^*\overline{M} \) and the associated canonical map by \( j : T^*\overline{M} \mapsto ^bT^*\overline{M} \). \( j \) is defined by

\[
j(x, y, \xi, \eta) = (x, y, x\xi, \eta).
\]

Under this map \( j \), one could see \( \gamma(s) \) as a continuous flow on the compressed cotangent bundle \( ^bT^*\overline{M} \). This is the so-called Melrose-Sjöstrand flow.

From now on we always assume that there is no infinite tangential contact between the bicharacteristic of \( p \) and the boundary. This is in the meaning of the following definition:

**Definition 3.4.** We say that there is no infinite contact between the bicharacteristics of \( p \) and the boundary if there exists \( N \in \mathbb{N} \) such that the gliding set \( G \) satisfies

\[
G = \bigcup_{j=2}^{N} G^j.
\]

It is well-known that under this hypothesis there exists a unique generalized bicharacteristic passing through any point. This means that the Melrose-Sjöstrand flow is globally well-defined. One can refer to [30] and [31] for the proof.

**4. High Frequency Estimates**

4.1. Microlocal defect measure. In this section, we introduce the microlocal defect measures based on the article by Gérard and Leichtnam [19] for Helmholtz equation and Burq [11] for wave equations. Let \((u^k)_{k \in \mathbb{N}} \in L^2_{loc}(\mathbb{R}_t; L^2(\Omega))\) be a bounded sequence, converging weakly to 0 and such that

\[
\left\{\begin{array}{l}
Pu^k = o(1)_{H^{-1}}, \\
u^k|_{\partial M} = 0.
\end{array}\right.
\]

Let \( u^k \) be the extension by 0 across the boundary of \( \Omega \). Then the sequence \( u^k \) is bounded in \( L^2_{loc}(\mathbb{R}_t; L^2(\mathbb{R}^d)) \). Let \( A \) be the space of classical polyhomogeneous pseudo-differential operators of order 0 with compact support in \( \mathbb{R}_t \times \mathbb{R}^d \) (i.e., \( A = \varphi A \varphi \) for some \( \varphi \in C_0^\infty(\mathbb{R}_t \times \mathbb{R}^d) \)). Let us denote by \( \mathcal{M}^+ \) the set of non-negative Radon measures on \( T^*(\mathbb{R}_t \times \mathbb{R}^d) \). From [11, Section 1], we have the existence of the microlocal defect measure as follows:

**Proposition 4.1** (Existence of the microlocal defect measure). There exists a subsequence of \((u^k)\) (still noted by \((u^k)\)) and \( \mu \in \mathcal{M}^+ \) such that

\[
\forall A \in \mathcal{A}, \quad \lim_{k \to \infty} (Au^k, u^k)_{L^2} = \langle \mu, \sigma(A) \rangle,
\]

where \( \sigma(A) \) is the principal symbol of the operator \( A \) (which is a smooth function homogeneous of order 2 in the variable \( \xi \), i.e. a function on \( S^*((\mathbb{R}_t \times \mathbb{R}^d)) \)).
Remark 4.2. In the article [24], Lebeau constructed the microlocal defect measure in another approach (see [24, Appendice] for more details). In the article [13], Burq and Lebeau proved the similar existence result [13, Proposition 2.5] in a setting of systems, which can be seen as an extension of Proposition 4.1.

From [11, Théorème 15], we have the following proposition.

Proposition 4.3. For the microlocal defect measure $\mu$ defined above, we have the following properties.

- The measure $\mu$ is supported on the intersection of the characteristic manifold with $\mathbb{R}_t \times \overline{\Omega}$,
  \[
  \text{supp}(\mu) \subset \{(t, x, \tau, \xi); x \in \overline{M}, \tau^2 = t^2 K(x) \xi\}.
  \]
- The measure $\mu$ does not charge the hyperbolic points in $\partial M$,
  \[\mu(\mathcal{H}) = 0.\]
- The measure $\mu$ is invariant by the generalised bicharacteristic flow.

Remark 4.4. Notice first that in [11, Section 3], the author considered the case of solutions to the wave equation at the energy level (bounded in $H^1_{\text{loc}}$, and hence was considering second order operators. However, it is easy to pass from $H^1$ to $L^2$ solutions by applying the operator $\partial_t$ and conversely from $L^2$ to $H^1$ by applying the operator $\partial^{-1}_t$, i.e. if $v$ is an $L^2$ solution, considering the solution $u$ associated to $((\Delta_D)^{-1}(\partial_t v \mid_{t=0}), v \mid_{t=0})$, which of course satisfies $\partial_t u = v$. This procedure amounts to replacing the test operators of order $0$ $A$ by the test operator of order $2$, $B = -\partial_t \circ A \circ \partial_t$, but since $\tau^2$ does not vanish on the characteristic manifold, it is an elliptic factor which changes nothing.

Remark 4.5. Notice also that due to discontinuity of the generalised bicharacteristics when they reflect on the boundary at hyperbolic points (the points corresponding to the left and right limits at $s \in D$), in Definition 3.1, the generalised bicharacteristic flow is not well defined (there are two points above any points corresponding to $s \in D$). However, since the measure $\mu$ does not charge these hyperbolic points, this flow is well defined almost surely and the invariance property makes sense. Notice also that in [11, Appendice], weaker property than invariance (namely that the support is a union of generalised bicharacteristics) is proved. The general result follows from this weaker result by applying the strategy in [24]. In any case, for the purpose of the present article, the invariance of the support would suffice.

4.2. Proof of the Theorem 2.1. Let $V = (v_0^1, v_1^1, \cdots, v_n^0, v_1^n)$. We introduce the following spaces:

- We define $\mathcal{X}_1 = (H^1_0(\Omega) \times L^2(\Omega))^n$ endowed with the norm
  \[
  \|V\|_{\mathcal{X}_1}^2 = \sum_{j=1}^n \int_\Omega (K_j \nabla v_j^0 \cdot \overline{\nabla v_j^0} + |v_j^1|^2) \kappa_j \, dx.
  \]
- We define $\mathcal{K}_0 = (L^2(\Omega) \times H^{-1}(\Omega))^n$ endowed with the norm
  \[
  \|V\|_{\mathcal{K}_0}^2 = \sum_{i=1}^n \int_\Omega |v_i^0|^2 \kappa_i \, dx + < v_i^1, T_K v_i^1 >_{H^{-1}, H^1}.
  \]
where
\[ T_{K_i} : H^{-1}(\Omega) \to H^1_0(\Omega) \]
\[ f \mapsto w \]
is defined as the unique solution \( w \in H^1_0(\Omega) \) to 
\[- \frac{1}{\kappa_i} \text{div}(\kappa_i K_i \nabla T_{K_i} w) = f. \]

- We define \( \mathcal{K}_{-1} = (H^{-1}(\Omega) \times D(-\Delta)')^n \) endowed with the norm
\[ \|V\|_{K_{-1}}^2 = \sum_{i=1}^n < v_i^0, T_{K_i} v_i^0 >_{H^{-1}, H^1_0} + < v_i^1, \tilde{T}_{K_i} v_i^1 >_{D(-\Delta_{K_i})^*, D(-\Delta_{K_i})}, \]
where \( D(-\Delta) \) is the domain of the Laplacian operator with zero Dirichlet boundary condition and \( D(-\Delta)' \) is its dual space, and
\[ \tilde{T}_{K_i} : D(-\Delta)' \to D(-\Delta) \]
\[ \tilde{f} \mapsto \tilde{w} \]
is defined as the unique solution \( \tilde{w} \in D(-\Delta) \) to \((-\Delta_{K_i})^2 \tilde{T}_{K_i} \tilde{w} = \tilde{f}. \)

**Remark 4.6.** For any \( j \in \{1, 2, \ldots, n\} \), \( D(-\Delta_{K_j}) = D(-\Delta) \).

Recall the considered control system:
\[
\begin{align*}
\Box_{K_1} u_1 &= b_1 f_1 1_{[0,T]}(t) \mathbf{1}_\omega(x) \quad \text{in } [0,T] \times \Omega, \\
\Box_{K_2} u_2 &= b_2 f_1 1_{[0,T]}(t) \mathbf{1}_\omega(x) \quad \text{in } [0,T] \times \Omega, \\
&
\vdots \\
\Box_{K_n} u_n &= b_n f_1 1_{[0,T]}(t) \mathbf{1}_\omega(x) \quad \text{in } [0,T] \times \Omega, \\
& u_j = 0 \quad \text{on } ]0,T[ \times \partial \Omega, 1 \leq j \leq n, \\
& (u_1, \partial_t u_1, \ldots, u_n, \partial_t u_n)_{t=0} = U(0).
\end{align*}
\]

(4.4)

Consider the homogeneous system:
\[
\begin{align*}
\Box_{K_1} v_1^h &= 0 \quad \text{in } ]0,T[ \times \Omega, \\
\Box_{K_2} v_2^h &= 0 \quad \text{in } ]0,T[ \times \Omega, \\
&
\vdots \\
\Box_{K_n} v_n^h &= 0 \quad \text{in } ]0,T[ \times \Omega, \\
v_j^h &= 0 \quad \text{on } ]0,T[ \times \partial \Omega, 1 \leq j \leq n, \\
& (v_1^h, \partial_t v_1^h, \ldots, v_n^h, \partial_t v_n^h)_{t=0} = V^h(0) \in \mathcal{K}_1.
\end{align*}
\]

(4.5)

Now, let us define
\[
E = \{ V^h(0) \in \mathcal{K}_1 : (b_1 \kappa_1 v_1^h + \cdots + b_n \kappa_n v_n^h)(t, x) = 0, \text{ for any } t \in ]0,T[, x \in \omega \},
\]
where \((v_1^h, \ldots, v_n^h)\) is the solution to the homogeneous system (4.5). Hence, \( E \) is a closed subspace in \( \mathcal{K}_1 \). Denote the orthogonal projector operator \( \mathbb{P} : \mathcal{K}_1 \to E^\perp. \)

And the adjoint system of System (4.4) is the following system:
\[
\begin{align*}
\Box_{K_1} v_1 &= 0 \quad \text{in } ]0,T[ \times \Omega, \\
\Box_{K_2} v_2 &= 0 \quad \text{in } ]0,T[ \times \Omega, \\
&
\vdots \\
\Box_{K_n} v_n &= 0 \quad \text{in } ]0,T[ \times \Omega, \\
v_j &= 0 \quad \text{on } ]0,T[ \times \partial \Omega, 1 \leq j \leq n, \\
& (v_1, \partial_t v_1, \ldots, v_n, \partial_t v_n)_{t=0} = \mathbb{P}^* V(0) \in \mathcal{K}_0.
\end{align*}
\]

(4.7)
Using inequality (1.11), the $P-$exactly controllability of the system (4.4) is equivalent to proving the following observability inequality:

$$C \int_0^T \int_\omega |b_1 \kappa_1 v_1 + \cdots + b_n \kappa_n v_n|^2 \, dx \, dt \geq ||P^* V(0)||_{L^2_{\tau,0}}^2,$$

where $(v_1, \cdots, v_n)$ is the solution to the adjoint system (4.7).

4.2.1. Step 1: Establish a weak observability inequality. First we want to prove a weak inequality:

$$||P^* V(0)||_{L^2_{\tau,0}}^2 \leq C \left( \int_0^T \int_\omega |b_1 \kappa_1 v_1 + \cdots + b_n \kappa_n v_n|^2 \, dx \, dt + ||P^* V(0)||_{L^2_{\tau,1}}^2 \right),$$

If the above inequality was false, we could get a sequence $(P^* \tilde{V}_k^i)_{k \in \mathbb{N}}$ such that

$$||P^* \tilde{V}_0^i||_{L^2_{\tau,0}} = 1,$$

$$\int_0^T \int_\omega |b_1 \kappa_1 v_1^k + \cdots + b_n \kappa_n v_n^k|^2 \, dx \, dt \to 0, \quad k \to \infty,$$

and

$$||P^* \tilde{V}_0^k||_{L^2_{\tau,1}} \to 0, \quad k \to \infty.$$

Here we use $v_i^k (1 \leq i \leq n)$ to denote the corresponding solution of the system (4.7) with the initial data $P^* \tilde{V}_0^k$. Hence, we obtain $n$ bounded sequences $(v_i^k)_{k \in \mathbb{N}} (1 \leq i \leq n)$. Let $\mu_i$ be the defect measure associated to the sequence $(v_i^k)_{k \in \mathbb{N}}$, by the construction in Subsection 4.1. Notice that in these constructions, each sequence $(v_i^k)_{k \in \mathbb{N}}$ is solution to a particular wave equation

$$\Box K_i v_i^k = 0, \quad v_i^k |_{\partial \Omega} = 0,$$

and in Section 3 this corresponds to different principal symbols $p_i$, different sets $G_i, H_i, E_i$ and different generalised bicharacteristic $\gamma_i$.

From the definition of the measures, we obtain

$$\forall A \in \mathcal{A}, \quad \langle \mu_i, \sigma(A) \rangle = \lim_{k \to \infty} (A v_i^k, u_i^k)_{L^2},$$

where $u_i^k$ is the extension by 0 across the boundary of $\Omega$. From Proposition 4.3 we have

**Lemma 4.7.** Each measure $\mu_i$ is supported on the characteristic manifold

$$\text{Char}(p_i) = \{(t, x, \tau, \xi) \in T^* \mathbb{R} \times \mathbb{R}^d |_{\Omega_i}, \tau^2 - \xi K_i(x) \xi \}$$

and is invariant along the generalised bicharacteristic flow associated to the symbol $p_i = \xi K_i(x) \xi - \tau^2$

**Lemma 4.8.** The measures $\mu_i$ and $\mu_l$ are mutually singular in $[0, T] \times \omega$, for $i \neq l$.

**Remark 4.9.** We recall that two measures $\mu$ and $\nu$ are singular if there exists a measurable set $A$ such that $\mu(A) = 0$ and $\nu(A^c) = 0$.

**Proof.** This follows easily from Lemma 4.7 and the assumption 2 in Theorem 2.5, which implies that over $\omega$, the two characteristic manifolds $\text{Char}(p_i)$ and $\text{Char}(p_l)$ are disjoint. □
Lemma 4.10. For $A \in \mathcal{A}$ with the compact support in $]0, T[\times \omega$, we obtain that for $i \neq l$:

$$\lim_{k \to \infty} \sup_{t \in ]0, T[} \left| (A^k_{\omega_i}, \tilde{u}^k_{\omega_i})_{L^2} \right| = 0. \tag{4.13}$$

Proof. For $\forall (t, x) \in ]0, T[\times \omega$, we have that

$$\text{Char}(p_i) \cap \text{Char}(p_l) = \{0\}, i \neq l.$$ 

Then we choose a cut-off function $\beta_i \in C^\infty(T^*\mathbb{R} \times \mathbb{R}^d)$ homogeneous of degree 0 for $|(|\tau, \xi)| \geq 1$, with compact support in $]0, T[\times \omega$ such that

$$\beta_i|\text{Char}(p_i) = 1, \beta_i|\text{Char}(p_l) = 0, \text{ and } 0 \leq \beta_i \leq 1.$$ 

Since $A \in \mathcal{A}$ with the compact support in $]0, T[\times \omega$, for some $\varphi \in C^\infty_0([0, T[\times \omega)$, we have that $A = \varphi \lambda_\omega$. We choose $\tilde{\varphi} \in C^\infty_0([0, T[\times \omega)$ such that $\tilde{\varphi}|_{\text{supp}(\varphi)} = 1$ i.e., $\tilde{\varphi}\varphi = \varphi$. Now let us consider the $(A^k_{\omega_i}, \tilde{u}^k_{\omega_i})_{L^2}$. First, we have that

$$\left( A^k_{\omega_i}, \tilde{u}^k_{\omega_i} \right)_{L^2} = (\varphi A\varphi L^k_{\omega_i}, \tilde{\varphi} L^k_{\omega_i})_{L^2} = ((1 - \text{Op}(\beta_i))\varphi A\varphi L^k_{\omega_i}, \tilde{\varphi} L^k_{\omega_i})_{L^2} + (\text{Op}(\beta_i)\varphi A\varphi L^k_{\omega_i}, \tilde{\varphi} L^k_{\omega_i})_{L^2}.$$ 

For the first term $((1 - \text{Op}(\beta_i))\varphi A\varphi L^k_{\omega_i}, \tilde{\varphi} L^k_{\omega_i})_{L^2}$, by the Cauchy-Schwarz inequality, therefore we obtain that

$$|((1 - \text{Op}(\beta_i))\varphi A\varphi L^k_{\omega_i}, \tilde{\varphi} L^k_{\omega_i})_{L^2}| \leq \left| \left| (1 - \text{Op}(\beta_i))\varphi A\varphi L^k_{\omega_i} \right| \right| \left| \tilde{\varphi} L^k_{\omega_i} \right|_{L^2}.$$ 

As we know that $\left\{ \tilde{\varphi} L^k_{\omega_i} \right\}$ is bounded in $L^2_{loc}(\mathbb{R} \times \mathbb{R}^d)$, there exists a constant $C$ such that

$$\left| \left| \tilde{\varphi} L^k_{\omega_i} \right| \right|_{L^2} = \left( \tilde{\varphi} L^k_{\omega_i}, \tilde{\varphi} L^k_{\omega_i} \right)_{L^2} \leq C.$$ 

From the definition of the measure $\mu_i$, we obtain

$$\lim_{k \to \infty} \left| \left| (1 - \text{Op}(\beta_i))\varphi A\varphi L^k_{\omega_i} \right| \right|_{L^2} = \lim_{k \to \infty} \left| \left| (1 - \text{Op}(\beta_i))\varphi A\varphi L^k_{\omega_i}, (1 - \text{Op}(\beta_i))\varphi A\varphi L^k_{\omega_i} \right| \right|_{L^2} = \langle \mu_i, (1 - \beta_i)^2 \varphi |\sigma(A)|^2 \rangle.$$

From Proposition 4.3, we have that $\text{supp} (\mu_i) \subset \text{Char}(p_i)$. In addition, by the choice of $\beta_i$, we know that $1 - \beta_i \equiv 0$ on $\text{supp} (\mu_i)$, which implies that $\langle \mu_i, (1 - \beta_i)^2 \varphi |\sigma(A)|^2 \rangle = 0$. Hence, we obtain

$$\lim_{k \to \infty} \left| \left| (1 - \text{Op}(\beta_i))\varphi A\varphi L^k_{\omega_i}, \tilde{\varphi} L^k_{\omega_i} \right| \right|_{L^2} = 0. \tag{4.14}$$

The other term $(\text{Op}(\beta_i)\varphi A\varphi L^k_{\omega_i}, \tilde{\varphi} L^k_{\omega_i})_{L^2} = (L^k_{\omega_i}, \varphi A^* \varphi \text{Op}(\beta_i)^* \tilde{\varphi} L^k_{\omega_i})_{L^2}$ is dealt with similarly by exchanging $i$ and $l$. \hfill \Box

Now let us come back to the proof of the weak observability inequality (4.9). By the assumption (4.11), We know that

$$\int_0^T \int_\omega \left| b_1 \kappa_1 v^k_1 + \ldots + b_n \kappa_n v^k_n \right|^2 dx dt \to 0,$$

for $\chi \in C_0^\infty(\omega \times ]0, T[)$, and we would like to obtain:

$$\sum_{1 \leq i, j \leq n} \langle \chi b_1 \kappa_i v^k_i, \chi b_1 \kappa_j v^k_j \rangle \to 0, \text{ as } k \to \infty.$$
According to Lemma 4.10, we know that for $i \neq l$,
\begin{equation}
\lim_{k \to \infty} \sup_{T} |\langle \chi b_{l, i} v_{i}^{k}, \chi b_{l, i} v_{i}^{k} \rangle| = 0.
\end{equation}

As a consequence, we know that
\begin{equation}
\lim_{k \to \infty} \sup_{T} \sum_{i=1}^{n} |\langle \chi b_{l, i} v_{i}^{k}, \chi b_{l, i} v_{i}^{k} \rangle| = 0.
\end{equation}

Using again the definition of the measure $\mu_{i}$, we obtain the following:
\begin{equation}
0 \leq \langle \mu_{i}, (\chi b_{l, i})^{2} \rangle = \lim_{k \to \infty} \langle \chi b_{l, i} v_{i}^{k}, \chi b_{l, i} v_{i}^{k} \rangle \leq \lim_{k \to \infty} \sum_{i=1}^{n} \langle \chi b_{l, i} v_{i}^{k}, \chi b_{l, i} v_{i}^{k} \rangle = 0.
\end{equation}

Thus, we know that
\[ \mu_{i}|_{\omega \times [0, T]} = 0. \]

Since $\mu_{i}$ is invariant along the general bicharacteristics of $p_{K_{i}}$ (by Lemma 4.7), combining with GCC, we know that $\mu_{i} \equiv 0$. Since $\mu_{i} = 0$, we have $v_{i}^{k} \to 0$ strongly in $L_{\text{loc}}^{2}(]0, T[\times \Omega)$. Now we have to estimate $||\partial_{t} v_{i}^{k}(0)||_{H^{-1}}$. Let $\chi \in C_{0}^{\infty}(]0, T[)$. Multiply the equation
\[ \Box_{K_{1}} v_{1} = 0 \]
by $T_{K_{1}}(\chi^{2} v_{1}^{k})$ and then integrate on $]0, T[\times \Omega$. We obtain that
\begin{equation}
0 = \int_{0}^{T} \int_{\Omega} \Box_{K_{1}} v_{1}^{k} \cdot T_{K_{1}}(\chi^{2} v_{1}^{k}) \, dx \, dt
= \int_{0}^{T} \int_{\Omega} v_{1}^{k} \cdot (\Delta_{K_{1}} T_{K_{1}}(\chi^{2} v_{1}^{k})) \, dx \, dt - \int_{0}^{T} \int_{\Omega} \partial_{t} v_{1} \cdot T_{K_{1}}(\partial_{t}(\chi^{2} v_{1}^{k})) \, dx \, dt
- \int_{0}^{T} ||\chi \partial_{t} v_{1}^{k}||_{H^{-1}}
= ||\chi v_{1}^{k}||_{L^{2}}^{2} - \int_{0}^{T} ||\chi \partial_{t} v_{1}^{k}||_{H^{-1}}^{2} + \int_{0}^{T} \int_{\Omega} v_{1}^{k} \cdot T_{K_{1}}(\partial_{t}^{2}(\chi^{2} v_{1}^{k}) + \partial_{t}(\chi^{2}) \partial_{t} v_{1}^{k}) \, dx \, dt
\end{equation}

For the term $\int_{0}^{T} \int_{\Omega} v_{1}^{k} \cdot T_{K_{1}}(\partial_{t}^{2}(\chi^{2} v_{1}^{k}) + \partial_{t}(\chi^{2}) \partial_{t} v_{1}^{k}) \, dx \, dt$, we know that $v_{1}^{k} \to 0$ strongly in $L_{\text{loc}}^{2}(]0, T[\times \Omega)$ and $T_{K_{1}}(\partial_{t}^{2}(\chi^{2} v_{1}^{k}) + \partial_{t}(\chi^{2}) \partial_{t} v_{1}^{k})$ is bounded in $L^{2}$. Thus, up to a subsequence, it tends to 0 as $k \to \infty$. Hence, we obtain that:
\[ \int_{0}^{T} ||\chi \partial_{t} v_{1}^{k}||_{H^{-1}}^{2} \to 0, \quad \text{as} \quad k \to \infty. \]

So for all $0 < t_{1} < t_{2} < T$,
\[ \int_{t_{1}}^{t_{2}} ||\partial_{t} v_{1}^{k}(t)||_{H^{-1}}^{2} \, dt \to 0. \]

So for almost every $t \in ]t_{1}, t_{2}[$, $||\partial_{t} v_{1}^{k}(t)||_{H^{-1}} + ||v_{1}^{k}(t)||_{L^{2}} \to 0$. Then by the backward well-posedness, we can conclude:
\[ ||\partial_{t} v_{1}^{k}(0)||_{H^{-1}} + ||v_{1}^{k}(0)||_{L^{2}}^{2} \to 0. \]

The same reasoning holds for $v_{j}^{k}$, $2 \leq j \leq n$. This gives a contradiction with (4.10), which proves the weak observability inequality (4.9).
4.2.2. Step 2: Descriptions of the space $E$. Define

$$\mathcal{N}(T) = \{F^*V(0) \in \mathcal{K}_0 : (b_1 \kappa_1 v_1 + \cdots + b_n \kappa_n v_n)(t, x) = 0, \text{ for } t \in ]0, T[, x \in \omega \}.$$  

**Lemma 4.11.** $E = \mathcal{N}(T)$ where $E$ was defined in (4.6) and $E$ has a finite dimension.

**Proof.** According to the weak observability inequality (4.9), for $F^*V(0) \in \mathcal{N}(T)$, we obtain that

$$||F^*V(0)||^2_{\mathcal{K}_0} \leq C||F^*V(0)||^2_{\mathcal{K}_0}.$$  

We know that $\mathcal{N}(T)$ is a closed subspace of $\mathcal{K}_0$. By the compact embedding $\mathcal{K}_0 \hookrightarrow \mathcal{K}_1$, we know that $\mathcal{N}(T)$ has a finite dimension. By definition, we know that $E \subset \mathcal{N}(T)$. Hence, we obtain that $E$ has a finite dimension. Then we want to show that $E = \mathcal{N}(T)$. Define

$$\mathcal{A} = \begin{pmatrix} 0 & -1 & \cdots & 0 \\ -\Delta \kappa_1 & 0 & \cdots & 0 \\ \vdots & \vdots & 0 & -1 \\ 0 & 0 & -\Delta \kappa_n & 0 \end{pmatrix}.$$  

Thus, the solution $(v_1, \partial_t v_1, \cdots, v_n, \partial_t v_n)^t$ can be written as

$$\begin{pmatrix} v_1 \\ \partial_t v_1 \\ \vdots \\ v_n \\ \partial_t v_n \end{pmatrix} = e^{-t\mathcal{A}}F^*V(0).$$  

Since $\mathcal{N}(T)$ is of finite dimension, it is complete for any norm. Setting $\delta > 0$, we know that (4.19) is still true for $F^*V(0) \in \mathcal{N}(T - \delta)$. Taking $F^*V(0) \in \mathcal{N}(T)$, for $\epsilon \in ]0, \delta[$, we have $e^{-\epsilon \mathcal{A}}F^*V(0) \in \mathcal{N}(T - \delta)$. For $\alpha$ large enough, as $\epsilon \to 0^+$,

$$(\alpha + \mathcal{A})^{-1} \frac{1}{\epsilon} (\text{Id} - e^{-\epsilon \mathcal{A}})F^*V(0) \to \mathcal{A}(\alpha + \mathcal{A})^{-1}F^*V(0).$$  

As a consequence, we obtain $\mathcal{N}(T) \subset D(\mathcal{A}) \subset \mathcal{K}_1$. Hence, we obtain that $E = \mathcal{N}(T)$ and has a finite dimension. \hfill \Box

4.2.3. Step 3: Proof of the observability inequality (4.8). If (4.8) was false, we could find a sequence $\{F^*V^k(0)\}_{k \in \mathbb{N}} \subset \mathcal{K}_0$ such that

$$||F^*V^k(0)||_{\mathcal{K}_0} = 1, \quad \int_0^T ||b_1 \kappa_1 v_1^k + \cdots + b_n \kappa_n v_n^k||^2_{L^2(\omega)} dt \to 0.$$  

First, we know that $\{F^*V^k(0)\}_{k \in \mathbb{N}}$ is bounded in $\mathcal{K}_0 = (L^2 \times H^{-1})^n$. Hence, there exists a subsequence (also denoted by $F^*V^k(0)$) weakly converging in $\mathcal{K}_0 = (L^2 \times H^{-1})^n$, to a limit which we denote with $F^*V(0)$. We also know that $F^*V(0)$ leads to a solution $(v_1, \cdots, v_n)$ of the system (4.7) and satisfies $b_1 \kappa_1 v_1 + \cdots + b_n \kappa_n v_n = 0$ in $]0, T[ \times \omega$. Thus, we know that $F^*V(0) \in \mathcal{N}(T) = E$, which implies that $F^*V(0) = 0$. Since the embedding $\mathcal{K}_0 \hookrightarrow \mathcal{K}_{-1}$ is compact, we obtain that $||F^*V^k(0)||^2_{\mathcal{K}_{-1}} \to ||F^*V(0)||^2_{\mathcal{K}_{-1}}$. From the weak observability inequality (4.9), we obtain:

$$1 \leq C||F^*V(0)||^2_{\mathcal{K}_{-1}},$$
which contradicts to the fact that $\mathbb{P}^* V(0) = 0$. Then observability inequality (4.8) follows. This concludes the proof of the $\mathbb{P}$–exact controllability of the system (4.4).

4.3. The Proof of Theorem 2.5. According to the proof above, we only need to show that $E^\perp = \{0\}$, which is equivalent to $\mathbb{P}^* = Id$. If we denote by $\hat{V}(t)$ the solution of

$$\partial_t \hat{V} + \mathcal{A} \hat{V} = 0, \hat{V}|_{t=0} = V(0),$$

then, $\mathcal{A} V(0) = -\partial_x \hat{V}|_{t=0} \in \mathcal{N}(T)$ provided that $V(0) \in \mathcal{N}(T)$. This implies that $\mathcal{A} \mathcal{N}(T) \subset \mathcal{N}(T)$. Since $\mathcal{N}(T)$ is a finite dimensional closed subspace of $D(\mathcal{A})$, and stable by the action of the operator $\mathcal{A}$, it contains an eigenfunction of $\mathcal{A}$. To be specific, there exists $(e_1, e_2, \ldots, e_n) \in \mathcal{N}(T)$ and $\lambda \in \mathbb{C}$ such that

$$(\begin{array}{cccc}
0 & -1 & \cdots & 0 \\
-\Delta_{K_1} & 0 & \cdots & 0 \\
\vdots & \vdots & 0 & -1 \\
0 & 0 & -\Delta_{K_n} & 0
\end{array})
(\begin{array}{c}
e_1^0 \\
e_1^1 \\
n \vdots \\
ne_n^1
\end{array})
= \lambda
(\begin{array}{c}
e_1^0 \\
e_1^1 \\
n \vdots \\
ne_n^1
\end{array}).$$

It is equivalent to the following system:

$$
\begin{align*}
-e_1^1 &= \lambda e_1^0 \text{ in } \Omega, \\
-\Delta_{K_1} e_1^0 &= \lambda e_1^1 \text{ in } \Omega, \\
\cdots \\
-e_n^1 &= \lambda e_n^0 \text{ in } \Omega, \\
-\Delta_{K_n} e_n^0 &= \lambda e_n^1 \text{ in } \Omega, \\
b_1 \kappa_1 e_1^0 + \cdots + b_n \kappa_n e_n^0 &= 0, \text{ in } \omega.
\end{align*}
$$

(4.21)

We can simplify this into

$$
\begin{align*}
\Delta_{K_1} e_1^0 &= \lambda^2 e_1^0 \text{ in } \Omega, \\
\Delta_{K_2} e_2^0 &= \lambda^2 e_2^0 \text{ in } \Omega, \\
\cdots \\
\Delta_{K_n} e_n^0 &= \lambda^2 e_n^0 \text{ in } \Omega, \\
b_1 \kappa_1 e_1^0 + \cdots + b_n \kappa_n e_n^0 &= 0 \text{ in } \omega,
\end{align*}
$$

Since the system satisfies the unique continuation of eigenfunctions, we know that $e_1^0 = \cdots = e_n^0 = 0$ in $\Omega$, which implies that $E = \mathcal{N}(T) = \{0\}$. Hence, from (4.8) with $\mathbb{P}^* = Id$, we obtain the observability inequality

$$C \int_0^T \int_\omega |b_1 \kappa_1 v_1 + \cdots + b_n \kappa_n v_n|^2 dx dt \geq ||V(0)||_{\mathcal{X}_0}^2.$$

This concludes the proof of Theorem 2.5.

5. Unique continuation of eigenfunctions

5.1. A counterexample. First, we construct an example to show that the conditions in Theorem 2.1 are not sufficient to ensure the unique continuation of eigenfunctions. Now, let us focus on the unique continuation problem in dimension 1.
We consider a smooth metric in dimension 1, \( g = c(x)dx^2 \). Then we can define the Laplace-Beltrami operator in the sense:

\[
\Delta_g = \frac{1}{\sqrt{\det(g)}} \frac{d}{dx} (\sqrt{\det(g)} g^{-1} \frac{d}{dx})
\]

(5.1)

\[
= \frac{1}{c} \frac{d}{dx^2} - \frac{c' d}{2c^2 dx}
\]

Fix the open interval \([0, \pi]\) and the subinterval \([a, b] \subset [0, \pi]\) \((a > \frac{\pi}{2})\). Now we consider the unique continuation problem:

\[
\begin{align*}
  u''_1 &= -\lambda^2 u_1, \\
  \Delta_g u_2 &= -\lambda^2 u_2, \\
  u_1 + u_2 &= 0 \text{ on } [a, b], \\
  u_1, u_2 &\in H^1_0([0, \pi]).
\end{align*}
\]

(5.2)

In general, the unique continuation of eigenfunctions does not hold.

**Theorem 5.1.** There exists a smooth Riemannian metric \( g = c(x)dx^2 \), and two eigenfunctions \( u_1, u_2 \) of \( \Delta_g \) and \( \frac{d^2}{dx^2} \) on \([0, \pi]\) associated with eigenvalue 1 such that \( u_1 + u_2 = 0 \) in \([a, b] \subset [0, \pi]\) and \( u_1 + u_2 \neq 0 \) in \([0, \pi]\).

**Proof.** Let \( \chi \in C^\infty(\R) \) satisfying the following conditions:

1. \( \chi(0) = \chi(\pi) = 0; \)
2. \( 0 < \chi \leq K \) on \([0, \pi]\) and \( \chi(\frac{\pi}{2}) = K > 1; \)
3. \( \chi(x) = 1, \forall x \in [a, b]; \)
4. \( \chi'(x) > 0 \) for \( x \in [0, \frac{\pi}{2}] \), \( \chi'(x) < 0 \) for \( x \in [b, \pi] \) and \( \chi'(x) < 0 \) for \( x \in (\pi, a[ \]

Define \( u_2(x) = -\chi(x) \sin x \). Hence, we obtain \( u_2(x) = -\sin x \) on \([a, b]\) and \( u_2'(x) = -\chi'(x) \sin x - \chi(x) \cos x \). Then we define \( c(x) \) by

\[
c(x) = \frac{(\chi'(x) \sin x + \chi(x) \cos x)^2}{K^2 - \chi^2 \sin^2 x},
\]

(5.3)

with a constant \( K > 1 \). It is easy to check that \( c \geq 0 \). Since we want \( g \) to be a Riemannian metric, we need \( c > 0 \). Let us discuss in different cases,

1. if \( x \in [0, \frac{\pi}{2}] \), we know that \( \chi'(x) > 0, \chi(x) > 0 \). Hence, we have \( \chi'(x) \sin x + \chi(x) \cos x > 0; \)
2. if \( x \in [a, b], \chi'(x) = 0, \chi(x) = 1 \), we obtain \( \chi'(x) \sin x + \chi(x) \cos x = \cos x < 0 \) since \( a > \frac{\pi}{2} \);
3. if \( x \in [b, \pi[ \), we know that \( \chi'(x) < 0, \chi(x) > 0 \). Hence, we have \( \chi'(x) \sin x + \chi(x) \cos x < 0; \)
4. if \( x \in (\frac{\pi}{2}, a[ \), we know that \( \chi'(x) < 0, \chi(x) > 0 \). Hence, we have \( \chi'(x) \sin x + \chi(x) \cos x < 0; \)
5. if \( x = \frac{\pi}{2}, \chi'(\frac{\pi}{2}) = 0, c(\frac{\pi}{2}) = 1 - \frac{\chi''(\frac{\pi}{2})}{K} \geq 1. \)

So we can conclude that \( c > 0 \) and \( g \) is a Riemannian metric.

We want to show that \( c \) is \( C^\infty \) near \( \frac{\pi}{2} \). Let \( f(x) = (\chi'(x) \sin x + \chi(x) \cos x)^2 \) and \( g(x) = K^2 - \chi^2 \sin^2 x \), then we obtain \( c(x) = \frac{4}{g} \). We claim that there exist \( \tilde{f}, \tilde{g} \in C^\infty \) and \( \tilde{f}(\frac{\pi}{2}) \neq 0, \tilde{g}(\frac{\pi}{2}) \neq 0 \) such that \( f(x) = (x - \frac{\pi}{2})^2 \tilde{f}(x) \) and \( g(x) = (x - \frac{\pi}{2})^2 \tilde{g}(x) \).
We just use the Taylor expansion of $\chi, \chi'$, sin and cos:

\[
\chi(x) = K + \frac{1}{2}\chi''(\frac{x}{2})(x - \frac{\pi}{2})^2 + R_1(x), \\
\chi'(x) = \chi''(\frac{\pi}{2})(x - \frac{\pi}{2}) + \frac{1}{2}\chi''(\frac{\pi}{2})(x - \frac{\pi}{2})^2 + R_2(x), \\
\sin(x) = 1 - \frac{1}{2}(x - \frac{\pi}{2})^2 + R_3(x), \\
\cos(x) = -(x - \frac{\pi}{2}) + R_4(x),
\]

where $\lim_{x \to \frac{\pi}{2}} \frac{R_j}{(x - \frac{\pi}{2})^2} = 0$, for $j = 1, 2, 3, 4$. Then we obtain:

\[
\begin{align*}
    f(x) &= ((\chi''(\frac{\pi}{2}) - K)^2 + \tilde{R}_1)(x - \frac{\pi}{2})^2; \\
    g(x) &= (-K(\chi''(\frac{\pi}{2}) - K) + \tilde{R}_2)(x - \frac{\pi}{2})^2.
\end{align*}
\]

Here $\lim_{x \to \frac{\pi}{2}} \tilde{R}_j = 0$ for $j = 1, 2$. Now if we choose a small neighbourhood of $\frac{\pi}{2}$, then $\tilde{f} = (\chi''(\frac{\pi}{2}) - K)^2 + \tilde{R}_1$ and $\tilde{g} = -K(\chi''(\frac{\pi}{2}) - K) + \tilde{R}_2$ satisfy the property. So we know $c$ is $C^\infty$ and $c > 0$, which means that $g$ is a smooth Riemannian metric. In addition, $c < 1$ in $]a, b]$ and $\Delta_g$ and $\Delta$ admit the same eigenfunction in this interval $]a, b]$.

\[\square\]

**Remark 5.2.** In fact, we can construct a counterexample in any dimension $d \geq 1$. For example, we define $\mathcal{M} = ]0, \pi[ \times \Pi^{d-1}_y$ where $\Pi^{d-1}_y$ is the torus of dimension $d - 1$. Then consider two metric $g_1 = dx^2 + \sum_{j=0}^{d-1} dy_j^2$ and $g_2 = c(x) dx^2 + \sum_{j=0}^{d-1} dy_j^2$ where $c(x) dx^2$ is the metric we constructed in the dimension 1. Take the same $u_1(x)$ and $u_2(x)$ in the proof of Theorem 5.1. Let $V$ be the eigenfunction of $\sum_{j=1}^{d-1} \frac{d^2}{dy_j^2}$ associated with eigenvalue $\alpha$ in $\Pi^{d-1}_y$. Then

\[
\begin{cases}
    -\Delta_{g_1}(u_1(x)V(y)) = (\alpha + 1)u_1(x)V(y), \\
    -\Delta_{g_2}(u_2(x)V(y)) = (\alpha + 1)u_2(x)V(y), \\
    u_1(x)V(y) + u_2(x)V(y) = 0, \text{ in } ]a, b[ \times \Pi^{d-1}_y, \\
    u_1(x)V(y), u_2(x)V(y) \in H^1_0(M).
\end{cases}
\]

But we know $u_1(x)V(y) + u_2(x)V(y) \not\equiv 0$ in $M$.

As we have seen, not every smooth metric can give us the unique continuation of eigenfunctions. Here, we will give a positive result under a strong condition of analyticity. In particular, let us consider the example of two equations:

\[
\begin{cases}
    \Box_{K_1} u_1 = b_1 f_1|_{\Omega}(t) 1_\omega(x) \text{ in } ]0, T[ \times \Omega \\
    \Box_{K_2} u_2 = b_2 f_1|_{\Omega}(t) 1_\omega(x) \text{ in } ]0, T[ \times \Omega \\
    u_j = 0 \quad \text{ on } ]0, T[ \times \partial \Omega, j = 1, 2, \\
    u_j(0, x) = u_j^0(x), \quad \partial_t u_j(0, x) = u_j^1(x), j = 1, 2.
\end{cases}
\]

**Proposition 5.3.** Given $T > 0$, suppose that:

1. $(\omega, T, p_{K_i})$ satisfies GCC, $i = 1, 2$.
2. $K_1 > K_2$ in $\Omega$ with analytic coefficients.
3. There exists a constant $c$ such that density functions $\kappa_1, \kappa_2$ are analytic and $\kappa_1 = c\kappa_2$.
4. $\Omega$ has no infinite order of contact on the boundary.
Then the system (5.6) is exactly controllable.

Proof. According to Theorem 2.1, we only need to show the unique continuation of eigenfunctions of system (5.6):

\[
\begin{cases}
-\Delta K_1 u_1 = \lambda^2 u_1 \text{ in } \Omega, \\
-\Delta K_2 u_2 = \lambda^2 u_2 \text{ in } \Omega, \\
cu_1 + u_2 = 0 \text{ in } \omega.
\end{cases}
\] (5.7)

Since $K_1$ and $K_2$ have analytic coefficients, we know $u_1$ and $u_2$ are analytic functions. Then $cu_1 + u_2$ is also analytic. By unique continuation for analytic functions, $cu_1 + u_2 = 0$ in the whole domain $\Omega$. By the relations of two density functions $\kappa_1 = c\kappa_2$, we have:

\[
\Delta K_1 u_1 = \frac{1}{\kappa_1(x)} \text{div}(\kappa_1(x) K_1 \nabla u_1)
\]

\[
= \frac{1}{c\kappa_2(x)} \text{div}(c\kappa_2(x) K_1 \nabla u_1)
\]

\[
= \frac{1}{\kappa_2(x)} \text{div}(\kappa_2(x) K_1 \nabla u_1).
\] (5.8)

Then

\[
-c\Delta K_1 u_1 - \Delta K_2 u_2 = -\frac{c}{\kappa_2(x)} \text{div}(\kappa_2(x) K_1 \nabla u_1) - \frac{1}{\kappa_2(x)} \text{div}(\kappa_2(x) K_2 \nabla u_2)
\]

\[
= -\frac{c}{\kappa_2(x)} \text{div}(\kappa_2(x) K_1 \nabla u_1) + \frac{c}{\kappa_2(x)} \text{div}(\kappa_2(x) K_2 \nabla u_1)
\]

\[
= -\frac{c}{\kappa_2(x)} \text{div}(\kappa_2(x)(K_1 - K_2) \nabla u_1).
\]

On the other hand, we know $-c\Delta K_1 u_1 - \Delta K_2 u_2 = \lambda^2(cu_1 + u_2) = 0$. Hence, we have:

\[
-\frac{1}{\kappa_2(x)} \text{div}(\kappa_2(x)(K_1 - K_2) \nabla u_1) = 0.
\]

We recall that $-\frac{1}{\kappa_2(x)} \text{div}(\kappa_2(x)(K_1 - K_2) \nabla \cdot )$ is an elliptic operator. Hence, with $u_1|_{\partial \Omega} = 0$ on the boundary, we know that $u_1 = 0$. Hence, we deduce $u_2 = -cu_1 = 0$ in $\Omega$, which gives $N(T) = 0$. \hfill \Box

5.2. Constant Coefficient Case. In this section, we consider the simultaneous control problem for the system:

\[
\partial_t^2 U - D \Delta U = B f 1_{]0,T[}(t) 1_\omega(x) \text{ in } [0, T \times \Omega},
\] (5.9)

where $U = \begin{pmatrix} u_1 \\ \vdots \\ u_n \end{pmatrix}$, $B = \begin{pmatrix} b_1 \\ \vdots \\ b_n \end{pmatrix}$ and $D = \text{diag}(d_1, \ldots, d_n)$. Then the system can be written as

\[
\begin{cases}
(\partial_t^2 - d_1 \Delta) u_1 = b_1 f 1_{]0,T[}(t) 1_\omega(x) \text{ in } [0, T \times \Omega}, \\
\vdots \\
(\partial_t^2 - d_n \Delta) u_n = b_n f 1_{]0,T[}(t) 1_\omega(x) \text{ in } [0, T \times \Omega}, \\
u_j = 0 \text{ on } [0,T \times \partial \Omega, 1 \leq j \leq n, \\
u_j(0, x) = u_j^0(x), \quad \partial_t u_j(0, x) = u_j^1(x), 1 \leq j \leq n.
\end{cases}
\]
Recall that the Kalman rank condition for this case is \( \text{rank}[D|B] = n \) if and only if all \( d_j \) are distinct and \( b_j \neq 0 \), \( 1 \leq j \leq n \) (See [6]). Without loss of generality, we may assume that \( d_1 < d_2 < \cdots < d_n \). We want to prove the exact controllability for this case (Theorem 2.8).

5.3. Proof of Theorem 2.8. By Theorem 2.1, we only need to prove the unique continuation properties for eigenfunctions. Here we only state some facts without repeating the same trick as before. Define

\[
\mathcal{N}(T) = \{ \mathcal{Y} \in (L^2 \times H^{-1})^n : (b_1v_1 + b_2v_2 + \cdots + b_nv_n)(x, t) = 0, \forall (x, t) \in ]0, T[ \times \omega \}. 
\]

Then, \( \mathcal{N}(T) \) is a finite dimensional closed subspace of \( D(\mathcal{A}) \), and stable by the action of the operator \( \mathcal{A} \); it contains an eigenfunction of \( \mathcal{A} \), where \( \mathcal{A} = \begin{pmatrix} 0 & -Id \\ -D\Delta & 0 \end{pmatrix} \).

Thus there exist \( \beta \in \mathbb{C} \) and \( \mathcal{V}_\beta = (V_1, V_2) \) such that \( \mathcal{A}\mathcal{V}_\beta = \beta \mathcal{V}_\beta \), i.e.

\[
(5.10) \quad -\Delta V_1 = -\beta^2 D^{-1}V_1
\]

If \( \beta \neq 0 \), \((-\beta^2)^{-k}(-\Delta)^k V_1 = D^{-k}V_1 \) and \((-\Delta)^k B^t V_1 = (-\beta^2)^k B^t D^{-k}V_1 \). Since \( V_1 \) solves the Laplace eigenvalue problem, we know that \( V_1 \) is analytic in \( \Omega \) which ensures that \( B^t V_1 = b_1v_1 + \cdots + b_nv_n = 0 \) in the whole domain \( \Omega \). Thus

\[
(5.11) \quad 0 = [B^t V_1]((-\beta^2)^{-1}(-\Delta)B^t V_1) \cdots |(-\beta^2)^{-n}(-\Delta)^n B^t V_1| = [D|B|^t D^{1-n}V_1
\]

Since \( \text{rank}[D|B] = n \), it is invertible. This gives that \( V_1 = 0 \).

If \( \beta = 0 \), we immediately obtain that \( V_1 = 0 \) by the boundary condition.

Now we assume that the matrix \((D, B)\) does not satisfy the Kalman rank condition. Then we know that either there exist \( d_j \) and \( d_j \) such that \( d_{j_1} = d_{j_2} \), or there exists som\( b_j = 0 \). We want to show the unique continuation property fails in both cases. One can refer to [17] for more details.

For the first case \( b_j = 0 \), we know that

\[
(\partial_t^2 - d_j \Delta) u_j = 0 \text{ in } ]0, T[ \times \Omega,
\]

by the conservation of energy, the solution \( u_j \) cannot be zero at any time if the initial data is not zero.

For the second case, we consider the unique continuation property of the eigenfunctions as follows:

\[
\begin{align*}
-d_1 \Delta \phi_1 &= \lambda^2 \phi_1 \text{ in } \Omega, \\
\vdots \\
-d_{j_1} \Delta \phi_{j_1} &= \lambda^2 \phi_{j_1} \text{ in } \Omega, \\
-d_{j_2} \Delta \phi_{j_2} &= \lambda^2 \phi_{j_2} \text{ in } \Omega, \\
\vdots \\
-d_n \Delta \phi_n &= \lambda^2 \phi_n \text{ in } \Omega, \\
\phi_j &= 0 \text{ on } \partial \Omega, 1 \leq j \leq n, \\
b_1 \phi_1 + \cdots + b_n \phi_n &= 0 \text{ in } \omega,
\end{align*}
\]

Since we have the relation \( d_{j_1} = d_{j_2} \), we know that there exists a non-zero solution \((0, \cdots, 0, \phi, -b_j \phi, 0, \cdots, 0)\), where \( \phi \) is an eigenfunction for \(-d_j \Delta \) of eigenvalue \( \lambda^2 \). Hence, we cannot obtain the exact controllability in this case.

To conclude, we have obtained that the Kalman rank condition is a sufficient and necessary condition for the exact controllability.
5.4. Two Generic Properties. If we define $\Delta_{K_1} = \Delta = \frac{\partial^2}{\partial x^2}$ and $n = 2$, we have shown that not every smooth metric can give us a unique continuation result in dimension 1 (see Subsection 5.1). Then we want to prove a generic property for the metrics which can give the unique continuation result in dimension 1. We introduce the following space of smooth metrics to be sections of a bundle

$$\mathcal{M} = \{ g \in C^\infty(\Omega, T^*\Omega \otimes T^*\Omega) : g(x)(v_x, v_x) > 0, \text{ for } 0 \neq v_x \in T_x\Omega \}.$$ Let $\Omega = [0, \pi[$.

**Proposition 5.4.** In dimension 1, suppose that we fix the Laplacian $\Delta = \frac{\partial^2}{\partial x^2}$ in $[0, \pi[$ with its spectrum $\sigma(\Delta)$. Then the set $\mathcal{G}_{uc} = \{ g \in \mathcal{M} : \sigma(\Delta_g) \cap \sigma(\Delta) = \emptyset \}$ is residual in $\mathcal{M}$.

**Proof.** First, we notice that any connected one dimensional Riemannian manifold is diffeomorphic either to $\mathbb{R}$ or to $S^1$. We already know that $\sigma(\Delta) = \{ k^2 \}_{k \in \mathbb{N}}$. In our setting, we have $g = c(x)dx^2$. Then by change of variables, $y = \int_0^x \sqrt{c(s)}ds$. Then $\frac{dy}{dx} = \frac{dc}{c(x)}dx = \frac{1}{\sqrt{c(x)}} \frac{d}{dx}$. Hence, we obtain $\frac{d^2}{dy^2} = \frac{1}{\sqrt{c(x)}} \frac{d}{dx} \frac{d}{dx} = \Delta_g$. Define $L = \int_0^\pi \sqrt{c(s)}ds$. Hence, $\sigma(\Delta_g) = \sigma(\frac{d^2}{dy^2}) = \{ k^2 \}_{k \in \mathbb{N}}$. If $\sigma(\Delta_g) \cap \sigma(\Delta) \neq \emptyset$, we obtain that for some $k$ and $l$, $L = k^2 \in \pi \mathbb{Q}$, i.e. $\int_0^\pi \sqrt{c(x)}dx \in \pi \mathbb{Q}$. \hfill $\square$

**Corollary 5.5.** Fix $\Delta = \frac{\partial^2}{\partial x^2}$, for every metric $g \in \mathcal{G}_{uc}$, the system (5.2) has a unique solution $u_1 = u_2 = 0$.

**Proof.** By the definition of $\mathcal{G}_{uc}$, we know $\sigma(\Delta_g) \cap \sigma(\Delta) = \emptyset$. Consider a solution $u_1$, $u_2$ of

$$\begin{cases} u_1'' = -\lambda^2 u_1, \\ \Delta_g u_2 = -\lambda^2 u_2, \\ u_1 + u_2 = 0 \text{ in } [a, b], \\ u_1, u_2 \in H^1_0([0, \pi]). \end{cases}$$

Now, assume that $u_1 = 0$. Then $u_2 = 0$ in $[a, b]$. Hence, by the unique continuation property for the eigenfunctions, we know that $u_2 = 0$. This means that the system has only trivial solution in this case. It is the same for $u_2 = 0$.

Assume that $u_1 \neq 0$ then $u_1 \neq 0$ in $[a, b]$ (otherwise $u_1 = 0$ everywhere by the unique continuation property) and therefore $u_2 \neq 0$. Then $u_1$ and $u_2$ are both eigenfunctions. Hence $\lambda^2 \in \sigma(\Delta_g) \cap \sigma(\Delta) = \emptyset$, which is a contradiction. So for every $g \in \mathcal{G}_{uc}$, the system has only the trivial solution $(0, 0)$. \hfill $\square$

From now on and until the end of the section, we restrict to the 2 dimensional case $d = 2$. For any smooth metric $g$, we can define a Laplace-Beltrami operator $-\Delta_g$.

**Definition 5.6.** Define the map:

$$\mathcal{E}^\alpha : H^2(\Omega) \cap H^1_0(\Omega) \times \mathcal{M} \to H^{-1}$$ by $\mathcal{E}^\alpha(u, g) = (\Delta_g + \alpha)u$.

**Remark 5.7.** $-\Delta_g$ is a Fredholm operator of index 0, and $\mathcal{E}^\alpha_g = \mathcal{E}^\alpha(\cdot, g)$ is also a Fredholm map of index 0 (see [36]). Here $\alpha$ is just a parameter. In the later proof, we will let $\alpha$ take all possible values in the spectrum of the given Laplacian.

From now on, we fix one metric $g_0$ and the associated operator $-\Delta_{g_0}$.
Lemma 5.8. For any $\lambda$ fixed and any element $f \in H^{-1}$, $\lambda \notin \sigma(\Delta_g)$ if and only if $f$ is a regular value (i.e. the tangential map at this point is surjective) of $E_\lambda^g : H^2(\Omega) \cap H^1_0(\Omega) \to H^{-1}$.

Proof. Let $E_\lambda^g(u) = E_\lambda^g(u, g) = f$. At this point $u$, the tangential map $D E_\lambda^g : T_u(H^k(\Omega) \cap H^1_0(\Omega)) \to H^{-1}(\Omega)$ is given by $D E_\lambda^g(v) = (\Delta_g + \lambda)v$, since $\Delta_g + \lambda$ is a linear operator. $\lambda \notin \sigma(\Delta_g)$ is equivalent to that $\Delta_g + \lambda$ is bijective, which means $f$ is a regular value of $E_\lambda^g$. $\square$

Our proof mainly rely on the following theorem:

Theorem 5.9 (Transversality theorem). Let $\varphi : H \times B \to E$ be a $C^k$ map, $H$, $B$, and $E$ Banach manifolds with $H$ and $E$ separable. If $f$ is a regular value of $\varphi$ and $\varphi_b = \varphi(\cdot, b)$ is a Fredholm map of index $< k$, then the set \{ $b \in B : f$ is a regular value of $\varphi_b$ \} is residual in $B$.

One can find a proof in [1].

Lemma 5.10. If $\lambda \in \sigma(\Delta_{g_0})$ is a regular value of $E_\lambda^g$, then the set \{ $g \in M : \lambda \notin \sigma(\Delta_g)$ \} is residual in $M$.

Proof. Just apply Theorem 5.9, combining with Lemma 5.8. $\square$

Now we have to check with the hypothesis, that is to verify that $\lambda \in \sigma(-\Delta_{g_0})$ is a regular value for $E_\lambda^g$. In the following, we will use $D_1$ to denote the differential in the direction of $H^2(\Omega) \cap H^1_0(\Omega)$ and $D_2$ to denote the differential in the direction of $M$.

Now let us check that the image of $D_2 E_\lambda^g$ is dense in dimension 2. We will use the conformal variations of the metric $g$. Here we choose $r \in C^\infty_0(\Omega)$

$$D_2 E_\lambda^g(r g) = \lim_{s \to 0} \frac{(\Delta_g + sr g - \Delta_g)}{s} u$$

$$= \lim_{s \to 0} \frac{1}{s} \left( \frac{1}{(1 + sr)g^{ij}} \partial_i[(1 + sr)g^{ij}(1 + sr)^{-1}g^{il} \partial_l u - \Delta_g u] \right)$$

$$= \lim_{s \to 0} \frac{1}{s} \left( \frac{2 - 2}{2} (1 + sr)^{-2} \partial_i r g^{ij} \partial_j u + \frac{1}{1 + sr} \Delta_g u - \Delta_g u \right)$$

$$= -r \Delta_g u$$

(5.12)

Let us assume that $v$ is orthogonal to $D_2 E_\lambda^g(r g)$ for all $r$, then:

$$0 = \int_{\Omega} v D_2 E_\lambda^g(r g) d\mu_g$$

$$= \int_{\Omega} v(-r \Delta_g u) d\mu_g$$

$$= \int_{\Omega} r(\lambda u - \lambda)v d\mu_g.$$ 

Since (5.13) holds for any $r \in C^\infty_0(\Omega)$ we obtain that:

$$\int_{\Omega} (\lambda u - \lambda)v = 0.$$ 

Now, we can check that $\lambda$ is a regular value of $E_\lambda^g$.

Lemma 5.11. In dimension 2, $\lambda \in \sigma(\Delta_{g_0})$ is a regular value of $E_\lambda^g$. 

*Simultaneous Control*
Proof. Let \((u, g)\) satisfy \(\mathcal{E}^\lambda(u, g) = (\Delta_g + \lambda)u = \lambda\), then at the point \((u, g)\), we have
\[
D\mathcal{E}^\lambda(v, h) = (\Delta_g + \lambda)v + D_2\mathcal{E}^\lambda(h).
\]
Now we need to verify the surjectivity of this map. If \(y \in \text{Im}(\Delta_g + \lambda)\), then \(y\) is a weak solution of \((\Delta_g + \lambda)y = 0\), and \(y\) is smooth. Let us assume that \(y\) is orthogonal to \(D_2\mathcal{E}^\lambda(rg)\). Then according to (5.14), we obtain that:
\[
(\lambda u - \lambda)y = 0.
\]
First, we claim that \(u\) cannot be a constant. Assume that \(u\) is a constant function, \(\Delta_g u = 0\) and \((\Delta_g + \lambda)u = \lambda\) gives that \(u = 1\). But this does not satisfy the boundary condition. Hence, \(u\) cannot be a constant. In particular, \(u \neq 1\). Now we obtain that \(\lambda u - \lambda \neq 0\). If \(\lambda u - \lambda \neq 0\) at \(x_0\), there exists a open neighbourhood \(N\) such that \(\lambda u - \lambda \neq 0\) in \(N\). Then \(y = 0\) in \(N\). Hence, we know that \(y\) vanishes in a subdomain of \(\Omega\). Then by the unique continuation property, we know \(y = 0\) in \(\Omega\). This leads to the surjectivity of the map \(D\mathcal{E}^\lambda\), which means that \(\lambda \in \sigma(-\Delta_{g_0})\) is a regular value of \(\mathcal{E}^\lambda\).

Now we can deduce that the set \(G^\lambda = \{g \in \mathcal{M} : \lambda \notin \sigma(\Delta_g)\}\) is residual in \(\mathcal{M}\).

**Proposition 5.12.** In dimension 2, suppose that we fix one metric \(g_0\) and the associated Laplacian \(\Delta_{g_0}\) with its spectrum \(\sigma(\Delta_{g_0})\). Then the set \(G_{uc} = \{g \in \mathcal{M} : \sigma(\Delta_g) \cap \sigma(\Delta_{g_0}) = \emptyset\}\) is residual in \(\mathcal{M}\).

**Proof.** Define:
\[
G_{uc} = \cap_{\lambda \in \sigma(\Delta_{g_0})} G^\lambda.
\]
\(G\) is a intersection of countably many residual sets, so it is still residual in \(\mathcal{M}\). And for any metric \(g \in G_{uc}\), \(\sigma(\Delta_g) \cap \sigma(\Delta_{g_0}) = \emptyset\). Assume that \(\lambda_0 \in \sigma(\Delta_g) \cap \sigma(\Delta_{g_0})\), which gives that \(g \notin G^{\lambda_0}\). That contradicts to the fact that \(g \in G_{uc} = \cap_{\lambda \in \sigma(\Delta)} G^\lambda\). Hence, for fixed Laplacian \(\Delta\) with its spectrum \(\sigma(\Delta_{g_0})\), the set \(\{g \in \mathcal{M} : \sigma(\Delta_g) \cap \sigma(\Delta_{g_0}) = \emptyset\}\) is residual in \(\mathcal{M}\).

**Corollary 5.13.** In dimension 2, fix the canonical Laplace operator \(\Delta\), for every metric \(g \in G_{uc}\), the system
\[
\begin{align*}
\Delta u_1 &= -\lambda^2 u_1, \\
\Delta u_2 &= -\lambda^2 u_2, \\
u_1 + u_2 &= 0 \text{ in } \omega \subset \Omega, \\
u_1, u_2 &\in H_0^1(\Omega),
\end{align*}
\]
has only trivial solution \(u_1 = u_2 = 0\).

6. Constant Coefficient Case with Multiple Control Functions

In this section, we prove **Theorem 2.10.** First we study the information given by the Kalman rank condition. Without loss of generality, we assume that the diagonal matrix \(D\) has the form
\[
D = \begin{pmatrix}
d_1 \text{Id}_{n_1} & & \\
& \ddots & \\
d_s \text{Id}_{n_s}
\end{pmatrix},
\]
where \(\sum_{1 \leq i \leq s} n_i = n\) and
We have that $d_i(1 \leq i \leq s)$ are all distinct. And we can always rearrange the lines of the system (2.2) to ensure that this property is verified:

\[
\begin{align*}
\left\{ \begin{array}{l}
(\partial_t^2 - d_1 \Delta)U_1 = B_1 F \textbf{1}_{[0, T]}(t) \textbf{1}_\omega(x) \text{ in } [0, T] \times \Omega, \\
\vdots \\
(\partial_t^2 - d_s \Delta)U_s = B_s F \textbf{1}_{[0, T]}(t) \textbf{1}_\omega(x) \text{ in } [0, T] \times \Omega,
\end{array} \right.
\]

for every $1 \leq i \leq s$, where $U_i = \begin{pmatrix} u_1^i \\ \vdots \\ u_{n_i}^i \end{pmatrix}$ and $B_i = \begin{pmatrix} b_{i1}^i & \cdots & b_{im}^i \\ \vdots & \ddots & \vdots \\ b_{ni1}^i & \cdots & b_{nimi}^i \end{pmatrix}$ is a matrix of size $n_i \times m$.

**Proposition 6.1.** $(D, B)$ satisfies the Kalman rank condition if and only if $\text{rank}(B_i) = n_i \leq m$.

**Remark 6.2.** If $m = 1$, we know that $\text{rank}(B_i) = n_i \leq 1$. Thus, we obtain $n_i = 1$ and $B_i = b_i \neq 0$. This implies that every entry of control matrix $B$ is nonzero and all speeds $d_i$ are distinct. We recover the result of Remark 1.1 in [6]. If $m \geq 2$, we can allow some block $d_i \text{Id}_{n_i}$ is of size $n_i \times n_i$, with $n_i \geq 2$. For example, take $D = \text{diag}(1, 1, 2)$ and $B = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 0 \end{pmatrix}$. Then we obtain $[D|B] = \begin{pmatrix} 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 1 & 0 \\ 4 & 0 & 2 & 0 & 1 \end{pmatrix}$.

Hence, we know that $\text{rank}[D|B] = 3$ which means that the matrix $[D|B]$ is of full rank.

The proof of Proposition 6.1 is given in the Appendix.

Now we can prove Theorem 2.10.

**Proof of Theorem 2.10.** We follow the same procedure. Applying Hilbert uniqueness method, we can establish the observability inequality:

\[
||V(0)||_{(L^2 \times H^{-1})^n}^2 \leq C \int_0^T \int_\omega |B^*V|^2 dx dt,
\]

where $B^*$ is the adjoint form of the matrix $B$, and $V = (V_1, \cdots, V_s)^t \in \mathbb{R}^{m_1} \times \cdots \times \mathbb{R}^{m_s} = \mathbb{R}^m$. Then we can establish a similar weak observability inequality:

\[
||V(0)||_{(L^2 \times H^{-1})^n}^2 \leq C \int_0^T \int_\omega |B^*V|^2 dx dt + C||V(0)||_{(H^{-1} \times H^{-2})^n}^2.
\]

Then argue by contradiction. Suppose that the weak observability inequality is false, then there exists a sequence $(V^k(0))_{k \in \mathbb{N}}$ such that

\[
||V^k(0)||_{(L^2 \times H^{-1})^n}^2 = 1,
\]

\[
\int_0^T \int_\omega |B^*V^k|^2 dx dt \to 0,
\]

\[
||V^k(0)||_{(H^{-1} \times H^{-2})^n}^2 \to 0.
\]

Hence, there are $s$ microlocal defect measures $(\mu_i)_{i=1}^s$ corresponding to $V_i$.

\[
\int_0^T \int_\omega |B^*V^k|^2 dx dt = \int_0^T \int_\omega \sum_{i=1}^s B_i^* V_i^k|^2 dx dt.
\]
Since \( \mu_i \) and \( \mu_j \) are singular from each other, for \( i \neq j \), we know by Cauchy-Schwarz inequality,

\[
(6.7) \quad \sum_{i=1}^{s} \int_{0}^{T} |B_i^* V_i^k|^2 dt \to 0,
\]

which gives that \( B_i^* \mu_i |_{\omega \times [0,T]} = 0 \). Since \( rank(B_i^*) = rank(B_i) = n_i \), we know \( B_i^* \) is invertible. Hence we know \( \mu_i |_{\omega \times [0,T]} = 0 \). The rest of the proof is similar to the single control case.

\[\square\]

**Appendix A. Proof of Proposition 6.1**

**Proof of Proposition 6.1.** First, we calculate the form of \([D|B]\):

\[
[D|B] = [D^{n-1}B] \cdots [DB|B] = \begin{bmatrix} d_1^{n-1}B_1 & \cdots & B_1 \\ \vdots & \ddots & \vdots \\ d_s^{n-1}B_s & \cdots & B_s \end{bmatrix}
\]

Now we define \( r_i = rank(B_i) \). Thus, for each \( i \), we can find invertible matrices \( P_i \) of size \( n_i \times n_i \) and \( Q_i \) of size \( m \times m \) such that \( P_i B_i Q_i = \begin{pmatrix} \text{Id}_{r_i} & 0 \\ 0 & 0 \end{pmatrix} \). Then define \( P = \text{diag}(P_1, \ldots, P_s) \) and \( Q = \text{diag}(Q_1, \ldots, Q_s) \). We know that \( P \) and \( Q \) are invertible. Hence, we obtain \( rank[D|B] = rank(P[D|B]Q) \). Now we rewrite that

\[
P[D|B]Q = \begin{bmatrix} d_1^{n-1}P_1B_1Q_1 & \cdots & P_1B_1Q_s \\ \vdots & \ddots & \vdots \\ d_s^{n-1}P_sB_sQ_1 & \cdots & P_sB_sQ_s \end{bmatrix}
= \begin{bmatrix} d_1^{n-1}E_1 & \cdots & P_1B_1Q_s \\ \vdots & \ddots & \vdots \\ d_s^{n-1}P_sB_sQ_1 & \cdots & E_s \end{bmatrix}
\]

Now, consider the general term \( P_iB_iQ_j \):

\[
P_iB_iQ_j = P_iB_iQ_j^{-1}Q_j = E_iQ_j^{-1}Q_j.
\]

Hence,

\[
P[D|B]Q = \begin{bmatrix} d_1^{n-1}E_1 & \cdots & E_1Q_j^{-1}Q_s \\ \vdots & \ddots & \vdots \\ d_s^{n-1}E_sQ_j^{-1}Q_1 & \cdots & E_s \end{bmatrix}
\]

Now we define the column transform \( T_1 \):

\[
T_1 = \begin{bmatrix} \text{Id}_{n_1} & -\frac{1}{d_1}Q_1^{-1}Q_2 & \cdots & -\frac{1}{d_1}Q_1^{-1}Q_s \\ 0 & \text{Id}_{n_2} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \text{Id}_{n_s} \end{bmatrix}
\]
It is easy to see that $T_1$ is invertible and $\text{rank}(P[D|B]Q) = \text{rank}(P[D|B]QT_1)$. 

\[
P[D|B]QT_1 = \begin{bmatrix} d_1^{n-1}E_1 & 0 & \cdots & 0 \\ d_2^{n-1}E_2Q_2^{-1}Q_1 & \left(\frac{d_2^{n-1}}{d_2} - \frac{d_2^{n-1}}{d_1}\right)E_2 & \cdots & \left(\frac{d_2^{n-1}}{d_2} - \frac{d_2^{n-1}}{d_1}\right)E_2Q_2^{-1}Q_s \\ \vdots & \vdots & \ddots & \vdots \\ d_s^{n-1}E_sQ_s^{-1}Q_1 & \cdots & \cdots & \left(\frac{d_s^{n-1}}{d_s} - \frac{d_s^{n-1}}{d_1}\right)E_s \\ \end{bmatrix}.
\]

Step by step, we can do the Gaussian elimination and find an invertible matrix $T$ such that:

\[
P[D|B]QT = \begin{bmatrix} d_1^{n-1}E_1 & 0 & \cdots & 0 \\ * & d_2^{n-1}\left(\frac{1}{d_2} - \frac{1}{d_1}\right)E_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ * & * & \cdots & d_s^{n-1}\prod_{i=1}^{s-1}\left(\frac{1}{d_s} - \frac{1}{d_i}\right)E_s \\ \end{bmatrix}.
\]

Then $\text{rank}[D|B] = \text{rank}(P[D|B]Q) = \text{rank}(P[D|B]Q) = \sum_{i=1}^{s} r_i \leq \sum_{i=1}^{s} n_i$. Hence, $n = \text{rank}[D|B] = \sum_{i=1}^{s} r_i \leq \sum_{i=1}^{s} n_i = n$. This implies that $\text{rank}[D|B] = n \iff \forall i, r_i = n_i$. □

Acknowledgments

This work is finished under the guidance of Nicolas Burq and Pierre Lissy, to whom the author owes great gratitude. The author would also express gratitude to Hui Zhu for several interesting discussions and comments.
