Abstract—Place bisimilarity $\sim_p$ is a behavioral equivalence for finite Petri nets, originally proposed in [2], that, differently from all the other behavioral relations proposed so far, is not defined over the markings of a finite net, rather over its places, which are finitely many. Place bisimilarity $\sim_p$ was claimed decidable in [2], but its decidability was not really proved. We show that it is possible to decide $\sim_p$ with a simple algorithm, which essentially scans all the place relations (which are finitely many) to check whether they are place bisimulations. We also show that $\sim_p$ does respect the intended causal semantics of Petri nets, as it is finer than causal-net bisimilarity [19]. Moreover, we propose a slightly coarser variant, we call d-place bisimilarity $\sim_d$, that we conjecture to be the coarsest equivalence, fully respecting causality and branching time (as it is finer than fully-concurrent bisimilarity [5]), to be decidable on finite Petri nets. Finally, two even coarser variants are discussed, namely i-place and i-d-place bisimilarities, which are still decidable, do preserve the concurrent behavior of Petri nets, but do not respect causality. These results open the way towards formal verification (by equivalence checking) of distributed systems modeled by finite Petri nets.

1 INTRODUCTION

There is widespread agreement that a very natural equivalence relation for sequential, nondeterministic systems is bisimulation equivalence [33], [29], defined over the semantic model of labeled transition systems [26] (LTSs, for short). Bisimulation equivalence, which fully respects the branching structure of systems, is defined coinductively, has a nice fixpoint characterization, is easily decidable for finite-state LTSs, even decidable on some classes of infinite state systems.

When considering distributed systems, one very natural semantic model is given by finite Petri nets (see, e.g., [34], [36], [16]), in particular finite Place/Transition Petri nets [9] (P/T nets, for short), a distributed model of computation that can represent a class of distributed systems where the number of sequential components can grow unboundedly. Petri nets have been extensively used for the modeling and analysis of real distributed systems (see, e.g., [38], [37] and the references therein). However, (almost) all the behavioral equivalence relations that were defined on finite P/T nets (e.g., in the spectrum ranging from interleaving bisimilarity to fully concurrent bisimilarity [5]) are relations over the global states of the net, called markings (possibly decorated with some history information), which are usually infinitely many, and so, not surprisingly, these equivalence relations are all undecidable, as observed by Jančar [23] and Esparza [10]. Indeed, by these observations, it seems impossible to algorithmically compare the behavior of finite P/T nets, in order to verify the correctness of a distributed system by computing a behavioral equivalence relation between its specification net and its implementation net, i.e., by means of equivalence checking, a well-known formal verification technique. We want to contradict this idea by showing that this is possible, at least in principle.

As a matter of fact, one relevant exception exists: place bisimilarity, originating from an idea by Olderog [31] (under the name of strong bisimilarity) and then refined by Autant, Belmesk and Schnoebelen [2], which is an equivalence over markings, based on relations over the finite set of net places, rather than over the (possibly infinite) set of net markings. This equivalence is very natural and intuitive: as a place can be interpreted as a sequential process type (and each token in this place as an instance of a sequential process of that type), a place bisimulation essentially states which kinds of sequential processes (composing the distributed system represented by the Petri net) are to be considered as equivalent.

Informally, a binary relation $R$ over the set $S$ of places is a place bisimulation if for all markings $m_1$ and $m_2$ which are \textit{bijectively} related via $R$ (denoted by $(m_1, m_2) \in R^\circ$, where $R^\circ$ is called the \textit{additive closure of $R$}), if $m_1$ can perform transition $t_1$, reaching marking $m'_1$, then $m_2$ can perform transition $t_2$, reaching marking $m_2$, such that the pre-sets of $t_1$ and $t_2$ are related by $R^\circ$ (i.e., $(t_1, t_2) \in R^\circ$), the label of $t_1$ and $t_2$ is the same, the post-sets of $t_1$ and $t_2$ are related by $R^\circ$ (i.e., $(t_1^*, t_2^*) \in R^\circ$), and also for the residual markings we have $(m_1 \ominus t_1, m_2 \ominus t_2) \in R^\circ$; and symmetrically if $m_2$ moves first. The fact that the post-sets of $t_1$ and $t_2$ are related by $R^\circ$ and $(m_1 \ominus t_1, m_2 \ominus t_2) \in R^\circ$ ensures that $(m'_1, m'_2) \in R^\circ$.

Two markings $m_1$ and $m_2$ are place bisimilar, denoted by $m_1 \sim_p m_2$, if a place bisimulation $R$ exists such that $(m_1, m_2) \in R^\circ$. Place bisimilarity does respect the expected causal behavior of Petri nets; as a matter of fact, we show that place bisimilarity is slightly finer than causal-net bisimilarity [19] (or, equivalently, \textit{structure preserving bisimilarity} [14]), in turn slightly finer than fully-concurrent bisimilarity [5] (or, equivalently, history-
preserving bisimilarity \cite{35,12,8}).

To be precise, in the original definition of place bisimulation in \cite{2}, the weaker condition \((m_1', m_2') \in R^\oplus\) was required instead of the stronger condition \((m_1 \oplus t_1, m_2 \oplus t_2) \in R^\oplus\) we propose. However, we will show in Section 4 that, according to the original one in \cite{2}, matched computations in the place bisimulation game may generate different causal nets \cite{15,3,14}, so that we think our definition is more natural, even if both variants define the same equivalence relation.

Place bisimilarity is an equivalence relation, but its definition is not coinductive because the union of place bisimulations may not be a place bisimulation; so, in general, there is not one single largest place bisimulation, rather many maximal place bisimulations. In fact, place bisimilarity is the relation on markings obtained by the union of the additive closure of each maximal place bisimulation. As a consequence, the classic algorithms for computing the coinductive bisimulation equivalence on LTSs \cite{24}, \cite{32} cannot be adapted to compute place bisimilarity.

Place bisimilarity \(\sim_p\) was claimed decidable in \cite{2} and a polynomial-time algorithm was presented in \cite{3} to this aim. To be precise, the algorithm in \cite{3} is tailored for \(i\)-place bisimilarity \(\sim_i\) (cf. Section 7), even if it is argued that this algorithm can be easily adapted for deciding also place bisimilarity \(\sim_p\). However, the (variant of) the algorithm in \cite{3} does not characterize \(\sim_p\), rather the subequivalence \(\sim_{p,q} \subseteq \sim_p\) corresponding to the only maximal place bisimulation which is also an equivalence relation; hence, the decidability of place bisimilarity was not proved.

The main contribution of this paper is to show that \(\sim_p\) is decidable for finite P/T nets, indeed. The proof idea is as follows. Note that a place relation \(R \subseteq S \times S\) is finite if the set \(S\) of places is finite; hence, there are finitely many place relations for a finite net. We can list all these place relations, say \(R_1, R_2, ... , R_n\). It is possible to decide whether a place relation \(R_i\) in this list is a place bisimulation by checking two finite conditions over a finite number of marking pairs: this is a non-obvious observation, as a place bisimulation requires that the place bisimulation game holds for the infinitely many pairs \((m_1, m_2)\) belonging to \(R_i^\oplus\). Hence, to decide whether \(m_1 \sim_p m_2\), it is enough to check, for \(i = 1, ..., n\), whether \(R_i\) is a place bisimulation and, in such a case, whether \((m_1, m_2) \in R_i^\oplus\).

Moreover, we propose a slightly coarser variant, we call \(d\)-place bisimilarity and denote by \(\sim_d\), that we conjecture to be the coarsest, sensible (i.e., fully respecting causality and branching time) equivalence to be decidable on finite P/T Petri nets (without silent moves). Essentially, a \(d\)-place bisimulation is a relation on the set whose elements are the places and the empty marking, which is considered as an additional dummy place. This weaker variant is still finer than \(\text{fully-concurrent bisimilarity} \sim_f\). The decidability proof of \(d\)-place bisimilarity \(\sim_d\) is very similar to that of place bisimilarity \(\sim_p\).

Finally, we recall the coarsest variant of place bisimilarity proposed in \cite{3}, namely \(i\)-place bisimilarity \(\sim_i\). An \(i\)-place bisimulation \(R\) is a relation such that \(R^\oplus\) is an interleaving bisimulation. We argue that \(i\)-place bisimilarity \(\sim_i\) is still decidable, by adapting the same proof technique we provided for deciding place bisimilarity \(\sim_p\). However, \(\sim_i\) is not fully satisfactory; even if it respects the branching time, it does not respect causality. As a last minor contribution, we propose an even coarser decidable variant, called \(i\)-place bisimilarity \(\sim_{id}\), that is the coarsest decidable equivalence defined so far on finite P/T Petri nets respecting the branching time (but not causality); nonetheless, we prove that \(\sim_{id}\) is finer than \(\text{step bisimilarity} \sim_s\) (originally proposed in \cite{30}) and so it preserves the concurrent behavior of nets.

Figure 1 summarizes the relations among the eight different behavioral equivalences we are studying in this paper, where the top element is the most discriminating one (namely, place bisimilarity \(\sim_p\)) and the bottom element is the coarsest one (namely, interleaving bisimilarity \(\sim_{id}\)). Note that the equivalences based on place relations (namely, place bisimilarity \(\sim_p\), \(d\)-place bisimilarity \(\sim_d\), \(i\)-place bisimilarity \(\sim_i\) and \(i\)-place bisimilarity \(\sim_{id}\)) are all decidable, while the other ones (namely, causal-net bisimilarity \(\sim_{cn}\), fully-concurrent bisimilarity \(\sim_f\), step bisimilarity \(\sim_s\) and interleaving bisimilarity \(\sim_{id}\)) are not.

The paper is organized as follows. Section 2 recalls the basic definitions about Petri nets, including their interleaving, concurrent and causal semantics. Section 3 deals with place bisimilarity, shows that it is an equivalence relation, that it is not coinductive, and, by means of examples, shows that \(\sim_p\) is different from \(\sim_{p,q}\), i.e., the only maximal place bisimulation which is also an equivalence relation (algorithmically characterized in \cite{3}). Section 4 proves that place bisimilarity implies causal-net bisimilarity and introduces an example showing that the original definition of place bisimulation in \cite{2} may not always fully respect causality. Section 5 proves that \(\sim_p\) is decidable and discusses that the two variant definitions of place bisimilarity characterize the same behavioral equivalence. Section 6 introduces the coarser \(d\)-place bisimilarity \(\sim_d\) and proves that it implies fully-concurrent bisimilarity and that it is still decidable. Section 7 recalls \(i\)-place bisimilarity from \cite{3}, introduces the newly proposed coarser variant \(i\)-place bisimilarity, shows that the latter implies step bisimilarity and hints that they are both decidable, too. Finally, Section 8 discusses the pros and cons of place bisimilarity, overviews related literature and hints some possible future research.

2 Petri Nets

Definition 1. (Multiset) Let \(\mathbb{N}\) be the set of natural numbers. A multiset over a finite set \(S\) is a function \(m: S \rightarrow \mathbb{N}\). The support set \(\text{dom}(m)\) of \(m\) is \(\{s \in S \mid m(s) \neq 0\}\). The set of all multisets over \(S\), denoted by \(\mathbb{M}(S)\), is ranged over by \(m\). We write \(s \in m\) if \(m(s) > 0\). The multiplicity of \(s\) in \(m\) is given by the number \(m(s)\). The size of \(m\), denoted by \(|m|\), is the number \(\sum_{s \in S} m(s)\), i.e., the total number of its elements. A multiset \(m\) such that

---

**Fig. 1. The diagram with the 8 behavioral equivalences studied in this paper.**
$dom(m) = \emptyset$ is called empty and is denoted by $\emptyset$. We write $m \subseteq m'$ if $m(s) \leq m'(s)$ for all $s \in S$.

**Multiset union** $\bigoplus$ is defined as follows: $(m \bigoplus m')(s) = m(s) + m'(s)$; it is commutative, associative and has $\emptyset$ as neutral element. **Multiset difference** $\bigominus$ is defined as follows: $(m_1 \bigominus m_2)(s) = \max\{m_1(s) - m_2(s), 0\}$. The scalar product of a number $j$ with $m$ is the multiset $j \cdot m$ defined as $(j \cdot m)(s) = j \cdot (m(s))$. By $s_i$ we also denote the multiset with $s_i$ as its only element. Hence, a multiset $m$ over $S = \{s_1, \ldots, s_n\}$ can be represented as $k_1 \cdot s_1 \bigoplus k_2 \cdot s_2 \bigoplus \ldots \bigoplus k_n \cdot s_n$, where $k_j = m(s_j) \geq 0$ for $j = 1, \ldots, n$.

**Definition 2. (Place/Transition Petri net)** A labeled Place/Transition Petri net ($\mathcal{P/T}$ net) is defined inductively as follows:

- $S$ is the finite set of places, ranged over by $s$ (possibly indexed),
- $A$ is the finite set of labels, ranged over by $\ell$ (possibly indexed), and
- $T \subseteq (\mathcal{A}(S) \setminus \{\emptyset\}) \times A \times \mathcal{A}(S)$ is the finite set of transitions, ranged over by $t$ (possibly indexed).

Given a transition $t = (m, \ell, m')$ we use the notation:

- $t^*$ to denote its pre-set $m$ (which cannot be an empty multiset) of tokens to be consumed;
- $l(t)$ for its label $\ell$, and
- $t^*$ to denote its post-set $m'$ of tokens to be produced.

Hence, transition $t$ can be represented as $t : l(t) \longrightarrow t^*$. We also define the function flow: $(S \times T) \cup (T \times S) \rightarrow \mathbb{N}$ as follows: for all $s \in S$, for all $t \in T$, flow$(s, t) = t^*(s)$ and flow$(t, s) = t^*_s(s)$. We will use $F$ to denote the flow relation $\{(x, y) \mid x, y \in S \cup T \land \text{flow}(x, y) > 0\}$. Finally, we define pre-sets and post-sets also for places as: $*s = \{t \in T \mid s \in t^*\}$ and $s^* = \{t \in T \mid s \in *t\}$.

Graphically, a place is represented by a little circle and a transition by a little box. These are connected by directed arcs, which may be labeled by a positive integer, called the weight, to denote the number of tokens consumed (when the arc goes from a place to the transition) or produced (when the arc goes from the transition to a place) by the execution of the transition; if the number is omitted, then the weight default value of the arc is 1.

**Definition 3. (Marking, $\mathcal{P/T}$ net system)** A multiset over $S$ is called a marking. Given a marking $m$ and a place $s$, we say that the place $s$ contains $m(s)$ tokens, graphically represented by $m(s)$ bullets inside place $s$. A $\mathcal{P/T}$ net system $N(m_0)$ is a tuple $(S, A, T, m_0)$, where $(S, A, T)$ is a $\mathcal{P/T}$ net and $m_0$ is a marking over $S$, called the initial marking. We also say that $N(m_0)$ is a marked net.

**2.2 Concurrent Semantics**

**Definition 4. (Enabling, firing sequence, transition sequence, reachable marking, safe net)** Given a $\mathcal{P/T}$ net $N = (S, A, T)$, a transition $t$ is enabled at $m$, denoted by $m[t]$, if $t^* \subseteq m$. The execution (or firing) of $t$ enabled at $m$ produces the marking $m' = (m \bigoplus t) \bigominus t^*$. This is written $m[t]m'$. A firing sequence starting at $m$ is defined inductively as follows:

- $m[\varepsilon]m'$ is a firing sequence (where $\varepsilon$ denotes an empty sequence of transitions) and
- if $m[\sigma]m'$ is a firing sequence and $m'[\tau]m''$, then $m[\sigma\tau]m''$ is a firing sequence.

The set of reachable markings from $m$ is $\{m' \mid \exists\sigma. m[\sigma]m'\}$. The $\mathcal{P/T}$ net system $N = (S, A, T, m_0)$ is safe if for each $m \in \{m_0\}$ and for all $s \in S$, we have that $m(s) \leq 1$.

Note that the reachable markings of a $\mathcal{P/T}$ net can be countably infinitely many even when the net is not bounded, i.e., when the number of tokens on some places can grow unboundedly.

Now we recall a simple behavioral equivalence on $\mathcal{P/T}$ nets, defined directly over the markings of the net, which compares two markings with respect to their sequential behavior.

**Definition 5. (Interleaving Bisimulation)** Let $N = (S, A, T)$ be a $\mathcal{P/T}$ net. An interleaving bisimulation is a relation $R \subseteq \mathcal{A}(S) \times \mathcal{A}(S)$ such that if $(m_1, m_2) \in R$ then

- $\forall t_1$ such that $m_1[t_1]m'_1, \exists t_2$ such that $m_2[t_2]m'_2$ with $l(t_1) = l(t_2)$ and $(m'_1, m'_2) \in R$,
- $\forall t_2$ such that $m_2[t_2]m'_2, \exists t_1$ such that $m_1[t_1]m'_1$ with $l(t_1) = l(t_2)$ and $(m'_1, m'_2) \in R$.

Two markings $m_1$ and $m_2$ are interleaving bisimilar, denoted by $m_1 \sim_{\text{int}} m_2$, if there exists an interleaving bisimulation $R$ such that $(m_1, m_2) \in R$.

Interleaving bisimilarity was proved undecidable in [23] for $\mathcal{P/T}$ nets having at least two unbounded places, with a proof based on the comparison of two sequential PT nets, where a $\mathcal{P/T}$ net is sequential if it does not offer any concurrent behavior. Hence, interleaving bisimulation equivalence is undecidable even for the subclass of sequential finite $\mathcal{P/T}$ nets. Esparza observed in [10] that all the non-interleaving bisimulation-based equivalences (in the spectrum ranging from interleaving bisimilarity to fully-concurrent bisimilarity [5]) collapse to interleaving bisimilarity over sequential PT nets. Hence, the proof in [23] applies to all these non-interleaving bisimulation equivalences as well.
\[\forall G_1 \text{ such that } m_1(G_1)m'_1, \exists G_2 \text{ such that } m_2(G_2)m'_2 \text{ with } l(G_1) = l(G_2) \text{ and } (m'_1, m'_2) \in R.\]

\[\forall G_2 \text{ such that } m_2(G_2)m'_2, \exists G_1 \text{ such that } m_1(G_1)m'_1 \text{ with } l(G_1) = l(G_2) \text{ and } (m'_1, m'_2) \in R.\]

Two markings \(m_1\) and \(m_2\) are step bisimilar (or step bisimulation equivalent), denoted by \(m_1 \sim_s m_2\), if there exists a step bisimulation \(R\) such that \((m_1, m_2) \in R\).

Of course, \(\sim_s\) is finer than \(\sim_i\); moreover, also step bisimilarity is undecidable for P/T nets having at least two unbounded places [10].

2.3 Causality-based Semantics

We outline some definitions, adapted from the literature (cf., e.g., [15, 4, 31, 14, 19]).

**Definition 7. (Acyclic net)** A P/T net \(N = (S, A, T, m_0)\) is acyclic if its flow relation \(F\) is acyclic (i.e., \(\not\exists x\) such that \(xF+x\), where \(F^+\) is the transitive closure of \(F\)).

The causal semantics of a marked P/T net is defined by a class of particular acyclic safe nets, where places are not branched (hence they represent a single run) and all arcs have weight 1. This kind of net is called causal net. We use the name \(C\) (possibly indexed) to denote a causal net, the set \(B\) to denote its places (called conditions), the set \(E\) to denote its transitions (called events), and \(L\) to denote its labels.

**Definition 8. (Causal net)** A causal net is a finite marked net \(C(m_0) = (B, L, E, m_0)\) satisfying the following conditions:

1. \(C\) is acyclic;
2. \(\forall b \in B \ [b]^* \leq 1 \land [b]^* \leq 1\) (i.e., the places are not branched);
3. \(\forall b \in B \ m_0(b) = \begin{cases} 1 & \text{if } [b]^* = \emptyset \\ 0 & \text{otherwise} \end{cases}\);
4. \(\forall e \in E \ [e]^*(b) \leq 1 \land [e]^*(b) \leq 1\) for all \(b \in B\) (i.e., all the arcs have weight 1).

We denote by \(\text{Min}(C)\) the set \(m_0\), and by \(\text{Max}(C)\) the set \(\{b \in B \mid [b]^* = \emptyset\}\).

Note that any reachable marking of a causal net is a set, i.e., this net is safe; in fact, the initial marking is a set and, assuming by induction that a reachable marking \(m\) is a set and enables \(e\), i.e., \(m[e]m'\), then also \(m' = (m \circ e)m \oplus e^*\) is a set, as the net is acyclic and because of the condition on the shape of the post-set of \(e\) (weights can only be 1).

As the initial marking of a causal net is fixed by its shape (according to item 3 of Definition 5), in the following, in order to make the notation lighter, we often omit the indication of the initial marking, so that the causal net \(C(m_0)\) is denoted by \(C\).

**Definition 9. (Moves of a causal net)** Given two causal nets \(C = (B, L, E, m_0)\) and \(C' = (B', L', E', m_0)\), we say that \(C\) moves in one step to \(C'\) through \(e\), denoted by \(C[e]C'\), if \(e \subseteq \text{Max}(C)\), \(E' = E \cup \{e\}\) and \(B' = B \cup e^*\).

**Definition 10. (Folding and Process)** A folding from a causal net \(C = (B, L, E, m_0)\) into a net system \(N(m_0) = (S, A, T, m_0)\) is a function \(\rho: B \cup E \rightarrow S \cup T\), which is type-preserving, i.e., such that \(\rho(B) \subseteq S\) and \(\rho(E) \subseteq T\), satisfying the following:

- \(L = A\) and \(l(e) = l(\rho(e))\) for all \(e \in E\);
- \(\rho(m_0) = m_0\), i.e., \(m_0(s) = [\rho^{-1}(s) \cap m_0]\);
- \(\forall e \in E \cdot \rho(e^*) = \rho(e)^*\), i.e., \(\rho(e^*)(s) = [\rho^{-1}(s) \cap e^*]\) for all \(s \in S\).

A pair \((C, \rho)\), where \(C\) is a causal net and \(\rho\) a folding from \(C\) to a net system \(N(m_0)\), is a process of \(N(m_0)\).

**Definition 11. (Moves of a process)** Let \(N(m_0) = (S, A, T, m_0)\) be a net system and let \((C_1, \rho_1)\), for \(i = 1, 2\), be two processes of \(N(m_0)\). We say that \((C_1, \rho_1)\) moves in one step to \((C_2, \rho_2)\) through \(e\), denoted by \((C_1, \rho_1) \rightarrow (C_2, \rho_2)\), if \(C_1(e)C_2\) and \(\rho_1 \subseteq \rho_2\). If \(\pi_1 = (C_1, \rho_1)\) and \(\pi_2 = (C_2, \rho_2)\), we denote the move as \(\pi_1 \rightarrow \pi_2\).

**Definition 12. (Causal-net bisimulation)** Let \(N = (S, A, T)\) be a finite P/T net. A causal-net bisimulation is a relation \(R\), composed of triples of the form \((\pi_1, g, \pi_2)\), where, for \(i = 1, 2\), \((C_i, \rho_i)\) are causal nets, with \(\pi_1 = (C_1, \rho_1)\), \(\pi_2 = (C_2, \rho_2)\), and \(g = \rho_2 \circ \rho_1\) is a function such that \(g^*(e) = [\rho_1^{-1}(e) \cap g^*]\) for all \(e \in E\).
Proposition 2. to state that way to define that two markings and in several different ways, depending on the chosen order of

Definition 15. that marking is related to itself, while the rule, assuming by induction

Example 1. Consider which is not an equivalence relation. Suppose we want to check whether because the residual does not belong to R. However, if we permute the second marking to s3 ⊕ s4, then we succeed because the required pairs (s1, s3) and (s2, s4) are both in R.

3 Place Bisimilarity

We now present the place bisimulation idea, introduced in [2] as an improvement of strong simulation, a behavioral relation proposed by Olderog in [31] on safe nets which fails to induce an equivalence relation. Our definition is formulated in a slightly different way: actually, it is a slight refinement of the original one which ensures that matched computations generate the same causal net. First, an auxiliary definition.

3.1 Additive Closure and Its Properties

Definition 15. (Additive closure) Given a PT net \( N = (S, A, T) \) and a place relation \( R \subseteq S \times S \), we define a marking relation \( R^\oplus \subseteq \mathcal{M}(S) \times \mathcal{M}(S) \), called the additive closure of \( R \), as the least relation induced by the following axiom and rule.

\[
(\theta, \theta) \in R^\oplus \\
(s_1, s_2) \in R \implies (m_1, m_2) \in R^\oplus \\
(\theta, \theta) \in R \implies (s_1 \oplus s_2, s_2 \oplus s_2) \in R^\oplus
\]

Note that, by definition, two markings are related by \( R^\oplus \) only if they have the same size; in fact, the axiom states that the empty marking is related to itself, while the rule, assuming by induction that \( m_1 \) and \( m_2 \) have the same size, ensures that \( s_1 \oplus m_1 \) and \( s_2 \oplus m_2 \) have the same size.

Proposition 1. For each relation \( R \subseteq S \times S \), if \( (m_1, m_2) \in R^\oplus \), then \( |m_1| = |m_2| \).

Note also that the membership \((m_1, m_2) \in R^\oplus\) may be proved in several different ways, depending on the chosen order of the elements of the two markings and on the definition of \( R \). For instance, if \( R = \{ (s_1, s_1), (s_1, s_2), (s_2, s_2), (s_2, s_3) \} \), then \( (s_1 \oplus s_2, s_2 \oplus s_2) \in R^\oplus \) can be proved by means of the pairs \((s_1, s_3)\) and \((s_2, s_4)\), as well as by means of \((s_1, s_4)\) and \((s_2, s_3)\). An alternative way to define that two markings \( m_1 \) and \( m_2 \) are related by \( R^\oplus \) is to state that \( m_1 \) can be represented as \( s_1 \oplus s_2 \oplus \ldots \oplus s_k \) and \( m_2 \) can be represented as \( s'_1 \oplus s'_2 \oplus \ldots \oplus s'_k \) and \( (s_i, s'_i) \in R \) for \( i = 1, \ldots, k \).

Proposition 2. 17 For each place relation \( R \subseteq S \times S \), the following hold:

1) If \( R \) is an equivalence relation, then \( R^\oplus \) is an equivalence relation.
2) If \( R_1 \subseteq R_2 \), then \( R_1 \subseteq R_2^\oplus \), i.e., the additive closure is monotone.
3) If \((m_1, m_2) \in R^\oplus \) and \((m'_1, m'_2) \in R^\oplus \), then \((m_1 \oplus m'_1, m_2 \oplus m'_2) \in R^\oplus \), i.e., the additive closure is additive.

4) If \( R \) is an equivalence relation, \((m_1 \oplus m'_1, m_2 \oplus m'_2) \in R^\oplus \) and \((m_1, m_2) \in R^\oplus \), then \((m'_1, m'_2) \in R^\oplus \), i.e., the additive closure of an equivalence place relation is subtractive. □

When \( R \) is an equivalence relation, it is rather easy to check whether two markings are related by \( R^\oplus \). An algorithm, described in [17], establishes whether an \( R \)-preserving bijection exists between the two markings \( m_1 \) and \( m_2 \) of equal size \( k \) in \( O(k^2) \) time. Another algorithm, described in [18], checks whether \((m_1, m_2) \in R^\oplus \) in \( O(n) \) time, where \( n \) is the size of \( S \). However, these performant algorithms heavily rely on the fact that \( R \) is an equivalence relation, hence also subtractive (case 4 of Proposition 2). If \( R \) is not an equivalence relation, which is typical for place bisimulations, the naive algorithm for checking whether \((m_1, m_2) \in R^\oplus \) would simply consider \( m_1 \) represented as \( s_1 \oplus s_2 \oplus \ldots \oplus s_k \) and then would scan all the possible permutations of \( m_2 \), each represented as \( s'_1 \oplus s'_2 \oplus \ldots \oplus s'_k \), to check that \((s_i, s'_i) \in R \) for \( i = 1, \ldots, k \). Of course, this naive algorithm has worst-case complexity \( O(k!) \).

Example 1. Consider \( R = \{ (s_1, s_3), (s_1, s_4), (s_2, s_4) \} \), which is not an equivalence relation. Suppose we want to check whether because each of the \( s_2, s_3 \) does not belong to \( R \). However, if we permute the second marking to \( s_3 \oplus s_4 \), then we succeed because the required pairs \((s_1, s_3)\) and \((s_2, s_4)\) are both in \( R \).

Nonetheless, the problem of checking if \((m_1, m_2) \in R^\oplus \) has polynomial time complexity because it can be considered an instance of the problem of finding a perfect matching in a bipartite graph, where the nodes are the tokens in the two markings and the edges are defined by the relation \( R \). In fact, the definition of the bipartite graph takes \( O(k^2) \) time (where \( k = |m_1| = |m_2| \)) and, then, the Hopcroft-Karp-Karzanov algorithm [22, 25] for computing the maximum matching has worst-case time complexity \( O(h^2 \sqrt{k}) \), where \( h \) is the number of the edges in the bipartite graph (\( h \leq k^2 \)) and to check whether the maximum matching is perfect can be done simply by checking that the size of the matching equals the number of nodes in each partition, i.e., \( k \). Hence, in evaluating the complexity of the algorithm in Section 5, we assume that the complexity of checking whether \((m_1, m_2) \in R^\oplus \) is \( O(k^2 \sqrt{k}) \).

A related problem is that of computing, given a marking \( m_1 \) of size \( k \), the set of all the markings \( m_2 \) such that \((m_1, m_2) \in R^\oplus \). This problem can be solved with a worst-case time complexity of \( O(n^k) \) because each of the \( k \) tokens in \( m_1 \) can be related via \( R \) to \( n \) places at most.

Now we list some useful, and less obvious, properties of additively closed place relations (proof in [17]).

Proposition 3. For each place relations \( R, R_1, R_2 \subseteq S \times S \), the following hold:

1) If \( \emptyset^\oplus = \{ (\theta, \theta) \} \), i.e., the additive closure of the empty place relation yields a singleton marking relation, relating the empty marking to itself.
2) \((\mathcal{J}_S)^\oplus = \mathcal{J}_S \), i.e., the additive closure of the identity relation on places \( \mathcal{J}_S = \{ (s, s) \mid s \in S \} \) yields the identity relation on markings \( \mathcal{J}_M = \{ (m, m) \mid m \in \mathcal{M}(S) \} \).
3) \((R^\oplus)^{-1} = (R^{-1})^\oplus \), i.e., the inverse of an additively closed relation \( R \) equals the additive closure of its inverse \( R^{-1} \).
4) \((R_1 \circ R_2)^\oplus = (R_1^\oplus) \circ (R_2^\oplus) \), i.e., the additive closure of the composition of two place relations equals the compositions of their additive closures. □
3.2 Place Bisimulation and its Properties

We are now ready to introduce place bisimulation, which is a non-interleaving behavioral relation defined over the net places.

**Definition 16. (Place Bisimulation)** Let \( N = (S, A, T) \) be a P/T net. A place bisimulation is a relation \( R \subseteq S \times S \) such that if \((m_1, m_2) \in R^0\) then

- \( \forall t_1 \text{ such that } m_1 \models t_1 \cdot m_1', \exists t_2 \text{ such that } m_2 \models t_2 \cdot m_2' \) with \( (t_1', t_2') \in R^0 \), \( l(t_1) = l(t_2) \), \( (t_1', t_2') \in R^0 \) and, moreover, \((m_1 \oplus t_1, m_2 \oplus t_2) \in R^0 \); and symmetrically,

- \( \forall t_2 \text{ such that } m_2 \models t_2 \cdot m_2', \exists t_1 \text{ such that } m_1 \models t_1 \cdot m_1' \) with \( (t_1', t_2') \in R^0 \), \( l(t_1) = l(t_2) \), \( (t_1', t_2') \in R^0 \) and, moreover, \((m_1 \ominus t_1, m_2 \ominus t_2) \in R^0 \).

Two markings \( m_1 \) and \( m_2 \) are place bisimilar, denoted by \( m_1 \sim_P m_2 \), if there exists a place bisimulation \( R \) such that \((m_1, m_2) \in R^0\). \( \square \)

Note that, from \((m_1 \ominus t_1, m_2 \ominus t_2) \in R^0 \) and \((t_1', t_2') \in R^0 \), we can derive \((m_1', m_2') \in R^0 \) by additivity of \( R^0 \) (cf. Proposition 2). Actually, the original definition of place bisimulation in \( \square \) requires the condition \((m_1', m_2') \in R^0 \) instead of the stronger condition \((m_1 \ominus t_1, m_2 \ominus t_2) \in R^0 \). We will see in Section 5 that the original definition may not fully respect causality.

Note that a place relation \( R \subseteq S \times S \) is a place bisimulation if for all \((m_1, m_2) \in R^0\) the two place bisimulation conditions above hold. So, it seems that infinitely many verifications are necessary to establish whether \( R \) is a place bisimulation. In Section 5 we prove that, actually, only finitely many verifications are necessary.

In order to prove that \( \sim_P \) is an equivalence relation, we now list some useful properties of place bisimulation relations.

**Proposition 4.** For each P/T net \( N = (S, A, T) \), the following hold:

1. The identity relation \( \mathcal{S}_S = \{(s, s) \mid s \in S\} \) is a place bisimulation;
2. The inverse relation \( R^{-1} = \{(s', s) \mid (s, s') \in R\} \) of a place bisimulation \( R \) is a place bisimulation;
3. The relational composition \( R_1 \circ R_2 = \{(s, s') \mid \exists s'' \text{ such that } (s, s'') \in R_1 \wedge (s'', s') \in R_2\} \) of two place bisimulations \( R_1 \) and \( R_2 \) is a place bisimulation.

**Proof:** The proof is almost standard, due to Proposition 3. (1) \( \mathcal{S}_S \) is a place bisimulation as for each \((m, m) \in \mathcal{S}_S\), whatever transition \( t \) the left (or right) marking \( m \) performs a transition (say, \( m[t]m' \)), the right (or left) instance of \( m \) in the pair does exactly the same transition \( m[t]m' \) and, of course, \((t_1, t_1) \in \mathcal{S}_S\), \((t_1', t_1') \in \mathcal{S}_S\), \( l(t) = l(t) \), \((t_1', t_1') \in \mathcal{S}_S\), by Proposition 2, as required by the place bisimulation definition.

(2) Suppose \((m_2, m_1) \in R^{-1}\) and \(m_2[t_2]m_2'\) by Proposition 3 (1). \((m_2, m_1) \in R^{-1}\) and so \((m_1, m_2) \in R^0\). Since \( R \) is a place bisimulation, the second item of the place bisimulation game ensures that there exist \( t_1 \) and \( m_1' \) such that \( m_1 \models t_1 \cdot m_1' \) with \((t_1', t_2') \in R^0\), \( l(t_1) = l(t_1) \), \((t_1', t_2') \in R^0\) and \((m_2 \ominus t_2, m_1 \ominus t_1) \in \mathcal{S}_S\), as required by the place bisimulation definition.

(3) Suppose \((m, m') \in \mathcal{S}_A \) and \(m(t) \models m_1.\) By Proposition 3 (4), we have that \((m, m') \in R^0 \) and \((m(t), m(t')) \in \mathcal{S}_S\), as required by the place bisimulation definition.\( \square \)

Fig. 2. Two fully-concurrent bisimilar markings, which are not place bisimilar

**Proposition 5.** For each P/T net \( N = (S, A, T) \), relation \( \sim_P \subseteq \mathcal{M}(S) \times \mathcal{M}(S) \) is an equivalence relation.

**Proof:** As the identity relation \( \mathcal{S}_S \) is a place bisimulation by Proposition 1, we have that \( \mathcal{S}_S \subseteq \sim_P \), and so \( \sim_P \) is reflexive. Symmetry derives from the following argument. For any \((m, m') \in \sim_P \), there exists a place bisimulation \( R \) such that \((m, m') \in R^0\); by Proposition 2, relation \( R^{-1} \) is a place bisimulation, and so \((m', m) \in \sim_P \). By Proposition 3 (3), \( R \circ R_1 \) is a place bisimulation such that \((m, m') \in \sim_P \). Hence, \((m', m) \in \sim_P \). Transitivity also holds for \( \sim_P \). Let \((m, m') \in \sim_P \) and \((m', m'') \in \sim_P \); hence, there exist two place bisimulations \( R_1 \) and \( R_2 \) such that \((m', m'') \in R_1^0 \) and \((m', m'') \in R_2^0 \). By Proposition 3 (4), \((R_1 \circ R_2)^0 \) is a place bisimulation such that \((m, m'') \in \sim_P \). Hence, \((m', m'') \in \sim_P \). \( \square \)

**Proposition 6. (Place bisimilarity is finer than interleaving bisimilarity)**

Given a P/T net \( N = (S, A, T) \) and two markings \( m_1, m_2 \), if \( m_1 \sim_P m_2 \), then \( m_1 \sim_{int} m_2 \).

**Proof:** If \( m_1 \sim_P m_2 \), then there exists a place bisimulation \( R \) such that \((m_1, m_2) \in R^0\). Note that if \( R \) is a place bisimulation, then \( R^0 \) is an interleaving bisimulation, and so \( m_1 \sim_{int} m_2 \). \( \square \)

The implication above is strict, i.e., it is possible to find a P/T net and two markings that are interleaving bisimilar but not place bisimilar. For instance, in the CCS terminology, the marking for \( a. b. 0 + b. a. 0 \) and that for \( a. 0 \mid b. 0 \) (see, e.g., [16]). It is also possible to show that place bisimilarity implies step bisimilarity [30] (cf. the subsequent Example 11 and Theorem 5). As a matter of fact, place bisimilarity is a truly concurrent behavioral equivalence, which is slightly finer than causal-net bisimilarity [19] (or, equivalently, structure preserving bisimilarity [14]), in turn slightly finer than fully-concurrent bisimilarity 8.

The following examples illustrate these relationships.

**Example 2.** Consider the net in Figure 2. Note that it is not possible to build a place bisimulation relating \( s_1 \) and \( s_3 \).
because the post-sets of the $a$-labeled transitions from $s_1$ and $s_3$
(i.e., $2\cdot s_2$ and $s_4$, respectively) have different size. Of
course, the two markings $s_1$ and $s_3$ are not causal-net bisimilar,
as they generate different causal nets. However, $s_1$ and $s_3$ are
fully-concurrent bisimilar [5], because both can perform the
same partial order of events (i.e., $b$ caused by $a$).

**Example 3.** A more intriguing example showing the
difference between place bisimilarity and causal-net bisimilarity
is about the net in Figure 3. Of course, $s_1$ and $s_5$ are causal-net bisimi-
lar, because both generate the same causal nets. However, it is
not possible to build a place bisimulation relating $s_1$ and $s_5$
because this place relation would require the pair $(s_2, s_6)$, but
$s_2$ and $s_6$ are not place bisimilar; in fact, $2\cdot s_2$ is stuck, while
$2\cdot s_6$ can perform $b$. □

By Definition [16] place bisimilarity $\sim_p$ can be defined as follows:
$\sim_p = \bigcup \{ R^p \mid R$ is a place bisimulation $\}$. By
monotonicity of the additive closure (Proposition 2(2)), if $R_1 \subseteq
R_2$, then $R_1^p \subseteq R_2^p$. Hence, we can restrict our attention to
maximal place bisimulations only:
$\sim_p = \bigcup \{ R^p \mid R$ is a maximal place bisimulation $\}$.
However, it is not true that
$\sim_p = \bigcup \{ R \mid R$ is a maximal place bisimulation $\}^p$
because the union of place bisimulations may not be a place
bisimilation (as already observed in [2]), so that its definition is
not coinductive. We illustrate this fact by means of the following
tiny example.

**Example 4.** Consider the simple P/T net in Figure 4 with $S =
\{s_1, s_2, s_3\}$. It is rather easy to realize that there are only two
maximal place bisimulations, namely:
\[
R_1 = \mathcal{F}_S \setminus \{ (s_1, s_1), (s_2, s_2), (s_3, s_3) \}\]
and
\[
R_2 = (R_1 \setminus \mathcal{F}_{\{s_1, s_2\}}) \cup \{ (s_1, s_2), (s_2, s_1) \} =
\{ (s_1, s_2), (s_2, s_1), (s_3, s_3) \},
\]
only one of which is an equivalence relation. However, note
that their union $R = R_1 \cup R_2$ is not a place bisimulation. In
fact, on the one hand $(s_1 \oplus s_1, s_1 \oplus s_2) \in R_1^p$, but, on the other
hand, these two markings do not satisfy the place bisimulation
game, because $s_1 \oplus s_1$ is stuck, while $s_1 \oplus s_2$ can fire the
$a$-labeled transition, reaching $s_3$.

Since $R_1$ and $R_2$ are the two maximal place bisimulations, then
we can prove that $m \sim_p m$ for each marking $m \in \mathcal{M}(S)$ because
$(m, m) \in R_1^p$, as well as that, e.g., $2\cdot s_1 \oplus s_2 \sim_p s_1 \oplus 2\cdot s_2$ as
$2\cdot s_1 \oplus s_2, s_1 \oplus 2\cdot s_2 \in R_2^p$.

Note that the equivalence relation $\sim_{p_6}$ characterized in [3] is
$R_1^p$, which is an equivalence relation indeed, because $R_1$ is
an equivalence relation and, by Proposition 2(1), also $R_1^p$ is
an equivalence relation. Instead $\sim_p = R_1^p \cup R_2^p$, so that these
two equivalences are different. Note that $\sim_p$ is an equivalence
relation, indeed, as it is reflexive ($R_1 = (R_1^p)^p = R_1^p \subseteq \sim_p$),
symmetric (each maximal place bisimulation is symmetric, the
additive closure of a symmetric place relation is symmetric and,
finally, the union of symmetric relations is symmetric) and transitive
(maximal place relations are closed by relational composition; in fact, $R_1 \circ R_1 = R_1$, $R_1 \circ R_2 = R_2 \circ R_1 = R_2$ and
$R_2 \circ R_2 = R_1$). □

**Example 5.** Consider the net in Figure 5 where $S = \{s_1, s_2,
s_3, s_4, s_5, s_6, s_7, s_8\}$. It is not too difficult to realize that the six
maximal place bisimulations are the following:
\[
R_1 = \mathcal{F}_S \cup \{ (s_4, s_8), (s_8, s_4) \},
\]
which is an equivalence relation,\n\[
R_2 = (R_1 \setminus \mathcal{F}_{\{s_2, s_3\}}) \cup \{ (s_2, s_3), (s_3, s_2) \},
\]
\[
R_3 = (R_1 \setminus \mathcal{F}_{\{s_4, s_7\}}) \cup \{ (s_6, s_7), (s_7, s_6) \},
\]
\[
R_4 = (R_1 \setminus \mathcal{F}_{\{s_2, s_3, s_5, s_6\}}) \cup
\cup \{ (s_2, s_3), (s_3, s_2), (s_5, s_6), (s_6, s_5) \},
\]
\[
R_5 = (R_1 \setminus \mathcal{F}_{\{s_2, s_3, s_5, s_6, s_7\}}) \cup
\cup \{ (s_2, s_3), (s_3, s_2), (s_5, s_6), (s_6, s_5) \},
\]
\[
R_6 = (R_1 \setminus \mathcal{F}_{\{s_2, s_3, s_5, s_6, s_7\}}) \cup
\cup \{ (s_2, s_3), (s_3, s_2), (s_5, s_6), (s_6, s_5) \}.
\]
The equivalence relation $\sim_{p_{60}}$ characterized in [3] is $R_1^p$, while
$\sim_p = R_1^p \cup R_2^p \cup R_3^p \cup R_4^p \cup R_5^p \cup R_6^p$. □

**Example 6.** As a tiny case study, let us consider the two
unbounded producer-consumer systems in Figure 6 and 7 where
the former can be considered the specification and the latter its
implementation. Note that if a token is present in the producer
place $P$ (or $P_1$), then the transition labeled by $prod$ can be performed at will, with the effect that the number of tokens accumulated into place $P'$ (or $P_1'$) can grow unboundedly; hence, the reachable markings from $P \oplus C$ (or $P_1 \oplus C_1$) are infinitely many, so that the state space of these two systems is infinite. In order to prove that $P \oplus C \sim_P P_1 \oplus C_1$, we can try to build a place bisimulation $R$ which must contain at least the pairs $(P,P_1),(C,C_1)$; then, in order to match the $prod$-labeled transitions, we see that also the pairs $(P',P_1'),(P'',P_1'')$ are needed, and then, in order to match the $\tau$-labeled transitions, also the pair $(C',C_1')$ must be considered. The resulting relation is $R = \{(P,P_1),(P',P_1'),(P'',P_1''),(C,C_1),(C',C_1')\}$, which is a place bisimulation, indeed (formally provable as explained in the subsequent Lemma 8), justifying that $P \oplus C \sim_P P_1 \oplus C_1$. From $R$ we can also derive that, e.g., $P \oplus 2 \cdot P' \oplus C'$ is place bisimilar to $P_1 \oplus P_1' \oplus P_1'' \oplus C_1'$.

Example 7. As a further example, consider the nets in Figure 8 that model a simple system with two types of sequential processes: those that can perform $b$ and, in doing so, generate two instances of the same process type (i.e., $s_1, s_2, s_3, s_4, s_5, s_6, s_7, s_8$); and those that can perform $a$ and, by doing so, become a process of the first type (i.e., $s_1, s_2, s_3, s_4, s_5, s_6, s_7, s_8$). It is easy to see that $R = \{(s_1,s_8),(s_2,s_8),(s_3,s_8),(s_4,s_8),(s_5,s_9),(s_6,s_9),(s_7,s_9)\}$ is a place bisimulation. Therefore, e.g., $s_1 \oplus 2 \cdot s_3 \oplus s_4 \oplus s_7$ is place bisimilar to $3 \cdot s_8 \oplus 2 \cdot s_9$.

4 Place Bisimilarity Implies Causal-net Bisimilarity

Now we want to prove that our definition of place bisimulation does respect the intended causal semantics of Petri nets, by proving that place bisimilarity $\sim_P$ implies causal-net bisimilarity $\sim_{cn}$. The reverse implication does not hold, as illustrated in Example 3.

Theorem 1. For each P/T net $N = (S,A,T)$, if $m_1 \sim_P m_2$ then $m_1 \sim_{cn} m_2$.

Proof: If $m_1 \sim_P m_2$, then there exists a place bisimulation $R_1$ such that $(m_1,m_2) \in R_1$. Let us consider

$$R_2 \triangleq \{(p_1,C,p_2)|(C,p_1) \text{ is a process of } N(m_1) \text{ and } (C,p_2) \text{ is a process of } N(m_2) \text{ and } \forall b \in \text{Max}(C) \quad (p_1(b),b,p_2(b)) \in R_1\}.$$

We want to prove that $R_2$ is a causal-net bisimulation. First of all, consider a triple of the form $(p_1^0,C^0,p_2^0)$, where $C^0$ is the causal net without events and $p_1^0,p_2^0$ are such that $p_1^i(Min(C^0)) = p_2^i(\text{Max}(C^0)) = p_1^i(b)$ for $i = 1,2$, and $(p_1^0(b),b,p_2^0(b)) \in R_1$ for all $b \in B^0$. Then $(p_1^0,C^0,p_2^0)$ must belong to $R_2$, because $(C^0,p_1^0)$ is a process of $N(m_1)$, for $i = 1,2$ and, by hypothesis, $(m_1,m_2) \in R_1$. Hence, if $R_2$ is a causal-net bisimulation, then the triple $(p_1^0,C^0,p_2^0) \in R_2$ ensures that $m_1 \sim_{cn} m_2$.

Now, assume $(p_1,C,p_2) \in R_2$. In order for $R_2$ to be a cn-bisimulation, we must prove that

1) $\forall t_1,C',p_1' \text{ such that } (C,p_1) \xrightarrow{t_1} (C',p_1')$, where $p_1'(e) = t_1$, $\exists t_2,p_2' \text{ such that } (C,p_2) \xrightarrow{t_2} (C',p_2')$, where $p_2'(e) = t_2$, and $(p_1',C',p_2') \in R_2$.

2) symmetrical, if $(C,p_2)$ moves first.

Assume $(C,p_1) \xrightarrow{e} (C',p_1')$ with $p_1'(e) = t_1$. Recall that if $(p_1,C,p_2) \in R_2$ then $\forall b \in \text{Max}(C)$ we have $(p_1(b),b,p_2(b)) \in R_1$. This means that $(p_1(e)[t_1],t_1) \in R_1$. As $R_1$ is a place bisimulation, to the move $p_1(e)[t_1]$, marking $p_2(e)$ can respond with $p_2(e)[t_2]$ such that $p_1[e,t_2] \in R_1$, $l(t_1) = l(t_2)$ and $(p_1[e,t_2],t_2) \in R_1$. Therefore, it is possible to derive $(C,p_2) \xrightarrow{e} (C',p_2')$, where $p_2'$ is such that $p_2'(e) = t_2$ and $(p_1'[e],p_2'[e]) \in R_1$ for each $b \in e^*$ (which is really possible because $[t_1,t_2] \in R_1$). Since for all $b \in \text{Max}(C) \otimes e$ we already know that $(p_1(b),p_2(b)) \in R_1$, it follows that for all $b' \in \text{Max}(C)$ it holds that $(p_1'[b'],p_2'[b']) \in R_1$. As a consequence $(p_1',C',p_2') \in R_2$. 

Fig. 6. An unbounded producer-consumer system

Fig. 7. Another unbounded producer-consumer system

Fig. 8. Two place bisimilar nets
The case when \((C, p_2)\) moves first is symmetrical and therefore omitted. Thus, \(R_2\) is a causal-net bisimulation and, since \((p_1, C, p_0) \in R_2\), we have \(m_1 \sim_{cn} m_2\).

Note that this proof is correct also if we use the original definition of place bisimulation in \([2]\). As a matter of fact, we will argue in the next section that the original definition and our own are different formulations of the same concept: a relation \(R\) is a place bisimulation for the original definition if and only if \(R\) is a place bisimulation according to our more restrictive definition, so that they define the same equivalence relation. However, there is a subtle difference between the two variants: the following example shows that, according to the original definition of place bisimulation, matched computations in the place bisimulation game may generate different causal nets.

**Example 8.** Consider the net in Figure 9, where we call by \(t_i\) the transition \((s_i, a, s_i)\) for \(i = 1, \ldots, 4\). Consider also the relation \(R = \{(s_1, s_3), (s_1, s_4), (s_2, s_4)\}\) we have discussed in Example 1. It is an easy task to check that \(R\) is a place bisimulation for both the original definition in [2] and our Definition 1. However, it may happen that matched computations w.r.t. the original place bisimulation definition do originate different causal nets. Consider the markings \(s_1 \oplus s_2\) and \(s_3 \oplus s_4\). Of course, \((s_1 \oplus s_2, s_3 \oplus s_4) \in R^\oplus\) because \((s_1, s_3) \in R\) and \((s_2, s_4) \in R\). However, if \(s_1 \oplus s_2, s_1 \oplus s_4, s_3 \oplus s_4\) can reply also with \(s_3 \oplus s_4, s_3 \oplus s_4\) according to the original definition (but not according to ours, because \((s_2, s_4) \notin R\)). Now, if \(s_1 \oplus s_2, s_1 \oplus s_2, s_1 \oplus s_4\) can reply with \(s_3 \oplus s_4\) according to both definitions. Hence, by condition 1, there exists a transition \(t_2\) such that \(t_2 \in \pi_1 \oplus \pi_2 \oplus \pi_3\), \(t_1 = l(t_1) = l(t_2)\), and \((t_1^*, t_2^*) \in R^\oplus\). The implication from left to right is obvious: if \(R\) is a place bisimulation, then for sure conditions 1 and 2 are satisfied. For the converse implication, assume that conditions 1 and 2 are satisfied; then we have to prove that the place bisimulation game for \(R\) holds for all pairs \((m_1, m_2)\) in \(R^\oplus\). Let \(q = \{(s_1, s_1'), (s_2, s_2'), \ldots, (s_k, s_k')\}\) be any multiset of associations that can be used to prove that \((m_1, m_2) \in R^\oplus\). So this means that \(m_1 = s_1' \oplus s_2' \oplus \ldots \oplus s_k'\) and that \((s_i, s_i') \in R\) for \(i = 1, \ldots, k\).

Of course, \((s_1, s_1') \in R\) and \((s_2, s_2') \in R\), hence the worst-case. \(\Box\)

Fig. 9. A simple net with replicas

---

**Lemma 1.** Given a P/T net \(N = (S, A, T)\) and a place relation \(R \subseteq S \times S\), it is decidable if \(R\) is a place bisimulation.

**Proof:** We want to prove that \(R\) is a place bisimulation if and only if the following two conditions are satisfied:

1) \(\forall t_1 \in T, \forall m \text{ such that } (t_1, m) \in R^\oplus,\)

   \[(a) \exists t_2 \text{ such that } m = t_2, \text{ with } l(t_1) = l(t_2) \text{ and } (t_1^*, t_2^*) \in R^\oplus.\]

2) \(\forall t_2 \in T, \forall m \text{ such that } (m, t_2) \in R^\oplus,\)

   \[(b) \exists t_1 \text{ such that } m = t_1, \text{ with } l(t_1) = l(t_2) \text{ and } (t_1^*, t_2^*) \in R^\oplus.\]

The implication from left to right is obvious: if \(R\) is a place bisimulation, then for sure conditions 1 and 2 are satisfied. For the converse implication, assume that conditions 1 and 2 are satisfied; then we have to prove that the place bisimulation game for \(R\) holds for all pairs \((m_1, m_2)\) in \(R^\oplus\). Let \(q = \{(s_1, s_1'), (s_2, s_2'), \ldots, (s_k, s_k')\}\) be any multiset of associations that can be used to prove that \((m_1, m_2) \in R^\oplus\). So this means that \(m_1 = s_1' \oplus s_2' \oplus \ldots \oplus s_k'\) and that \((s_i, s_i') \in R\) for \(i = 1, \ldots, k\).

If \(m_1(t_1)m_1'\), then \(m_1' = m_1 \oplus t_1 \oplus t_1^*\). Consider any multiset of associations \(p = \{(S_1, S_1'), \ldots, (S_3, S_3')\} \subseteq q\). Since \(S_1' \oplus S_2' \oplus S_3' \in R^\oplus\), therefore, by condition 1, there exists a transition \(t_2\) such that \(t_2 = S_1' \oplus S_2' \oplus S_3'\), \(l(t_1) = l(t_2)\), and \((t_1^*, t_2^*) \in R^\oplus\. Hence, since \(t_2 \subseteq m_2\), also \(m_2(t_2)m_2'\) is firable, where \(m_2' = m_2 \oplus t_2 \oplus t_2^*\), so that \((t_1^*, t_2^*) \in R^\oplus\. And the same for condition 2. Hence, this procedure has worst-case time complexity \(O(q \cdot n^{p_1} \cdot p_2 \cdot \sqrt{p_2})\), where \(q = |T|, n = |S|\) and \(p_1, p_2\) are the least numbers such that \(|t_1| \leq p_1\) and \(|t_2| \leq p_2\) for all \(t \in T\), as the number of markings \(m\) related via \(R\) to \(t_1^*\) is \(n^{p_1}\) at most, and checking whether \((t_1^*, t_2^*) \in R^\oplus\) takes \(O(p_2 \cdot \sqrt{p_2})\) in the worst-case. \(\Box\)

It is not difficult to realize that the characterization of a place bisimulation described in the lemma above holds also for the original definition of place bisimulation in [2]. This means that if \(R\) is a place bisimulation according to the original definition, then the two conditions 1) and 2) in the proof of Lemma 1 are satisfied for \(R\); and, if these two conditions are satisfied for \(R\), then \(R\) is a place bisimulation according to our own, more demanding definition. Therefore, a relation \(R\) is a place bisimulation according to the original definition if and only if \(R\) is a place bisimulation according to our own variant definition. Hence, the two behavioral equivalences derived from these two slightly different definitions do coincide.

---

**5 Place Bisimilarity is Decidable**

Since the union of place bisimulations may be not a place bisimulation, its definition is not coinductive and, therefore, the well-known polynomial algorithms [24, 32] for computing the largest bisimulation on LTSs cannot be adapted to compute place bisimilarity.

In order to prove that \(\sim_{cn}\) is decidable, we first need a technical lemma which states that it is decidable to check whether a place relation \(R \subseteq S \times S\) is a place bisimulation.
Theorem 2. (Place bisimilarity is decidable) Given a P/T net \( N = (S, A, T) \), for each pair of markings \( m_1 \) and \( m_2 \), it is decidable whether \( m_1 \sim_p m_2 \).

Proof: If \( |m_1| \neq |m_2| \), then \( m_1 \sim_p m_2 \) by Proposition [1]. Otherwise, we can assume that \( |m_1| = k = |m_2| \). Since \( S \) is finite, the set of all the place relations over \( S \) is finite as well. Let us list all the place relations as follows: \( R_1, R_2, \ldots, R_q \). Therefore, for \( i = 1, \ldots, n \), by Lemma [2] we can decide whether the place relation \( R_i \) is a place bisimulation and, in such a case, we can check whether \( (m_1, m_2) \in R_i^\circ \) in \( O(k^2 \sqrt{k}) \) time. As soon as we have found a place bisimulation \( R_i \) such that \( (m_1, m_2) \in R_i^\circ \), we stop concluding that \( m_1 \sim_p m_2 \). If none of the \( R_i \) is a place bisimulation such that \( (m_1, m_2) \in R_i^\circ \), then we can conclude that \( m_1 \not\sim_p m_2 \).

About the complexity of this decision procedure, we note that if \( |S| = n \), then the set of all the place relations over \( S \) has cardinality \( 2^n \). Moreover, the procedure for checking whether a place relation \( R_i \) in this set is a place bisimulation has worst-case time complexity \( O(q \cdot n^m \cdot \sqrt{k} \cdot (2^2 \sqrt{k})) \). Finally, if \( R_i \) is a place bisimulation, the cost of checking whether \( (m_1, m_2) \in R_i^\circ \) is \( O(k^2 \sqrt{k}) \) if the two markings have size \( k \). Summing up, the procedure is exponential in the size of the net.

6 A COARSER VARIANT: D-PLACE BISIMILARITY

Now we want to define a slightly weaker variant of place bisimulation, we call \( d \)-place bisimulation, which may relate a place \( s \) also to the empty marking \( \emptyset \).

In order to provide the definition of \( d \)-place bisimulation, we need first to extend the domain of a place relation: the empty marking \( \emptyset \) is considered as an additional place, so that a place relation is defined not on \( S \), rather on \( S \cup \{ \emptyset \} \). Hence, the symbols \( r_1 \) and \( r_2 \) that occur in the following definitions, can only denote either the empty marking \( \emptyset \) or a single place \( s \). Now we extend the idea of additive closure to these more general place relations, yielding \( d \)-additive closure.

Definition 17. (D-additive closure) Given a P/T net \( N = (S, A, T) \) and a place relation \( R \subseteq (S \cup \{ \emptyset \}) \times (S \cup \{ \emptyset \}) \), we define a marking relation \( R^\circ \subseteq \mathcal{M}(S) \times \mathcal{M}(S) \), called the \( d \)-additive closure of \( R \), as the least relation induced by the following axiom and rule.

\[
\begin{align*}
(\emptyset, \emptyset) \in R^\circ \\
\forall (r_1, r_2) \in R, \quad (m_1, m_2) \in R^\circ \quad \Rightarrow \quad (r_1 \oplus m_1, r_2 \oplus m_2) \in R^\circ
\end{align*}
\]

Note that if two markings are related by \( R^\circ \), then they may have different size; in fact, even if the axiom relates the empty marking to itself (so two markings with the same size), as \( R \subseteq (S \cup \{ \emptyset \}) \times (S \cup \{ \emptyset \}) \), it may be the case that \( (\emptyset, s) \in R \), so that, assuming \((m_1, m_2) \in R^\circ \) with \( |m_1| = |m_2| \), we get that the pair \((m_1, m_2) \oplus (\emptyset, \emptyset) \) belongs to \( R^\circ \) as \( \emptyset \) is the identity for the operator of multisets union. Hence, Proposition [1] which is valid for place relations defined over \( S \), is not valid for place relations defined over \( S \cup \{ \emptyset \} \). However, the properties in Propositions [2] and [3] hold also for these more general place relations. Note that checking whether \((m_1, m_2) \in R^\circ \) has complexity \( O(k^2 \sqrt{k}) \), where \( k \) is the size of the largest marking.

Definition 18. (D-place bisimulation) Let \( N = (S, A, T) \) be a P/T net. A \( d \)-place bisimulation is a relation \( R \subseteq (S \cup \{ \emptyset \}) \times (S \cup \{ \emptyset \}) \) such that if \( (m_1, m_2) \in R^\circ \) then

- \( \forall r_1 \) such that \( m_1 \circ r_1 \), \( \exists r_2 \) such that \( m_2 \circ r_2 \), with \((r_1, r_2) \in R^\circ \), \( \|r_1\| = \|r_2\| \), \((r_1^*, r_2^*) \in R^\circ \) and \((m_1 \oplus \emptyset, m_2 \oplus \emptyset) \in R^\circ \).
- \( \forall r_2 \) such that \( m_2 \circ r_2 \), \( \exists r_1 \) such that \( m_1 \circ r_1 \), with \((r_1, r_2) \in R^\circ \), \( \|r_1\| = \|r_2\| \), \((r_1^*, r_2^*) \in R^\circ \) and \((m_1 \oplus \emptyset, m_2 \oplus \emptyset) \in R^\circ \).

Two markings \( m_1 \) and \( m_2 \) are \( d \)-place bisimilar, denoted by \( m_1 \sim_d \emptyset \), if there exists a \( d \)-place bisimulation \( R \) such that \((m_1, m_2) \in R^\circ \).

It is easy to see that, by additivity of \( R^\circ \), from \((m_1 \oplus r_1, m_2 \oplus r_2) \in R^\circ \) and \((r_1^*, r_2^*) \in R^\circ \) we derive \((m_1^*, m_2^*) \in R^\circ \).

Example 9. Consider the net in Figure 10. It is not difficult to realize that \( R = \{(s_1, s_1), (s_1, s_2), (s_2, s_2), (s_3, \emptyset)\} \) is a \( d \)-place bisimulation. Hence, this example shows that \( d \)-place bisimilarity is strictly coarser than place bisimilarity, and not finer than causal-net bisimilarity, because \( s_1 \) and \( s_3 \) generate different causal nets.

The places that are related to \( \emptyset \) (i.e., \( s_3 \) and \( s_5 \)) are deadlocks, i.e., they have empty post-set. However, it may happen that a \( d \)-place bisimulation can also relate a place with non-empty post-set to \( \emptyset \). In fact, consider the net in Figure 11. It is easy to observe that the relation \( R = \{(s_1, s_2), (s_3, \emptyset)\} \) is a \( d \)-place bisimulation, as for all the pairs \((m_1, m_2) \in R^\circ \), both markings are stuck, so that the \( d \)-place bisimulation game is vacuously satisfied.

Nonetheless, it is easy to observe that if a \( d \)-place bisimulation \( R \) relates a place \( s \) with non-empty post-set to \( \emptyset \), then it is not possible to find two transitions \( t_1 \) and \( t_2 \) such that for the proof of \((t_1^*, t_2^*) \in R^\circ \) it is necessary to use the pair \((s, \emptyset)\) (cf. the subsequent Example [10]. In other words, the condition \((t_1, t_2) \in R^\circ \) in Definition [18] is actually \((t_1^*, t_2^*) \in R^\circ \).

In order to prove that \( \sim_d \) is an equivalence relation, we now list some useful properties of \( d \)-place bisimulation relations, whose proof is omitted because very similar to that of the analogous Proposition [1].

Proposition 7. For each P/T net \( N = (S, A, T) \), the following hold:
The identity relation $\mathcal{R}_I^e = \{(r, r) \mid r \in S \cup \{\theta\}\}$ is a d-place bisimulation;  
2) the inverse relation $R^{-1} = \{(r', r) \mid (r, r') \in R\}$ of a d-place bisimulation $R$ is a d-place bisimulation;  
3) the relational composition $R_1 \circ R_2 = \{(r, r''') \mid \exists r' (r, r') \in R_1 \land (r', r'') \in R_2\}$ of two d-place bisimulations $R_1$ and $R_2$ is a d-place bisimulation.

Hence, in a standard way, we can prove that d-place bisimilarity $\sim_d$ is an equivalence relation, too.

6.1 D-place Bisimilarity Implies Fully-concurrent Bisimilarity

D-place bisimilarity $\sim_d$ is incomparable w.r.t. causal-net bisimilarity (cf. Example 8 and 9). However, we now show that $\sim_d$ does fully respect causality and branching time, by proving that $\sim_d$ implies fully-concurrent bisimilarity $\sim_{fc}$. Example 8 and the following one show that the implication is strict.

Example 10. Consider the net in Figure 12 Even if $s_1$ and $s_2 \oplus s_4$ are fully-concurrent bisimilar, we cannot find any d-place bisimulation relating these two markings. If we include the necessary pairs $(s_1, s_3)$ and $(\theta, s_4)$, then we would fail immediately, because the pair $(s_1, s_3)$ does not satisfy the d-place bisimulation game, as $s_1$ can move, while $s_3$ cannot.

Theorem 3. For each P/T net $N = (S, A, T)$, if $m_1 \sim_d m_2$ then $m_1 \sim_{fc} m_2$.

Proof: If $m_1 \sim_d m_2$, then there exists a d-place bisimulation $R_1$ such that $(m_1, m_2) \in R_1^\circ$. Let us consider

$$R_2 = \{((\pi_1, g, \pi_2), \pi_1 = (C_1, p_1)) \mid \pi_2 = (C_2, p_2) \text{ is a process of } N(m_2),$$

$g$ is an event isomorphism between $E_{C_1}$ and $E_{C_2}$,

$$(p_1(Max(C_1)), p_2(Max(C_2))) \in R_1^\circ, \text{ and } \forall e \in E_1, (p_1(e^*), p_2(g(e^*))) \in R_1^\circ \}.$$

We want to prove that $R_2$ is a fully-concurrent bisimulation.

First of all, consider a triple of the form $(\pi_1^i, g^i, \pi_2^i)$, where $C_i^0$ is the causal net without events and $p_1^i, p_2^i$ are such that $p_1^i(\text{Min}(C_i^0)) = p_2^i(\text{Max}(C_i^0)) = m_i$ for $i = 1, 2$ and $g^i$ is the empty function. Then $(\pi_1^i, g^0, \pi_2^i)$ must belong to $R_2$, because $(C_1^0, p_1^i)$ is a process of $N(m_1)$, for $i = 1, 2$, and, by hypothesis, $(m_1, m_2) \in R_1^\circ$. Hence, if $R_2$ is a fully-concurrent bisimulation, then the triple $(\pi_1^i, g^i, \pi_2^i) \in R_2$ ensures that $m_1 \sim_{fc} m_2$.

Now, assume $(\pi_1, g, \pi_2) \in R_2$. In order for $R_2$ to be an fcbisimulation, we must prove that

1) $\pi_2 \xrightarrow{e_2} \pi'_2$ with $p_2^i(e_2) = t_2$;  
2) $g' = g \cup \{(e_1, e_2)\}$, and finally,  
3) $(\pi_1, g', \pi_2) \in R_2$.

and symmetrically, if $\pi_2$ moves first.

Assume $\pi_1 = (C_1, p_1) \xrightarrow{e_1} (C_1', p_1') = \pi'_1$ with $p_1^i(e_1) = t_1$.

Recall that if $(\pi_1, g, \pi_2) \in R_2$, then $\forall e \in E_1, (p_1^i(e^*), p_2^i(g(e^*))) \in R_1^\circ$. For each event $e$, let $q_e = \{(r_1, r_1'), (r_2, r_2'), \ldots, (r_k, r_k')\}$, $k \geq 0$, be any multisets of associations that can be used to prove that $(p_1^i(e^*), p_2^i(g(e^*))) \in R_1^\circ$, with the property that for each $(r_1, r_1')$ in $q_e$, if $r_1 = p_1(b_1)$ for some $b_1 \in Max(C_1) \cap e^*$, then either $r_1' = \emptyset$, or there exists $b'_1 \in Max(C_1) \cap g(e^*)$ such that $r_1 = p_1(b'_1)$ and symmetrically, if $r_1' = p_1(b'_1)$ for some $b'_1 \in Max(C_1) \cap g(e^*)$, then either $r_1' = \emptyset$, or there exists $b'_1 \in Max(C_1) \cap e^*$. Now we filter out from $q_e$ exactly the sub-multiset $q'_e$ containing only those pairs $(r_1, r_1')$ in $q_e$ such that there exist $b_1 \in Max(C_1) \cap e^*$ and/or $b'_1 \in Max(C_2) \cap g(e^*)$ such that $r_1 = p_1(b_1)$ and/or $r_1' = p_1(b'_1)$. Finally, we make the multisets union of all these filtered multisets $q'_e$ of associations to get a multiset $q_e$ that can be used to prove that $(p_1(Max(C_1)), p_2(Max(C_2))) \in R_1^\circ$, with the property that for each $(r_1, r_1')$ in $q_e$, we have that either one of the two elements in the pair is $\emptyset$, or they are the image of conditions generated by events related by the event isomorphism $g$.

Now, let $p = \{(T_1, T'_1), \ldots, (T_n, T'_n)\} \subseteq q$, with $T_1 \oplus \cdots \oplus T_n = t_1$. Note that $(T'_1, T'_1 \oplus \cdots \oplus T'_n) \in R_1^\circ$. Since $R_1$ is a d-place bisimulation, there exists $t_2$ such that $t_2 = T_1 \oplus \cdots \oplus T_n \oplus l(t_1)$ such that $l(t_2), (t'_1, t'_2) \in R_1^\circ$. Therefore, because of the way the multiset $q_e$ has been constructed, it is possible to single out an event $e_2$, with $p_2^i(e_2) = t_2$, such that $\pi_2 = (C_2, p_2) \xrightarrow{e_2} (C_2', p_2') = \pi'_2$ (where $p_2'$ is such that $p_2'(e_2) = t_2$ and such that the set of events generating the conditions of $e_2$ (mapped by $p_1$ to $\pi_1$) are isomorphic, via $g$, to the set of events generating the conditions of $e_2$ (mapped by $p_2$ to $\pi_2$). Hence, the new generated events $e_1$ and $e_2$ have isomorphic predecessors via $g$. So, by defining $g' = g \cup \{(e_1, e_2)\}$, we conclude that $g'$ is an event isomorphism between $E_{C_1}$ and $E_{C_2}$.

Finally, from the multisets of associations $q$ we remove the associations in $p$ and add any multiset $p'$ of associations that can be used to prove that $(t'_1, t'_2) \in R_1^\circ$. This new multiset can be used to prove that $(p_1'(Max(C_1)), p_2'(Max(C_2))) \in R_1^\circ$.

Moreover, by construction we have that $(p_1'(e^*), p_2'(g(e^*))) \in R_1^\circ$, so that the last requirement in the definition of $R_2$ is satisfied also for the newly introduced pairs of events, as required. As a consequence $(\pi_1^i, g^i, \pi_2^i) \in R_2$.

The case when $\pi_2 = (C_2, p_2)$ moves first is symmetrical and therefore omitted. Thus, $R_2$ is a fully-concurrent bisimulation and, since $(\pi_1^i, g^i, \pi_2^i) \in R_2$, we have $m_1 \sim_{fc} m_2$.

6.2 D-place bisimilarity is decidable

Now, we follow the same steps of the decidability proof of $\sim_p$ to prove that also d-place bisimilarity is decidable.

Lemma 2. Given a P/T net $N = (S, A, T)$ and a relation $R \subseteq (S \cup \{\theta\}) \times (S \cup \{\theta\})$, it is decidable if $R$ is a d-place bisimulation.

1By the definition of d-place bisimilation, which preserves the size of the pre-set of matched transitions (cf. Example 9), it is not possible that, for a condition $b_1 \in Max(C_1) \cap e^*$, all the possible matching conditions $b'_1 \in g(e^*)$ are not maximal.
Proof: We want to prove that $R$ is a d-place bisimulation if and only if the following two conditions are satisfied:

1) $\forall t_1 \in T, \forall m \text{ such that } (t_1, m) \in R^\circ$
   
   (a) $\exists t_2 \text{ such that } m = \ast t_2$, with $l(t_1) = l(t_2)$ and $(t_1^*, t_2^*) \in R^\circ$.

2) $\forall t_2 \in T, \forall m \text{ such that } (m, t_2) \in R^\circ$
   
   (b) $\exists t_1 \text{ such that } m = \ast t_1$, with $l(t_1) = l(t_2)$ and $(t_1^*, t_2^*) \in R^\circ$.

The implication from left to right is obvious: if $R$ is a d-place bisimulation, then for sure conditions 1 and 2 are satisfied. For the converse implication, assume that conditions 1 and 2 are satisfied; then we have to prove that the d-place bisimulation game for $R$ holds for all pairs $(m_1, m_2) \in R^\circ$.

Let $g = \{(r_1, r_1'), (r_2, r_2'), \ldots, (r_k, r_k')\}$ be any multiset of associations that can be used to prove that $(m_1, m_2) \in R^\circ$. Note that some of the $r_i$ or of the $r_i'$ can be $\emptyset$. So this means that $m_1 = r_1 \oplus r_2 \oplus \ldots \oplus r_k$, $m_2 = r_1' \oplus r_2' \oplus \ldots \oplus r_k'$ and that $(r_i, r_i') \in R$ for $i = 1, \ldots, k$.

If $m_1(t_1) m_1'$, then $m_1' = m_1 \oplus t_1 \oplus t_1^*$. Consider any multiset of associations $p = \{t_1, t_1', \ldots, t_h, t_h'\} \subseteq g$, with $t_1 \oplus \ldots \oplus t_h = t_1^*$. Note that $(t_1^*, t_1') \in R^\circ$. Therefore, by condition 1, there exists a transition $t_2$ such that $t_2 = t_1 \oplus \ldots \oplus t_h, l(t_1) = l(t_2)$ and $(t_1^*, t_2^*) \in R^\circ$. Hence, since $t_2 \subseteq m_2$, also $m_2(t_2)m_2'$ is wifiable, where $m_2 = m_2 \oplus t_2 \oplus t_2^*$, so that $(t_1^*, t_2^*) \in R^\circ$, $(t_1^*, t_2^*) \in R^\circ$, $l(t_1) = l(t_2)$ and, finally, $(m_1 \oplus \ast t_1, m_2 \oplus \ast t_2) \in R^\circ$, as required. Note that the last condition holds because, from the multiset $g$ of matching pairs for $m_1$ and $m_2$, we have removed those in $p$.

If $m_2(t_2)m_2'$, then we have to use an argument symmetric to the above, where condition 2 is used instead. Hence, we have proved that conditions 1 and 2 are enough to prove that $R$ is a place bisimulation.

Finally, the complexity of this procedure is analogous to that in Lemma 11.

Theorem 4. (D-place bisimilarity is decidable) Given a P/T net $N = (S, A, T)$, for each pair of markings $m_1$ and $m_2$, it is decidable whether $m_1 \sim_d m_2$.

Proof: Since $S$ is finite, the set of all the place relations over $S \cup \{\emptyset\}$ is finite as well. Let us list all the place relations as follows: $R_1, R_2, \ldots, R_n$. Therefore, for $i = 1, \ldots, n$, by Lemma 2 we can decide whether the place relation $R_i$ is a d-place bisimulation and, in such a case, we can check whether $(m_1, m_2) \in R^\circ$ in $O(k^2 \sqrt{n})$ time, where $k$ is the size of the largest marking. As soon as we have found a d-place bisimulation $R_i$ such that $(m_1, m_2) \in R^\circ$, we stop concluding that $m_1 \sim_d m_2$. If none of the $R_i$ is a d-place bisimulation such that $(m_1, m_2) \in R^\circ$, then we can conclude that $m_1 \sim_d m_2$.

Of course, also this procedure is exponential in the size of the net.

7 AN EVEN COARSER DECIDABLE EQUIVALENCE, NOT RESPECTING CAUSALITY

Place bisimilarity is not the coarsest equivalence proposed in [3]. In fact, the coarsest equivalence relation proposed in that paper, called i-place bisimilarity, is as follows.

Definition 19. (I-place bisimulation) Let $N = (S, A, T)$ be a P/T net. An i-place bisimulation is a relation $R \subseteq S \times S$ such that if $(m_1, m_2) \in R^\circ$ then

1) $\forall t_1 \in T, \forall m \text{ such that } (t_1, m) \in R^\circ$
   
   (a) $\exists t_2 \text{ such that } m = \ast t_2$, with $l(t_1) = l(t_2)$ and $(t_1^*, t_2^*) \in R^\circ$.

2) $\forall t_2 \in T, \forall m \text{ such that } (m, t_2) \in R^\circ$
   
   (b) $\exists t_1 \text{ such that } m = \ast t_1$, with $l(t_1) = l(t_2)$ and $(t_1^*, t_2^*) \in R^\circ$.

Two markings $m_1$ and $m_2$ are i-place bisimilar, denoted by $m_1 \sim_i m_2$, if there exists an i-place bisimulation $R$ such that $(m_1, m_2) \in R^\circ$.

In other words, $R \subseteq S \times S$ is an i-place bisimulation if $R^\circ$ is an interleaving bisimulation. Also $\sim_i$ is an equivalence relation and can be proved decidable with a variation of the proof technique of Section 5. In fact, it is easy to prove that $R$ is an i-place bisimulation if and only if the following two finite conditions are satisfied:

1) $\forall t_1 \in T, \forall m \text{ such that } (t_1, m) \in R^\circ$
   
   (a) $\exists t_2 \text{ such that } m = \ast t_2$, with $l(t_1) = l(t_2)$ and $(t_1^*, t_2^*) \in R^\circ$.

2) $\forall t_2 \in T, \forall m \text{ such that } (m, t_2) \in R^\circ$
   
   (b) $\exists t_1 \text{ such that } m = \ast t_1$, with $l(t_1) = l(t_2)$ and $(t_1^*, t_2^*) \in R^\circ$.

However, i-place bisimilarity is not very satisfactory, because, even if it respects the branching time, it does not respect causality.

Example 11. Let us consider the net in Figure 13 whose transitions are $t_1 = (s_1, a, \emptyset), t_2 = (s_2, b, \emptyset), t_3 = (s_3, a, \emptyset), t_4 = (s_4, b, \emptyset)$ and $t_5 = (s_3 \oplus s_4, a, s_4)$. Let us consider relation $R = \{(s_1, s_3), (s_2, s_4)\}$, which is clearly an i-place bisimulation (but not a place bisimulation). In particular, $(s_1 \oplus s_2, s_3 \oplus s_4) \in R^\circ$, transition $s_3 \oplus s_4$ is matched by $s_1 \oplus s_2 \oplus t_1$, and transition $s_4 \oplus t_4$ is matched by $s_2 \oplus t_2 \emptyset$. However, in these computations $s_4 \oplus s_5$ generates the partial order where $a$ and $b$ are independent, while $s_3 \oplus s_4$ generates the partial order where $b$ is caused by $a$.

Nonetheless, $\sim_i$ implies step bisimilarity $\sim_{si}$, so that i-place bisimulation markings exhibit the same potential parallelism (cf. the subsequent Theorem 5). As a matter of fact, markings $s_1 \oplus s_2$ and $s_3 \oplus s_4$ of the nets in Figure 13 are the typical example of two markings that are step bisimilar, but not ST bisimilar [11, 21], a finer behavioral equivalence which, as discussed in [14], is the coarsest equivalence to be real-time consistent, meaning that for every association of execution times to actions, assuming that actions happen as soon as they can, the running times associated with computations from equivalent markings should be the same. So, i-place bisimilarity, besides not respecting causality, it is not even real-time consistent, as it does not imply ST bisimilarity. (On the contrary, [14] argues that place bisimilarity is real-time consistent, and the same can be argued for d-place bisimilarity.)
Of course, it is possible to define an even coarser decidable equivalence by allowing for a place to be related to the empty marking, θ, as for d-place bisimilarity, yielding i-d-place bisimilarity.

**Definition 20. (i-d-place bisimulation)** Let \( N = (S, A, T) \) be a P/T net. An i-d-place bisimulation is a relation \( R \subseteq (S \cup \{\theta\}) \times (S \cup \{\theta\}) \) such that if \((m_1, m_2) \in R^\circ\) then

- \( \forall l_1 \in T, \forall m_1 \in \mathbb{R} \) such that \( (l_1, m_1) \in R^\circ \)
  - \( \exists l_2 \) such that \( m_2(l_2) m_2' \), with \( l(t_1) = l(t_2) \) and \( (m_2', m_2') \in R^\circ \).

- \( \forall l_2 \) such that \( m_2(l_2) m_2' \), \( \exists l_1 \) such that \( m_1(l_1) m_1' \), with \( l(t_1) = l(t_2) \) and \( (m_1', m_1') \in R^\circ \).

Two markings \( m_1 \) and \( m_2 \) are i-d-place bisimilar, denoted by \( m_1 \sim_{id} m_2 \), if there exists an i-d-place bisimulation \( R \) such that \( (m_1, m_2) \in R^\circ \).

In other words, \( R \subseteq (S \cup \{\theta\}) \times (S \cup \{\theta\}) \) is an i-d-place bisimulation if \( R^\circ \) is an interleaving bisimulation. Of course, also i-d-place bisimilarity \( \sim_{id} \) is an equivalence relation, slightly coarser than \( \sim \), and can be proved decidable with yet another variant of the proof technique in Sections 5 and 6.2. Indeed, it is easy to see that a relation \( R \) is an i-d-place bisimulation if and only if the following two finite conditions are satisfied:

1. \( \forall l \in T, \forall m \in \mathbb{R} \) such that \( (l, m) \in R^\circ \)
   - \( \exists l' \) such that \( m(l') m' \), with \( l(t) = l(t) \) and \( (l', m') \in R^\circ \).

2. \( \forall l \in T, \forall m \in \mathbb{R} \) such that \( (m, l) \in R^\circ \)
   - \( \exists l' \) such that \( m(l') m' \), with \( l(t) = l(t) \) and \( (l', m') \in R^\circ \).

Actually, \( \sim_{id} \) is the coarsest equivalence relation proposed so far which is decidable on finite Petri nets. To conclude, we prove that \( \sim_{id} \) implies step bisimilarity \( \sim_s \), so that, even if causality is not respected, at least the concurrent behavior is preserved.

**Theorem 5.** For each \( P/T \) net \( N = (S, A, T) \), if \( m_1 \sim_{id} m_2 \) then \( m_1 \sim_s m_2 \).

**Proof:** If \( m_1 \sim_{id} m_2 \), then there exists an i-d-place bisimulation \( R \) such that \( (m_1, m_2) \in R^\circ \). We want to prove that \( R^\circ \) is a step bisimulation, i.e., that \( (m_1, m_2) \in R^\circ \) then

- \( \forall G \) such that \( m_1(G_1) m_1' \), \( \exists G_2 \) such that \( m_2(G_2) m_2' \) with \( l(G_1) = l(G_2) \) and \( (m_1', m_2') \in R^\circ \).

- \( \forall G_2 \) such that \( m_2(G_2) m_2' \), \( \exists G_1 \) such that \( m_1(G_1) m_1' \) with \( l(G_1) = l(G_2) \) and \( (m_1', m_2') \in R^\circ \).

To make the presentation lighter, we assume that \( G_1 \) is composed of two transitions only, say \( \{t_1, t_2\} \). The general case when the size of \( G \) is \( n \) is only notionally more complex, but not more difficult conceptually.

Assume \( m_1(\{t_1, t_2\}) m_1' \). This means that \( t_1 \oplus t_2 \subseteq m_1 \). Hence, \( m_1 = t_1 \oplus t_2 \oplus m_1 \) and \( m_1 = t_1 \oplus t_2 \oplus m_1 \). Since \( (m_1, m_2) \in R^\circ \), we may find \( m_1, m_2, m_2' \) such that \( m_2 = m_1 + m_1  \oplus m_2 \) and, moreover, that \( (t_1, m_1) \in R^\circ \), \( (t_2, m_2) \in R^\circ \) and \( (m_1, m_1) \in R^\circ \). Since \( R \) is an i-place bisimulation, from \( (t_1, m_1) \in R^\circ \) it follows that there exists \( l_1 \) such that \( l_1(t_1) m_1' \), with \( l(t) = l(t) \) and \( (l_1', m_1') \in R^\circ \); similarly, from \( (t_2, m_2) \in R^\circ \) it follows that there exists \( l_2 \) such that \( l_2(t_2) m_2' \), with \( l(t) = l(t) \) and \( (l_2', m_2') \in R^\circ \). Therefore, \( m_2[l_1', l_2'] m_2' = m_1 + m_1  \oplus m_2 \), such that \( (m_1', m_2') \in R^\circ \) follows by additivity.

The case when \( m_2 \) moves first is symmetric, hence omitted. Therefore, \( R^\circ \) is a step bisimulation.

8 CONCLUSION AND FUTURE RESEARCH

Place bisimilarity seems a very natural behavioral equivalence for finite P/T Petri nets, which respects the expected causal behavior, as it is slightly finer than causal-net bisimilarity [19], (or, equivalently, structure preserving bisimilarity [14]), in turn slightly finer than fully-connceputal bisimilarity [3]. Significantly, to date, it is the first sensible (i.e., fully respecting causality and branching time) behavioral equivalence which has been proved decidable for finite P/T nets (with the relevant exception of net isomorphism), even if its complexity is exponential in the size of the net. Thus, it is the only equivalence for which it is possible (at least, in principle) to verify algorithmically the (causality-preserving) correctness of a distributed system by exhibiting a place bisimulation between its specification Petri net and its implementation Petri net.

It is sometimes argued that place bisimilarity is too discriminating. In particular, [2] and [14] argue that a sensible equivalence should not distinguish markings whose behaviors are patently the same, such as marked Petri nets that differ only in their unreachable parts. As an example, consider the net in Figure 14 originally presented in [2]. Clearly, markings \( s_1 \) and \( s_4 \) are equivalent, also according to all the behavioral equivalences discussed in [14], except for place bisimilarity. As a matter of fact, a place bisimulation \( R \) containing the pair \((s_1, s_4)\) would require also the pairs \((s_2, s_3)\) and \((s_5, s_6)\), but then this place relation \( R \) cannot be a place bisimulation because \((s_2 \oplus s_3 \oplus s_5 \oplus s_6) \in R^\circ \), but \( s_2 \oplus s_3 \) can perform \( c \), while this is not possible for \( s_5 \oplus s_6 \). Nonetheless, we would like to argue in favor of place bisimilarity, despite this apparent paradoxical example.

As a matter of fact, our interpretation of place bisimilarity is that this equivalence is an attempt of giving semantics to unmarked nets, rather than to marked nets, so that the focus shifts from the common (but usually undecidable) question *When are two markings equivalent?* to the more restrictive (but decidable) question *When are two places equivalent?* A possible (preliminary, but not accurate enough) answer to the latter question may be: two places are equivalent if, whenever the same number of tokens are put on these two places, the behavior of the marked nets is the same. If we reinterpret the example of Figure 14 in this perspective, we clearly see that place \( s_1 \) and place \( s_4 \) cannot be considered as equivalent because, even if the markings \( s_1 \) and \( s_4 \) are equivalent, nonetheless the marking \((s_1, s_4)\) is not equivalent to the marking \((s_2, s_4)\), as only the former can perform the trace \( abc \).

A place bisimulation \( R \) considers two places \( s_1 \) and \( s_2 \) as equivalent if \((s_1, s_2) \in R\), as, by definition of place bisimulation, they must behave the same in any R-related context. Back to our example in Figure 14 if \((s_1, s_4)\) would belong to \( R \), then also \((2 \cdot s_1, 2 \cdot s_4)\) should belong to \( R^\circ \), but then we discover that the
place bisimulation game does not hold for this pair of markings, so that $R$ cannot be a place bisimulation.

Moreover, there are at least the following three important technical differences between place bisimilarity and other coarser, causality-respecting equivalences, such as fully-concurrent bisimilarity [5].

1) A fully-concurrent bisimulation is a complex relation – composed of cumbersome triples of the form (process, bijection, process) – that must contain infinitely many triples if the net system offers never-ending behavior. (Indeed, not even one single case study of a system with never-ending behavior has been developed for this equivalence.) On the contrary, a place bisimulation is always a very simple finite relation over the finite set of places. (And a tiny case study is outlined in Example 6)

2) A fully-concurrent bisimulation proving that $m_1$ and $m_2$ are equivalent is a relation specifically designed for the initial markings $m_1$ and $m_2$. If we want to prove that, e.g., $n \cdot m_1$ and $n \cdot m_2$ are fully-concurrent bisimilar (which may not hold!), we have to construct a new fully-concurrent bisimulation to this aim. Instead, a place bisimulation $R$ relates those places which are considered equivalent under all the possible $R$-related contexts. Hence, if $R$ justifies that $m_1 \sim_p m_2$ as $(m_1, m_2) \in R^\oplus$, then for sure the same $R$ justifies that $n \cdot m_1$ and $n \cdot m_2$ are place bisimilar, as also $(n \cdot m_1, n \cdot m_2) \in R^\oplus$.

3) Finally, while place bisimilarity is decidable, fully-concurrent bisimilarity is undecidable on finite P/T nets with at least two unbounded places [10].

One further criticism against place bisimilarity $\sim_p$ may be that its complexity is too high to be useful in practice. However, on the one hand, we would like to observe that essentially all the decidable properties over unbounded finite P/T nets are at least exponential; for instance, about the reachability problem (i.e., deciding whether a given marking is reachable from the initial marking). Lipton proved an exponential space lower bound (EXPSPACE-hard) [27], and none of the algorithms known so far is primitive recursive (cf., e.g., [28]). On the other hand, we conjecture that our decision procedure can be improved. In fact, future work will be devoted to find more efficient algorithms for checking place bisimilarity. One idea could be to build directly the set of maximal place bisimulations – starting from the unique maximal equivalence place bisimulation (that can be easily computed [3]) and then elaborating on it, as we did in Example 4 and 5 – rather than to scan all the place relations to check whether they are place bisimulations, as we did in the proof of Theorem 2. Moreover, if the goal is not that of computing the equivalence relation $\sim_p$, but simply to prove that two specific markings, say $m_1$ and $m_2$, are place bisimilar, one can simply try to build one particular place bisimulation $R$ such that $(m_1, m_2) \in R^\oplus$ (as we did for the tiny case studies of Example 6 and 7), which seems a much simpler task.

We have proposed a slight weakening of place bisimilarity $\sim_p$, called $d$-place bisimilarity $\sim_d$, which may relate places to the empty marking $\theta$ and which is still decidable. Actually, we conjecture that $d$-place bisimilarity is the coarsest, sensible equivalence relation which is decidable on finite P/T nets (without silent moves). D-place bisimilarity is still slightly finer than fully-concurrent bisimilarity.

On the subclass of BPP nets (i.e., nets whose transitions have singleton pre-set), place bisimilarity coincides with team bisimilarity [17], which is actually coinductive and, for this reason, efficiently decidable (in polynomial time, by using a generalization of, e.g., the Kanellakis-Smolka’s algorithm [24]), characterized by a simple modal logic, and even axiomatizable over the process algebra BPP with guarded summation and guarded recursion [16]. Team bisimilarity is unquestionably the most appropriate behavioral equivalence for BPP nets, as it coincides with structure-preserving bisimilarity [14], hence matching all the relevant criteria expressed in [14] for a sensible behavioral equivalence. Moreover, d-place bisimilarity specializes to $h$-team bisimilarity [19], which coincides with fully-concurrent bisimilarity on this subclass of P/T nets.

We have also discussed that place bisimilarity is not the coarsest decidable equivalence for Petri nets proposed in [3]. In fact, we have proved that i-place bisimilarity $\sim_i$ is still decidable, even if not satisfactory as it does not respect causality. For the sake of exposition completeness, we have observed that the newly proposed variant i-d-place bisimilarity $\sim_{i-d}$ is an even coarser decidable equivalence relation, that is the coarsest decidable equivalence defined so far on finite Petri nets respecting the branching time and the concurrent behavior (as it is finer than step bisimilarity $\sim_s$), but not respecting causality.

Extensions of the theory presented in this paper have been sketched in [20], where the decidable branching place bisimilarity has been proposed for finite P/T nets with silent moves (taking inspiration from branching bisimilarity on LTSs [13]), and also in [7], where the decidable $pi$-place bisimilarity has been proposed for the Turing-complete model of finite Petri nets with inhibitor arcs [11, 24]. Future work will be devoted to deepen the study of these extensions and to experimentally show the usefulness of the place bisimulation framework over some complex case studies.
