Boundary integral formulations for the forward problem in magnetic induction tomography

S. Engleder and O. Steinbach

Communicated by W. Wendland

In this paper we present two models for the forward problem of magnetic induction tomography. In particular, we describe the eddy current model, and a reduced simplified model. The error between the reduced and the full model is analyzed in dependence of parameters such as the frequency and the conductivity. In the case of a piecewise constant conductivity we derive a boundary integral formulation for the reduced model. Finally, we comment on numerical results for the forward problem and give a comparison of both models. Copyright © 2011 John Wiley & Sons, Ltd.

Keywords: magnetic induction tomography; boundary element methods

1. Introduction

Magnetic induction tomography is a non-invasive and contactless imaging method to determine the conductivity and permittivity distribution inside a certain object, like the human body, see, e.g. [1–5]. An array of coils is placed in a ring around the body as depicted in Figure 1. In each coil a time-harmonic current is induced, which generates a time-harmonic magnetic field. This so-called primary magnetic field $B_p$ induces eddy currents inside the body, which perturb the magnetic field. The reconstruction is then based on the measurement of the perturbed voltage in an array of receiver coils around the body.

To describe the forward problem of MIT we use the time-harmonic Maxwell equations for $x \in \mathbb{R}^3$,

$$\nabla \times E(x) = -io\mu \epsilon(x), \quad \nabla \times H(x) = j(x) + io\mu \sigma(x), \quad \nabla \cdot D(x) = 0, \quad \nabla \cdot B(x) = 0,$$

where we consider an isotropic and linear material, i.e.

$$D(x) = \epsilon(x) E(x), \quad B(x) = \mu(x) H(x), \quad j(x) = j_i(x) + \sigma(x) E(x).$$

When considering biologic tissues we may assume a constant permeability $\mu(x) = \mu_0$. The coil is modeled by prescribing a given impressed current $j_i$, of which we assume that it is not influenced by the magnetic reaction fields caused by the eddy currents inside the conducting domain. Hence, we conclude

$$\nabla \times E(x) = -io\mu_0 H(x), \quad \nabla \times H(x) = j_i(x) + \kappa(x) E(x), \quad \nabla \cdot [\epsilon(x) E(x)] = 0, \quad \nabla \cdot H(x) = 0,$$

where

$$\kappa(x) := \sigma(x) + io\epsilon(x)$$

is the complex conductivity. When eliminating the magnetic field $H$, we finally obtain

$$\nabla \times \frac{1}{\mu_0} \nabla \times E(x) + io\kappa(x) E(x) = -ioj_i(x), \quad \nabla \cdot [\epsilon(x) E(x)] = 0 \quad \text{for} \ x \in \mathbb{R}^3.$$

In particular when considering the inverse problem of MIT, for example by using a standard parameter identification approach, the solution of the forward problem depends on the boundary mesh only. Hence it seems to be a natural choice to use a boundary integral equation approach for the approximate solution of the forward problem [6, 7], for finite element methods, see, e.g. [8–10].
This paper is organized as follows: In Section 2 we describe the mathematical model of the forward problem, i.e. the material parameters and the modeling of the excitation coils, and we discuss the eddy current model and a reduced simplified model. Bounds for the approximation error of certain quantities computed with the reduced and the eddy current model are presented in Section 3. In Section 4, a boundary element formulation for the reduced model is given, and some numerical results in Section 5 conclude the paper.

2. Eddy current model

In this section, we formulate the forward problem of MIT by using the eddy current formulation. The use of the eddy current model is justified since the wavelength for operating frequencies of MIT systems, which lie typically between 10 and 100 MHz, is in the range of some micrometers, so the wavelength is small compared to the size of the conductor.

Let $\Omega \subset \mathbb{R}^3$ be a bounded domain, which represents the conducting object, and let $\Omega^c = \mathbb{R}^3 \setminus \bar{\Omega}$ be the exterior domain, where we assume a non-conducting material, e.g. air. For $x \in \Omega^c$ we therefore assume $\varepsilon(x) = 0$. The eddy current model of MIT is obtained by neglecting the displacement currents $\mathbf{D}$ in the non-conducting material domain $\Omega^c$, i.e. we set $\varepsilon(x) = 0$ for $x \in \Omega^c$. Hence, we can rewrite the partial differential equation (2) as a system of two coupled equations,

$$\nabla \times \frac{1}{\mu_0} \nabla \times \mathbf{E}(x) + i\omega \varepsilon(x) \mathbf{E}(x) = -i\omega j(x), \quad \nabla \cdot \varepsilon(x) \mathbf{E}(x) = 0 \quad \text{for } x \in \Omega \tag{3}$$

and

$$\nabla \times \frac{1}{\mu_0} \nabla \times \mathbf{E}(x) = -i\omega j(x) \quad \text{for } x \in \Omega^c, \tag{4}$$

where we introduce the gauging condition

$$\nabla \cdot \mathbf{E}(x) = 0 \quad \text{for } x \in \Omega^c. \tag{5}$$

In addition we assume radiation conditions at infinity, i.e.

$$\mathbf{E}(x) = O(|x|^{-1}), \quad \nabla \times \mathbf{E}(x) = O(|x|^{-1}) \quad \text{as } |x| \to \infty. \tag{6}$$

Moreover, we have to include transmission boundary conditions for $x \in \Gamma = \partial \Omega$,

$$[j(x) \cdot n_x]_{x \in \Gamma} = 0, \quad [\mathbf{H}(x) \times n_x]_{x \in \Gamma} = 0,$$

which can be rewritten as

$$[x(x) \mathbf{E}(x) \cdot n_x]_{x \in \Gamma} = 0, \quad \frac{1}{i\omega \mu_0} [\nabla \times \mathbf{E}(x)] \cdot n_x]_{x \in \Gamma} = 0. \tag{7}$$

Note that the jump is given by

$$[\nu(x)]_{x \in \Gamma} = \lim_{\Omega^c \ni \mathbf{x} \to x \in \Gamma} \nu(\mathbf{x}) - \lim_{\Omega \ni \mathbf{x} \to x \in \Gamma} \nu(\mathbf{x}).$$

For the solution of the transmission problem (3)–(7), we introduce the decomposition

$$\mathbf{E}(x) = \mathbf{E}_s(x) + \mathbf{E}_p(x), \tag{8}$$

where $\mathbf{E}_p$ denotes the primary field generated by the exciting coil $\mathbf{C}$ without the presence of a conducting object. Correspondingly, $\mathbf{E}_s$ is the secondary or reaction field caused by the presence of some conducting material. In particular, the primary field $\mathbf{E}_p$ is a solution of the partial differential equations

$$\nabla \times \nabla \times \mathbf{E}_p(x) = -i\omega \mu_0 j(x), \quad \nabla \cdot \mathbf{E}_p(x) = 0 \quad \text{for } x \in \mathbb{R}^3,$$
which can be written as

\[-\Delta E_p(x) = -i\omega \mu_0 j(x) \quad \text{for} \quad x \in \mathbb{R}^3.\]

Hence, we obtain a particular solution by the Newton potential

\[E_p(x) = -i\omega \mu_0 \frac{1}{4\pi} \int_{\mathbb{R}^3} \frac{J(y)}{|x-y|} dy \quad \text{for} \quad x \in \mathbb{R}^3.\]  

(9)

Hence, instead of (3) and (4) it remains to solve the following system of partial differential equations, i.e. for \(x \in \Omega\)

\[\nabla \times \frac{1}{\mu_0} \nabla \times E_3(x) + i\omega \kappa(x) E_3(x) = -i\omega \kappa(x) E_p(x), \quad \nabla \cdot [\epsilon(x)(E_3(x) + E_p(x))] = 0\]  

(10)

and

\[\nabla \times \nabla \times E_3(x) = 0, \quad \nabla \cdot E_3(x) = 0 \quad \text{for} \quad x \in \Omega^c,\]  

(11)

and with the radiation conditions

\[E_3(x) = \epsilon'(|x|^{-1}), \quad \nabla \times E_3(x) = \epsilon'(|x|^{-1}) \quad \text{as} \quad |x| \to \infty.\]  

(12)

If we define

\[H(\text{curl} \mathbb{R}^3) := \{ U \in L_2(\mathbb{R}^3), \nabla \times U \in L_2(\mathbb{R}^3)\}\]

the variational formulation of the transmission problem (10), (11), and (12) reads to find \(E_3 \in H(\text{curl} \mathbb{R}^3)\) such that

\[\frac{1}{\mu_0} \int_{\mathbb{R}^3} (\nabla \times E_3(x)) \cdot (\nabla \times \mathbf{F}(x)) dx + \text{io} \int_{\Omega} \kappa(x) E_3(x) \cdot \mathbf{F}(x) dx = -\text{io} \int_{\Omega} \kappa(x) E_p(x) \cdot \mathbf{F}(x) dx\]  

(13)

is satisfied for all \(\mathbf{F} \in H(\text{curl} \mathbb{R}^3)\). The null space of the variational problem (13) can be characterized by the function \(E_\phi(x) = 0\) for \(x \in \Omega\) and \(E_\phi(x) = \nabla \phi(x)\) for \(x \in \Omega^c\), where \(\phi\) is the unique solution of the exterior Dirichlet boundary value problem

\[-\Delta \phi(x) = 0 \quad \text{for} \quad x \in \Omega^c, \quad \phi(x) = 1 \quad \text{for} \quad x \in \Gamma, \quad \phi(x) = \epsilon'(|x|^{-1}) \quad \text{as} \quad |x| \to \infty.\]

We assume that the boundary \(\Gamma = \partial \Omega\) has only one connected component. The variational formulation (13) of the transmission problem (10)–(12) is therefore not uniquely solvable. Hence, we introduce the gauging condition

\[\int_\Gamma E(x) \cdot n_x ds_x = 0,\]  

(14)

which corresponds to the conservation of charge. We define

\[\mathcal{Y} = \left\{ E \in \mathcal{H}(\text{curl} \mathbb{R}^3) : \text{div} E(x) = 0 \quad \text{for} \quad x \in \Omega^c, \quad \int_\Gamma E(x) \cdot n_x ds_x = 0 \right\}.\]

The variational problem (13) then admits a unique solution \(E_3 \in \mathcal{Y}\), see [11, 12].

3. A reduced model

The solution of the forward problem using the eddy current model as described in the previous section is computationally rather expensive. Since in most solution algorithms for the inverse problem the forward problem has to be solved quite often, we are interested in a simplified model which also allows a more efficient solution of the forward problem. For this we write the transmission problem (10)–(12) in terms of the \(A-\phi\) formulation [13]. Since \(B\) is divergence-free, we can represent the magnetic flux density \(B\) as the curl of a magnetic vector potential \(A\),

\[B(x) = \mu_0 \mathbf{H}(x) = \text{curl} \mathbf{A}(x) \quad \text{for} \quad x \in \mathbb{R}^3.\]

From

\[\text{curl} E(x) = -i\omega \mu_0 \mathbf{H}(x) = -i\omega \text{curl} \mathbf{A}(x)\]

we conclude the existence of a scalar potential \(\phi\) satisfying

\[E(x) + io \mathbf{A}(x) = -\nabla \phi(x) \quad \text{for} \quad x \in \mathbb{R}^3,\]

where \(\phi\) is uniquely determined by the Coulomb gauge

\[\text{div} \mathbf{A}(x) = 0 \quad \text{for} \quad x \in \mathbb{R}^3.\]  

(15)
By using the decomposition (8) we can write the primary field \( \mathbf{E}_p \) as

\[
\mathbf{E}_p(x) = -i\omega \mathbf{A}_p(x) \quad \text{for} \quad x \in \mathbb{R}^3,
\]

while for the secondary field \( \mathbf{E}_s \) we obtain

\[
\mathbf{E}_s(x) = -i\omega \mathbf{A}_s(x) - \nabla \psi(x) \quad \text{for} \quad x \in \mathbb{R}^3.
\]

Note that

\[
\mathbf{A}_p(x) = \frac{\mu_0}{4\pi} \int_{\mathbb{R}^3} \mathbf{j}(y) \frac{\mathbf{x} - \mathbf{y}}{|\mathbf{x} - \mathbf{y}|} \, dy \quad \text{for} \quad x \in \mathbb{R}^3.
\]

is a solution of the partial differential equations

\[
\nabla \times \frac{1}{\mu_0} \nabla \times \mathbf{A}_p(x) = \mathbf{j}(x), \quad \nabla \cdot \mathbf{A}_p(x) = 0 \quad \text{for} \quad x \in \mathbb{R}^3.
\] (16)

Now we can rewrite the eddy current model (3)–(6) for \( x \in \mathbb{R}^3 \) as

\[
\nabla \times \frac{1}{\mu_0} \nabla \times \mathbf{A}_i(x) + \kappa(x)[i\omega \mathbf{A}_s(x) + \nabla \psi(x)] = -i\omega \kappa(x) \mathbf{A}_p(x),
\]

\[
\nabla \cdot \mathbf{A}_i(x) = 0.
\] (17)

(18)

When applying the divergence operator to Equation (17), this gives

\[
-\nabla \cdot [\kappa(x)(i\omega \mathbf{A}_s(x) + \nabla \psi(x))] = i\omega \nabla \cdot [\kappa(x) \mathbf{A}_p(x)] \quad \text{for} \quad x \in \Omega.
\] (19)

In addition, we rewrite the transmission boundary condition (7) in terms of \( \mathbf{A} \) and \( \psi \) and obtain

\[
\kappa(x)[i\omega \mathbf{A}_s(x) + \mathbf{A}_p(x)] + \nabla \psi(x) \cdot \mathbf{n}_x = 0 \quad \text{for} \quad x \in \Gamma.
\] (20)

In the parameter range of MIT, numerical examples \([14]\) indicate that \( \mathbf{A}_s \) is very small compared to \( \nabla \psi \). Therefore, we neglect \( \mathbf{A}_s \) in (19) and (20), i.e. we finally conclude the Neumann boundary value problem

\[
-\nabla \cdot [\kappa(x) \nabla \tilde{\psi}(x)] = i\omega \nabla \cdot [\kappa(x) \mathbf{A}_p(x)] \quad \text{for} \quad x \in \Omega \quad \text{(21)}
\]

\[
\kappa(x) \frac{\partial}{\partial n_x} \tilde{\psi}(x) = -i\omega \kappa(x) \mathbf{A}_p(x) \cdot \mathbf{n}_x \quad \text{for} \quad x \in \Gamma \quad \text{(22)}
\]

where \( \tilde{\psi} \) now denotes the potential in the reduced model. Since \( \tilde{\psi} \) is not uniquely determined by the Neumann boundary value problem (21) and (22), we introduce the scaling condition

\[
\int_{\Gamma} \tilde{\psi}(x) \, ds_x = 0.
\] (23)

Moreover, by neglecting \( \mathbf{A}_s \) in (17) we obtain

\[
\nabla \times \frac{1}{\mu_0} \nabla \times \tilde{\mathbf{A}}_i(x) = -\kappa(x)[i\omega \mathbf{A}_p(x) + \nabla \tilde{\psi}(x)], \quad \nabla \cdot \tilde{\mathbf{A}}_i(x) = 0 \quad \text{for} \quad x \in \mathbb{R}^3,
\]

i.e.

\[
-\Delta \tilde{\mathbf{A}}_i(x) = -\mu_0 \kappa(x)[i\omega \mathbf{A}_p(x) + \nabla \tilde{\psi}(x)] \quad \text{for} \quad x \in \mathbb{R}^3.
\]

Hence, we conclude

\[
\tilde{\mathbf{A}}_i(x) = -\frac{\mu_0}{4\pi} \int_{\Omega} \kappa(y) \frac{i\omega \mathbf{A}_p(y) + \nabla \tilde{\psi}(y)}{|\mathbf{x} - \mathbf{y}|} \, dy \quad \text{for} \quad x \in \mathbb{R}^3.
\] (24)

The electric field can finally be obtained by

\[
\tilde{\mathbf{E}}_i(x) = -i\omega \tilde{\mathbf{A}}_i(x) - \nabla \tilde{\psi}(x) \quad \text{for} \quad x \in \mathbb{R}^3.
\] (25)

This means that the solution of the full eddy current model reduces to the solution of a Neumann boundary value problem for the Laplace equation, and the evaluation of a Newton potential. Both models are summarized in Table I.
The assertion then follows from Schmidt’s inequality, i.e.

\[
\mathbf{H} \text{ence we can write }
\]

In particular, we have

\[
\text{Lemma 3.1}
\]

\[
\int_{\Omega} \left| \nabla \cdot \mathbf{E}_1(x) \right|^2 \, dx = 0 \quad \text{for } x \in \mathbb{R}^3.
\]

Eddy current model

\[
\mathbf{E}_p(x) = -i\omega \int_{\Omega} \frac{\partial y}{|y-x|} \, dy \quad \text{for } x \in \mathbb{R}^3,
\]

\[
\nabla \times \mathbf{E}_p(x) + i\omega \mathbf{A}_p(x) = -i\omega \mathbf{E}_p(x) \quad \text{for } x \in \Omega,
\]

\[
\nabla \cdot (\mu(x) \mathbf{E}_p(x) + \mathbf{E}_p(x)) = 0 \quad \text{for } x \in \Omega,
\]

\[
\nabla \cdot \mathbf{E}_p(x) = 0 \quad \text{for } x \in \Omega^c.
\]

It remains to estimate the error when considering the reduced model instead of the eddy current model, see also [15]. In particular we have to consider the differences \( \phi - \tilde{\phi} \) and \( \mathbf{A}_s - \mathbf{A}_p \), respectively. For this, we first introduce the Newton potential operator

\[
(N_0 u)(x) = \frac{1}{4\pi} \int_{\Omega} \frac{u(y)}{|x-y|} \, dy \quad \text{for } x \in \Omega.
\]

In the case of a vector-valued function \( u \) we consider the Newton potential \( N_0 u \) component-wise.

**Lemma 3.1**

Assume \( \Omega \subset B_1(0) \). The Newton potential operator \( N_0 : L^2(\Omega) \to L^2(\Omega) \) is bounded satisfying

\[
\|N_0\| \leq \sup_{0 \neq u \in L^2(\Omega)} \frac{\|N_0 u\|_{L^2(\Omega)}}{\|u\|_{L^2(\Omega)}} \leq \frac{1}{\sqrt{3}}.
\]

**Proof**

By using the Hölder inequality we have

\[
\|N_0 u\|_{L^2(\Omega)}^2 = \int_{\Omega} \left| \frac{1}{4\pi} \int_{\Omega} \frac{u(y)}{|x-y|} \, dy \right|^2 dx \leq \frac{1}{(4\pi)^2} \|u\|_{L^2(\Omega)}^2 \int_{\Omega} \int_{\Omega} \frac{1}{|x-y|^2} \, dy \, dx.
\]

The assertion then follows from Schmidt’s inequality, i.e.

\[
\int_{\Omega} \frac{1}{|x-y|^2} \, dy \leq \int_{B(0)} \frac{1}{|x-y|^2} \, dy \leq 4\pi r \quad \text{for } x \in \mathbb{R}^3,
\]

In particular, we have

\[
\int_{\Omega} \int_{\Omega} \frac{1}{|x-y|^2} \, dy \, dx \leq \int_{B(0)} 4\pi r \, dx \leq \int_{B(0)} 4\pi r dx = (4\pi)^2 \frac{4}{3},
\]

which concludes the proof. \( \square \)

Let \( \mathbf{A}_s \) be the solution of the eddy current model (17)–(18), in particular by using (18) we can rewrite (17) as

\[
-\Delta \mathbf{A}_s(x) = -\mu_0 \kappa(x) [i\omega \mathbf{A}_s(x) + i\omega \mathbf{A}_p(x) + \nabla \phi(x)] \quad \text{for } x \in \mathbb{R}^3.
\]

Hence we can write \( \mathbf{A}_s \) as the Newton potential

\[
\mathbf{A}_s(x) = -\mu_0 N_0 \kappa(x) [i\omega \mathbf{A}_s + i\omega \mathbf{A}_p + \nabla \phi].
\]

Correspondingly, we have

\[
\tilde{\mathbf{A}}_s(x) = -\mu_0 N_0 \kappa(x) [i\omega \mathbf{A}_p + \nabla \tilde{\phi}]
\]

where \( \nabla \tilde{\phi} \) is chosen such that

\[
\text{div} \tilde{\mathbf{A}}_s(x) = 0 \quad \text{for } x \in \mathbb{R}^3.
\]
We therefore conclude
\[ A_s - \tilde{A}_s = -\mu_0 N_0 (\kappa (i \omega A_s + \nabla \phi^\delta)), \quad \phi^\delta := \phi - \tilde{\phi}. \] (30)

**Theorem 3.2**
Let us define
\[ \kappa_{\min} := \sqrt{\inf_{x \in \Omega} \Re (\kappa(x))^2 + \inf_{x \in \Omega} \Im (\kappa(x))^2}, \quad \kappa_{\max} := \sup_{x \in \Omega} |\kappa(x)| \]
and
\[ q := \mu_0 \kappa_{\max} \left( 1 + \frac{\kappa_{\max}}{\kappa_{\min}} \right). \]

Let \( \phi, \tilde{\phi} \in H^1(\Omega) \) be the weak solutions of the Neumann-type boundary value problems (19)–(20) and (21)–(22), respectively. Then there holds the error estimate
\[ \| \nabla \phi^\delta \|_{L^2(\Omega)} \leq \frac{\kappa_{\max}}{\kappa_{\min}} \| A_s \|_{L^2(\Omega)}. \] (31)

If we assume \( q < 1 \), then there holds
\[ \| A_s \|_{L^2(\Omega)} \leq \frac{q}{1 - q} \| A_p \|_{L^2(\Omega)} \] (32)
and
\[ \| A_s - \tilde{A}_s \|_{L^2(\Omega)} \leq \frac{q^2}{1 - q} \| A_p \|_{L^2(\Omega)}. \] (33)

**Proof**
From (19) and (21) we first conclude that \( \phi^\delta := \phi - \tilde{\phi} \) is a solution of the partial differential equation
\[ - \nabla \cdot (\kappa(x) \nabla \phi^\delta(x)) = i \omega \nabla \cdot (\kappa(x) A_s(x)) \quad \text{for } x \in \Omega \]
with the Neumann boundary condition
\[ \kappa(x) \left[ \frac{\partial}{\partial n_x} \phi^\delta(x) + i \omega A_s(x) \cdot n_x \right] = 0 \quad \text{for } x \in \Gamma. \]

Hence, for \( \psi \in H^1(\Omega) \) the weak formulation of the above Neumann boundary value problem reads as
\[
\int_{\Omega} \kappa(x) \nabla \phi^\delta(x) \cdot \nabla \psi(x) \, dx = i \omega \int_{\Omega} \nabla \cdot [\kappa(x) A_s(x)] \psi(x) \, dx + \int_{\Gamma} \kappa(x) \frac{\partial}{\partial n_x} \phi^\delta(x) \psi(x) \, ds_x
= \int_{\Gamma} \kappa(x) \left[ i \omega A_s(x) \cdot n_x + \frac{\partial}{\partial n_x} \phi^\delta(x) \right] \psi(x) \, ds_x - i \omega \int_{\Omega} \kappa(x) A_s(x) \cdot \nabla \psi(x) \, dx
= -i \omega \int_{\Omega} \kappa(x) A_s(x) \cdot \nabla \psi(x) \, dx.
\]

For \( \psi = \phi^\delta \) we therefore have
\[
\int_{\Omega} \kappa(x) |\nabla \phi^\delta(x)|^2 \, dx = -i \omega \int_{\Omega} \kappa(x) A_s(x) \cdot \nabla \phi^\delta(x) \, dx
\]
from which (31) follows, i.e.
\[ \| \nabla \phi^\delta \|_{L^2(\Omega)} \leq \frac{\kappa_{\max}}{\kappa_{\min}} \| A_s \|_{L^2(\Omega)}. \]

Moreover, with (27) and by using Lemma 3.1 we further have
\[
\| A_s \|_{L^2(\Omega)} = \mu_0 N_0 (\kappa (i \omega A_s + \nabla \phi)) \| A_s \|_{L^2(\Omega)}
\leq \mu_0 \kappa_{\max} \frac{r^2}{\sqrt{3}} \| i \omega A_s + \nabla \phi \|_{L^2(\Omega)}
\leq \mu_0 \kappa_{\max} \frac{r^2}{\sqrt{3}} (\| A_s \|_{L^2(\Omega)} + \| A_p \|_{L^2(\Omega)} + \| \nabla \phi \|_{L^2(\Omega)}). \] (34)
The variational formulation of the Robin type boundary value problem (19) and (20) reads, for \( \psi \in \mathcal{H}^1(\Omega) \),

\[
\int_{\Omega} \kappa(x) \nabla \phi(x) \cdot \nabla \psi(x) \, dx = i\omega \int_{\Omega} \nabla \cdot [ \kappa(x) (A_p(x) + A_s(x))] \psi(x) \, dx + \int_{\Gamma} \kappa(x) \frac{\partial}{\partial n_x} \phi(x) \psi(x) \, ds_x
\]

\[
= \int_{\Omega} \kappa(x) \left[ i\omega (A_p(x) + A_s(x)) \cdot n_x + \frac{\partial}{\partial n_x} \phi(x) \right] \psi(x) \, dx - i\omega \int_{\Omega} \kappa(x) (A_p(x) + A_s(x)) \cdot \nabla \psi(x) \, dx
\]

\[
= -i\omega \int_{\Omega} \kappa(x) (A_p(x) + A_s(x)) \cdot \nabla \psi(x) \, dx.
\]

For \( \psi = \phi \) we therefore have

\[
\int_{\Omega} \kappa(x) |\nabla \phi(x)|^2 \, dx = -i\omega \int_{\Omega} \kappa(x) (A_p(x) + A_s(x)) \cdot \nabla \phi(x) \, dx,
\]

from which the estimate

\[
\| \nabla \phi \|_{L_2(\Omega)} \leq \frac{K_{\text{max}}}{K_{\text{min}} \omega} \| A_p + A_s \|_{L_2(\Omega)}
\]

follows. From (34) we therefore conclude

\[
\| A_p \|_{L_2(\Omega)} \leq \mu_0K_{\text{max}} \frac{\rho^2}{\sqrt{3}} \left( 1 + \frac{K_{\text{max}}}{K_{\text{min}}} \right) \left( \| A_s \|_{L_2(\Omega)} + \| A_p \|_{L_2(\Omega)} \right),
\]

which immediately results in the estimate (32) when we assume \( q < 1 \).

Finally, by using (30) and Lemma 3.1 we have

\[
\| A_s - \tilde{A}_s \|_{L_2(\Omega)} = \mu_0 \| \kappa (i\omega (A_s + \nabla \phi^0)) \|_{L_2(\Omega)}
\]

\[
\leq \mu_0 \frac{\rho^2}{\sqrt{3}} \| \kappa (i\omega A_s + \nabla \phi^0) \|_{L_2(\Omega)}
\]

\[
\leq \mu_0K_{\text{max}} \frac{\rho^2}{\sqrt{3}} (\| A_s \|_{L_2(\Omega)} + \| \nabla \phi^0 \|_{L_2(\Omega)})
\]

\[
\leq \mu_0K_{\text{max}} \frac{\rho^2}{\sqrt{3}} \left( 1 + \frac{K_{\text{max}}}{K_{\text{min}}} \right) \| A_s \|_{L_2(\Omega)} = q \| A_s \|_{L_2(\Omega)}
\]

due to (31). Now, (33) follows from (32).

\[\square\]

Remark 3.1
As an example we may consider a test problem with the following parameters:

\[0.1 \leq \kappa(x) \leq 1 \quad \text{for} \quad x \in \Omega, \quad \Omega \subset B_{0.1}(0), \quad \omega = 10^5.\]

In this case, we have

\[q = 7.98 \times 10^{-3}, \quad \frac{q^2}{1-q} = 6.42 \times 10^{-5}, \quad \| A_p \|_{L_2(\Omega)} \approx 3.609 \times 10^{-6},\]

where the last result was obtained by using some finite element discretization.

Corollary 3.3
In addition we have an estimate for the error in an arbitrary point \( x \in \mathbb{R}^3 \)

\[
| A_s(x) - \tilde{A}_s(x) | \leq \frac{q^2}{1-q} \| A_p \|_{L_2(B_0(0))}.
\]

(35)
Proof
By using (30) we have, for $x \in \Omega$,

$$|A_s(x) - \overline{A}_s(x)| = \frac{\mu_0}{4\pi} \left| \int_{\Omega} \kappa(x) \frac{i\omega A_s(y) + \nabla \phi^\delta(y)}{|x-y|} \, dy \right|$$

$$\leq \frac{\mu_0}{4\pi} \kappa_{\text{max}} \sqrt{4\pi \rho \kappa(x)} \left( \int_{\Omega} \frac{1}{|x-y|^2} \, dy \right)^{1/2}$$

$$\leq \frac{\mu_0}{4\pi} \kappa_{\text{max}} \sqrt{4\pi \rho \kappa(x)} \left( \int_{\Omega} \frac{1}{|x-y|^2} \, dy \right)^{1/2}$$

$$\leq \frac{\mu_0}{4\pi} \kappa_{\text{max}} \sqrt{4\pi \rho \kappa(x)} \left( \int_{\Omega} \frac{1}{|x-y|^2} \, dy \right)^{1/2}$$

$$= \frac{\mu_0 \kappa_{\text{max}}}{4\pi} \sqrt{4\pi \rho \kappa(x)} \left( \int_{\Omega} \frac{1}{|x-y|^2} \, dy \right)^{1/2}$$

$$= \frac{\mu_0 \kappa_{\text{max}}}{4\pi} \sqrt{4\pi \rho \kappa(x)} \left( \int_{\Omega} \frac{1}{|x-y|^2} \, dy \right)^{1/2}$$

The quantity, which is measured in MIT is the voltage in the receiver coil $\mathcal{V}$, i.e.

$$\mathcal{V} := \int_{\mathcal{V}} B_s(x) \cdot n_x \, ds_x.$$ 

Hence, we need to evaluate

$$B_s(x) = \nabla \times A_s(x) = \frac{\mu_0}{4\pi} \int_{\Omega} \kappa(y) \nabla_x \frac{1}{|x-y|} \times [i\omega A_p(y) + \nabla_y \phi(y)] \, dy \quad \text{for} \ x \in \mathcal{V}. \quad (36)$$

By using integration by parts, and by using

$$\nabla_x \frac{1}{|x-y|} = -\nabla_y \frac{1}{|x-y|}$$

the volume integral in (36) can be reformulated as

$$B_s(x) = \frac{\mu_0}{4\pi} \sum_{k=1}^{N} \kappa_k \left( i\omega \int_{\Omega} \nabla_x \frac{1}{|x-y|} \times A_p(y) \, dy - \int_{\Omega} \nabla_x \frac{1}{|x-y|} \times \nabla_y \phi(y) \, dy \right)$$

$$= \frac{\mu_0}{4\pi} \sum_{k=1}^{N} \kappa_k \left( i\omega \int_{\Omega} \nabla_x \frac{1}{|x-y|} \times A_p(y) \, dy - \int_{\Omega} \nabla_y \phi(y) \times n_y \, ds_y \right),$$

where $\nabla_y \phi(y) \times n_y$ for $y \in \Gamma_k$ denotes the surface curl of the function $\phi$.

4. A boundary element method for the reduced model

In this section we derive a boundary element formulation for the reduced model as described in the previous section. The variational formulation of the Neumann boundary value problem (21), (22) and (23) is to find $\phi \in H^1(\Omega)$ such that

$$\int_{\Omega} \kappa(x) \nabla \phi(x) \cdot \nabla \psi(x) \, dx + \int_{\Gamma} \phi(x) \, ds_x \int_{\Gamma} \psi(x) \, ds_x = i\omega \int_{\Omega} \kappa(x) A_p(x) \cdot \nabla \psi(x) \, dx \quad (37)$$

for all $\psi \in H^1(\Omega)$. For a piecewise constant conductivity $\kappa(x)$ we consider a non-overlapping domain decomposition

$$\overline{\Omega} = \bigcup_{k=1}^{P} \overline{\Omega}_k, \quad \Omega_k \cap \Omega_{k'} = \emptyset \quad \text{for} \ k \neq k', \quad \Gamma = \bigcup_{k=1}^{P} \Gamma_k, \quad \Gamma_k = \partial \Omega_k, \quad \kappa(x) = \kappa_k \quad \text{for} \ x \in \Omega_k.$$ 

Instead of the global Neumann boundary value problem (21) and (22) we now consider the local boundary value problems, by using (16)

$$-\kappa_k A \phi|_{\Omega_k} = 0 \quad \text{for} \ x \in \Omega_k, \quad \kappa_k \frac{\partial}{\partial n_k} \phi(x) = -i\omega \kappa_k A_p(x) \cdot n_x \quad \text{for} \ x \in \Gamma_k \cap \Gamma \quad (38)$$

together with the transmission boundary conditions, see (7),

$$
\kappa_k \frac{\partial}{\partial n_k} \phi(x) + \kappa \frac{\partial}{\partial n_\ell} \phi(x) = -i\omega \kappa \kappa_k A_p(x) \cdot n_k - i\omega \kappa \kappa_\ell A_p(x) \cdot n_\ell \quad \text{for} \ x \in \Gamma_k \cap \Gamma_\ell.
$$
Thus, we can rewrite the variational formulation (37) as
\[
\sum_{k=1}^{p} \int_{\Gamma_k} \kappa_k \frac{\partial}{\partial n_k} \tilde{\phi}(x) \psi(x) \, ds_x + \int_{\Gamma} \tilde{\phi}(x) \psi(x) \, ds_x = \sum_{k=1}^{p} i\omega \int_{\Gamma_k} \kappa_k [A_p(x) \cdot n_k] \psi(x) \, ds_x.
\]
For the solution of the local partial differential equation in (38) we use the local Dirichlet to Neumann map
\[
\frac{\partial}{\partial n_k} \tilde{\phi}(x) = (S_k \tilde{\phi})(x) \quad \text{for } x \in \Gamma_k = \partial \Omega_k,
\]
where \( S_k : H^{1/2}(\Gamma_k) \to H^{-1/2}(\Gamma_k) \) is the associated Steklov–Poincaré operator [16]. Let \( H^{1/2}(\Gamma) := H^1(\Omega)|_{\Gamma} \) be the skeleton trace space of \( H^1(\Omega) \). We then have to solve a variational problem to find \( \tilde{\phi} \in H^{1/2}(\Gamma) \) such that
\[
\sum_{k=1}^{p} \kappa_k \int_{\Gamma_k} (S_k \tilde{\phi})(x) \psi(x) \, ds_x + \int_{\Gamma} \tilde{\phi}(x) \psi(x) \, ds_x = \sum_{k=1}^{p} i\omega \int_{\Gamma_k} \kappa_k [A_p(x) \cdot n_k] \psi(x) \, ds_x
\]
is satisfied for all \( \psi \in H^{1/2}(\Gamma) \). Since the bilinear form in the variational formulation (39) is bounded and \( H^{1/2}(\Gamma) \)-elliptic, see, e.g. [17], unique solvability of the variational formulation (39) follows.

To describe the application of the local Steklov–Poincaré operators which are involved in the variational formulation (39) we use the symmetric boundary integral operator representations
\[
(S_k \tilde{\phi}|_{\Gamma_k})(x) = \left[ D_k + \left( \frac{1}{2} + K'_k \right) V^{-1}_k \left( \frac{1}{2} + K_k \right) \right] \tilde{\phi}|_{\Gamma_k}(x) \quad \text{for } x \in \Gamma_k,
\]
where
\[
(V_k w)(x) = \frac{1}{4\pi} \int_{\Gamma_k} \frac{1}{|x-y|} w(y) \, ds_y \quad \text{for } x \in \Gamma_k
\]
is the single layer integral operator,
\[
(K_k \psi)(x) = \frac{1}{4\pi} \int_{\Gamma_k} \frac{\partial}{\partial n_k} \frac{1}{|x-y|} \psi(y) \, ds_y \quad \text{for } x \in \Gamma_k
\]
is the double layer integral operator, and
\[
(D_k \psi)(x) = -\frac{1}{4\pi} \frac{\partial}{\partial n_k} \int_{\Gamma_k} \frac{\partial}{\partial n_k} \frac{1}{|x-y|} \psi(y) \, ds_y \quad \text{for } x \in \Gamma_k
\]
is the so-called hypersingular boundary integral operator. The mapping properties of all boundary integral operators and therefore of the local Steklov–Poincaré operators \( S_k \) are well known, see, e.g. [18–21].

For a symmetric boundary element discretization of the variational formulation (39) we introduce a sequence of admissible boundary element meshes \( \Gamma_{S,h} \) with a globally quasi-uniform mesh size \( h \). Let \( S^1_k(\Gamma) = S^1_k(\Gamma) \cap \Gamma_k \) be the associated boundary element space of piecewise linear continuous basis functions \( \varphi_i \). By \( S^1_k(\Gamma_k) = S^1_k(\Gamma_k) \cap \Gamma_k \) we denote the localized boundary element space of local basis functions \( \varphi_{k,i} \), and by \( \tilde{\varphi}_k = \tilde{A}_k \tilde{\phi} \) we describe the localization of the global degrees of freedom. The symmetric boundary element approximation of the variational problem (39) results in the linear system, see, e.g. [16],
\[
\sum_{k=1}^{p} \kappa_k A^T_k S_k h A_k \phi = -i\omega \sum_{k=1}^{p} \kappa_k A^T_k \ell_k,
\]
where
\[
S_{k,h} = D_{k,h} + \left( \frac{1}{2} M^T_{k,h} + K^T_{k,h} \right) V_{k,h}^{-1} \left( \frac{1}{2} M_{k,h} + K_{k,h} \right)
\]
are the discrete Steklov–Poincaré operators. Note that
\[
D_{k,h}[i,j] = \langle D_k \varphi_{k,i}, \varphi_{k,j} \rangle_{\Gamma_k},
\]
\[
V_{k,h}[k,m] = \langle V_k \psi_{k,m}, \psi_{k,k} \rangle_{\Gamma_k},
\]
\[
K_{k,h}[k,l] = \langle K_k \varphi_{k,j}, \psi_{k,l} \rangle_{\Gamma_k},
\]
\[
M_{k,h}[k,l] = \langle \varphi_{k,i}, \psi_{k,l} \rangle_{\Gamma_k}
\]
are local boundary element matrices, and $S_p^0(\Gamma_k)$ are local boundary element spaces of, e.g. piece-wise constant basis functions $\psi_k$. Moreover, the right-hand side in (41) is given locally as

$$f_{kj} = \int_{\Gamma_k} [A_k(x) \cdot n_k] \phi_{kj}(x) \, ds_x.$$ 

The stability and error analysis of the symmetric boundary element discretization of the variational problem (39) is well established, see, e.g. [16], and the references given therein.

5. Numerical results

As conducting domain we first consider the cylinder

$$\Omega = \{x \in \mathbb{R}^3, x_1^2 + x_2^2 < 0.1, 0 < x_3 < 0.2\},$$

where the transmitting coil is modeled as a current loop of radius 0.04 which is centered at $(-0.14, 0, 0.1)^T$, see Figure 2. The vector normal to the current loop points into the direction of the $x_1$-axis, i.e., $n_x = (1, 0, 0)^T$. Inside the cylinder we place a ball with radius $r = 0.02$, whose center lies in the point $(-0.06, 0.01)^T$.

The background conductivity of the cylinder is $\kappa = 0.1$, and the conductivity of the inscribed ball is $\kappa_{\text{inc}}$. Figure 2 shows the magnitude of the electric field $|n \times (E \times n)|$ for $\kappa_{\text{inc}} = 0.1$. In Figure 3 we give a comparison of the reduced model with the full

eddy current model. For this we plot the real and imaginary parts of the normal component of the magnetic field \( \mathbf{B}(x) \cdot n_x \) along a circle around the cylinder for the frequency \( f = 100 \text{kHz} \), and for varying conductivities \( \kappa_{\text{inc}} \in \{0.1, 1, 10\} \). For the reduced model \( \mathbf{B}(x) \cdot n_x \) was computed by using the boundary element approach as described in the previous section. The solution of the full eddy current problem was computed by using the Finite Element software packages Netgen \[22\] and NGSolve.‡

For the reduced model we have \( \Re(\mathbf{B}(x) \cdot n_x) = 0 \), while for the full eddy current model \( \Re(\mathbf{B}(x) \cdot n_x) \) is comparable small. For the imaginary part we obtain a very good coincidence between the solution of the reduced and of the full model. Indeed, in Figure 4 we give a plot of the error and of the relative error in \( x = (-0.141, -0.141, 0.15)^\top \) between the normal magnetic field computed with the full eddy current model and the reduced model in the case \( \kappa_{\text{inc}} = 0.1 \), and for a frequency range from 100 kHz up to 1 GHz.

Based on the above results we conclude that the reduced model describes an appropriate approximation of the full eddy current model as used in MIT models.

In a second example we consider the model of a human thorax with two lungs, see Figure 5. The volume mesh consists of 83 514 volume elements and 15 641 volume nodes, while the boundary element mesh consists of 13 076 boundary elements.

and 7548 boundary nodes. The background conductivity of the thorax was set to the conductivity of a muscle at 100 kHz, i.e. \( \kappa_{\text{muscle}} = 0.36185 \, \text{s/m} \), while the conductivity of the lungs is \( \kappa_{\text{lung}} = 0.27165 \, \text{s/m} \), see [23]. The center of the transmitting coil was placed in the point \((0, -0.2, 0)^T\), the normal vector of the coil is given by \((0, 1, 0)^T\), and its radius is 0.05. In Figure 5 we plot the magnitude of the tangential trace of the electric field, i.e. \(|n \times (E \times n)|\). The field lines of the primary magnetic field \( B_p \) of the secondary magnetic field \( B_s \) are given in Figure 6.

6. Conclusions and outlook

In this paper we derived two models which describe the forward problem of MIT, an eddy current problem and a reduced model. We proved estimates for the error between the reduced and the eddy current model, and we formulated a boundary element method for the reduced model. Numerical examples show that the reduced model is a good approximation for the eddy current model in the parameter range of MIT.

To be able to reconstruct the complex conductivity distribution inside the human body with MIT, an inverse problem has to be solved. For the reconstruction of the location and of the shape of organs, a shape reconstruction approach in combination with a level set method can be used. For such an approach, the application of boundary element methods seems to be advantageous, since in every step of the level set method only the boundary has to be remeshed. The solution of the inverse problem demands a very fast solution of the forward problem on meshes with a high number of degrees of freedom. To establish a fast solver for the forward problem, fast boundary element methods may be employed such as the fast multipole method or hierarchical matrices.

Acknowledgements
