**ABSTRACT:** *Mesosphaerum suaveolens* (L.) Kuntze is a species of high phytotherapeutic and aromatic potential and quite widespread in Northeastern Brazil. However, the scarcity of good quality water and the high content of salts contained in the soil and irrigation water of the semi-arid region can compromise the crop growth and yield. Therefore, this study aimed to evaluate the effect of seed treatment with salicylic acid on the growth rates and the fluorescence indexes of chlorophyll ‘a’ from *M. suaveolens* plants irrigated with saline waters. The experiment was conducted in a randomized complete block design with a 5 x 5 incomplete factorial design, with five electrical conductivities of the irrigation water (ECw = 0.5, 1.45, 5.00, 8.55 and 10.0 dS m⁻¹) and five salicylic acid doses (SA = 0.0, 0.29, 1.0, 1.71 and 2.0 mM L⁻¹), generated by the Box Central Compound matrix. The evaluated variables were the absolute and relative growth rates for stem height and diameter and the indexes of fluorescence and quantum yield of photosystem II. The salinity of the water reduces the growth and the fluorescence indexes of the plants. The seeds treatment with salicylic acid at the doses of 1.99 and 0.69 mM L⁻¹ attenuates the damaging effect from saline stress on the absolute and relative growths for the stem diameter.

**Key words:** growth reducer; medicinal species; salinity; seed treatment

**Taxas de crescimento e fluorescência de *Mesosphaerum suaveolens* (L.) Kuntze sob estresse salino e doses de ácido salicílico**

**RESUMO:** *Mesosphaerum suaveolens* (L.) Kuntze é uma espécie de elevado potencial fitoterápico e aromático e bastante difundida no Nordeste brasileiro. Porém, o elevado teor de sais contidos no solo e na água de irrigação da região semiárida podem comprometer o crescimento e produtividade da cultura. Assim, objetivou-se avaliar o efeito do tratamento de sementes com ácido salicílico nas taxas de crescimento e índices de fluorescências da clorofila ‘a’ de plantas de alfazema irrigadas com águas salinas. O experimento foi conduzido em delineamento de blocos casualizados, em esquema fatorial incompleto 5 x 5, com cinco níveis condutividade elétrica da água de irrigação (CEa= 0,5; 1,45; 5,00; 8,55 e 10,0 dS m⁻¹) e cinco doses de ácido salicílico (AS= 0,0; 0,29; 1,0; 1,71 e 2,0 mM L⁻¹), geradas pela matriz Composto Central de Box. Foram avaliadas as variáveis de taxas de crescimento absoluto e relativo para a altura e diâmetro do caule e os índices de fluorescência e o rendimento quântico do fotosistema II. A salinidade da água reduz o crescimento e os índices de fluorescência das plantas. O tratamento das sementes de ácido salicílico nas doses de 1,99 e 0,69 mM L⁻¹ atenua o efeito danoso do estresse salino sobre o crescimento absoluto e relativo para o diâmetro do caule.

Introduction

The *Mesosphaerum suaveolens* (L.) Kuntze, part of the Lamiaceae family, has herbal and aromatic properties used in traditional medicine. This crop is considered as a multipurpose species due to its biological properties and antifungal, insecticidal and anti-inflammatory actions (Figueirêdo et al., 2018). The main utility of this plant is the production of an essential oil rich in phytotherapeutic compounds, however, its growth and production of biomass and oil vary according to the cultivation conditions (Arruda et al., 2018).

Since the *M. suaveolens* is a species that demonstrates favorable conditions in adapting to the Brazilian Northeastern semi-arid and for its use in the popular medicinal of the region, the crop shows potential to be explored. However, the Northeast region is characterized by containing high salt content in both the soil and the waters used in irrigation, with compromising reflexes on the crops productive capacity. The high salt content sometimes is not that high; however, when above the level tolerated by the crop, it causes growth inhibition and interferes negatively in the plant physiology and biomass formation (Bezerra et al., 2018).

As according to Silva et al. (2013), salinity harms plants in two forms overall, by reducing the soil osmotic potential, with increased saline content resulting in greater energy expenditure in absorbing water and nutrients; and by the phytotoxicity of specific ions such as sodium, boron, bicarbonates and chloride, which disturbs the physiological and biochemical processes.

In plants under stress conditions, such as the saline case, the fluorescence indexes of chlorophyll ‘a’ are important in estimating the damage caused to the photosynthesis. This is because they allow evaluating the physiological condition of the photosystem II and the electron transport chain, as well as the damage caused by salt stress on the photosynthetic apparatus (Kalaji et al., 2016).

Due to serious problems regarding soil salinity or irrigation water, researchers in the area are striving for techniques that minimize or reduce the damage from salt stress on the plant growth. Among these, the use of phytohormones stands out, acting on the plant growth regulation; such as the case of the salicylic acid, for example, a phenolic compound that function acting on the plant growth regulation; such as the case of the growth. Among these, the use of phytohormones stands out, acting on the plant growth regulation; such as the case of the salicylic acid, for example, a phenolic compound that function acting on the plant growth regulation; such as the case of the

The different electrical conductivities were obtained by adding sodium chloride (NaCl) to the water of the supply system (ECw = 0.5 dS m⁻¹) in the required proportions, with the values assessment aided by portable conductivimeter of the microprocessor-style model, Instrutherm® (model CD-860). Irrigations were daily, from 10 days after sowing, with the water volume applied established through drainage lysimetry, found by the difference in the amount of water applied and drained (Alves et al., 2017).

The seeds were treated with salicylic acid by diluting its doses in 200 mL of distilled water and soaking the seeds in this solution for a period of 8 hours inside plastic containers, kept at a mean temperature of 25.2 °C and relative humidity of around 54.2%. Afterwards the imbibition period, the seeds were washed with distilled water in order to remove acid excess.

The used seeds were all obtained from native plants located in the Novo Horizonte settlement, municipality of Várzea - PB. The experiment was conducted in polyethylene bags with capacity for 1.2 dm³, where 10 seeds were sown per bag, with thinning held after the emergence establishment, around 10 days after sowing, leaving only one plant per vessel.

The vessels were filled with substrate formulated from the mixture of a “Latosolosso” (Oxisol) soil type, washed sand and tanned bovine manure in the 3:1:1 proportion (Embrapa, 2018), with its chemical composition displayed in Table 1.

In order to determine the growth rates, two evaluations were performed at 15 and 45 days, with their involved variables calculated as the following:

### Materials and Methods

The experiment was conducted in a greenhouse, part of the Department of Phytotechnics and Environmental Sciences of the Agricultural Sciences Center, Federal University of Paraíba (CCA/UFPB), Campus II, Areia - Paraíba.

The experimental design used was the randomized complete block in a 5 x 5 incomplete factorial design, referring to five levels of electrical conductivities of the irrigation water (ECw: 0.5; 1.45; 5.0; 8.55 and 10.0 dS m⁻¹) and five salicylic acid doses (0.0; 0.29; 1.0; 1.71 and 2.0 mM L⁻¹), with four replicates composed of two plants, generated by the experimental matrix Box Central Compound (Mateus et al., 2001).

### Table 1. Chemical characterization of the substrate used in the experiment.

| pH | O.M. (g kg⁻¹) | P (mg kg⁻¹) | K⁺ | Ca²⁺ | Mg²⁺ | Na⁺ | SB (cmol dm⁻³) | H⁺+Al³⁺ | Al³⁺ | CEC |
|----|---------------|-------------|----|------|------|-----|----------------|---------|-------|-----|
| 7.8| 22.2          | 85.5        | 693.6 | 2.9  | 1.59 | 0.23 | 6.5            | 0.0     | 0.0   | 6.5 |

O.M. = organic matter; SB = saturation of bases; CEC = cation exchange capacity.
- Rates of absolute and relative growth for height and diameter of the stem: established from adapting the methodology previously described by Benincasa (2003), according to the equations 1 and 2:

\[
\text{AGRHp} = \frac{(A_p - A_p)}{(t_2 - t_1)} \quad \text{AGRD} = \frac{(D_2 - D_1)}{(t_2 - t_1)}
\]

In which: AGRHp = absolute growth rate for the plant height; AGRD = absolute growth rate for the stem diameter; Ap1 and D1 = value of the evaluation 15 days after applying saline waters; Ap2 and D2 = height value of the evaluation 45 days after applying saline waters; t1 = number of days of the first evaluation (15 days); t2 = number of days of the second evaluation (45 days).

\[
\text{RGRHp} = \frac{(\ln A_p - \ln A_p)}{(t_2 - t_1)} \quad \text{RGRD} = \frac{(\ln D_2 - \ln D_1)}{(t_2 - t_1)}
\]

In which: RGRHp = relative growth rate for the plant height; RGRD = relative growth rate for the stem diameter; lnAp1 and lnD1 = natural logarithm from the value of the evaluation 15 days after applying saline waters; lnAp2 and lnD2 = natural logarithm from the value of the evaluation 45 days after applying saline waters; t1 = number of days of the first evaluation (15 days); t2 = number of days of the second evaluation (45 days).

The evaluation of chlorophyll fluorescence variables was with the aid of a modulated fluorometer (Sciences Inc. - Model OS-30p, Hudson, USA). Clamps for leaves were placed for 30 minutes before the reading to adapt the leaves to the dark, with the initial fluorescence (F0), maximum fluorescence (Fm), variable fluorescence (Fv = Fm - F0), Fv/F0 ratio and the quantum yield of the photosystem II (Fv/Fm).

The data were subjected to the analysis of variance by the F test (p > 0.05) and by regression, employing the SAS University statistical program for processing data (Cody, 2015).

**Results and Discussion**

The interaction between the different electrical conductivities of the irrigation water and the salicylic acid doses promoted a significant effect on the rates of absolute and relative growth of the stem diameter (Table 2). ECw had a significant isolated effect on the rate of absolute and relative growth of the plant height. The salicylic acid doses influenced the absolute growth rate regarding the plant height.

The absolute growth rate of the stem showed the largest increments (0.18) in plants submitted to seed treatment at a 1.99 mM L⁻¹ dose of SA and irrigated with water of 0.5 dS m⁻¹ EC (Figure 1A). As for the relative growth rate, the maximum increments (0.18) were reached for the treatment with the highest salicylic acid doses and water salinity (Figure 1B).

**Table 2.** Summary of the analysis variance of the absolute (AGRH) and relative (RGRH) growth rates for plant height, absolute (AGRD) and relative (RGRD) growth rates for stem diameter of *Mesosphaerum suaveolens* (L.) Kuntze plants subjected to salicylic acid doses and irrigation water salinity.

SV = sources of variation; DoF = degrees of freedom; NS, ** and * = not significant, significant at 1 and 5% by F test, respectively.
values (0.029) were obtained at the 0.69 mM L⁻¹ dose and at 0.5 dS m⁻¹ salinity (Figure 1B). This behavior indicates the SA action in the cell division process, enabling a greater plant growth. SA promotes cellular protection under stress conditions, thus favoring the integrity of the DNA and RNA membranes and acting on the signaling against stress conditions, as with the case of osmotic adjustment and control of stomatal opening, allowing the plant to hold its vital processes (Feitosa et al., 2016).

The effect of exogenous SA application on the plant growth was observed by other authors, such as Fayez & Bazaid (2014), who found that applying 50 μM of SA attenuated the effect of salt stress and increased the growth of barley plants (*Hordeum vulgare* L.). Nazar et al. (2015) verified that the 0.5 mM L⁻¹ dose of SA mitigated the effect of salt stress, stimulating photosynthesis, growth and biomass production in mustard plants (*Brassica juncea* L.). Sultan & Mohamed (2016) promoted an increased growth of cucumber (*Cucumis sativus* L.) by treating its seeds with 0.07 and 0.18 mM L⁻¹ of AS. Silva et al. (2018) found that applying 1.0 mM L⁻¹ of SA favored the growth of basil (*Ocimum basilicum* L.).

As for the absolute and relative growths, the data from plant height and stem diameter were reduced as a function of the increasing salinity of the irrigation water, with the values fitting to the decreasing linear model (Figure 2). The relative and absolute growth rates, for plant height, also followed the largest increments in plants subjected to a lower ECw (0.5 dS m⁻¹), succeeded by severe reductions with the increasing salinity, reaching decreases up to 52 and 21%, respectively (Figure 2A and 2B). Damage caused by salt stress on the cell turgor pressure reduces the water content in the tissues, thus resulting in the decline of both cell expansion and the growth of tomato - *Lycopersicum esculentum* L. (Freire et al., 2010).

The effect of the salicylic acid doses on the absolute growth rate of height demonstrated results that best fit to the quadratic model, with a maximum increment of 1.05 in the 0.9 mM L⁻¹ dose of SA (Figure 2C). The acid acts by regulating the cell cycle and secondary plant metabolism, as well as energy expenditure in the catalyst pathways and in the assimilation rates of the resulting compounds, accumulating them mainly in the plant shoot, making a greater resistance to abiotic stress conditions possible and favoring the growth (Napoleão et al., 2017).

Regarding the fluorescence indexes of chlorophyll ‘α’, Table 3 reveals that there was no significant effect for the interaction between the factors and neither for the salicylic acid doses. On the other hand, the irrigation water salinity promoted an effect on maximum and variable fluorescence, the quantum yield of photosystem II and the ratio between variable and initial fluorescence.

The variable and maximum fluorescences were similar, with their values fitting to the decreasing linear effect as the ECw increased, with the highest means in the 0.5 dS m⁻¹ salt level, with 649.64 and 790.41 quantum electrons⁻¹, respectively (Figure 3A and 3B). The increasing ECw promoted severe reductions, reaching up to 61% and 50% when comparing the salinity results of the lowest with the highest (10 dS m⁻¹). This effect demonstrates that the high salt content causes severe

SV = sources of variation; DoF = degrees of freedom; * , ** and * = not significant, significant at 1 and 5% by F test, respectively.

**Figure 3.** Variable fluorescence - Fᵥ (A), maximum fluorescence - Fₘ (B), ratio between maximum and initial fluorescence - Fᵥ/F₀ (C) and quantum yield of photosystem II - Fᵥ/Fₘ (D) in Mesosphaerum suaveolens (L.) Kuntze plants subjected to different irrigation water salinities.

In a likely manner, the variables Fᵥ and Fₘ behaved as the ratio between maximum and initial fluorescence (Fᵥ/F₀) did, where plants irrigated with water of 0.5 dS m⁻¹ EC had the highest values (4.94 quantum electrons⁻¹) followed by high decreases with the increasing ECw, obtaining a reduction of 62% in the salinity of 10 dS m⁻¹ (Figure 3C). This decrease due to the increasing ECw indicates that the salt stress promotes great damages to the photosynthetic apparatus and the damage to the photosynthetic apparatus, corroborating to the CO₂ assimilation rate response. These results are indicative that salinity affects the photochemical efficiency, reducing the exchange of electrons among the photosystems and reducing the photochemical activity of the leaves (Lima et al., 2019), thus, plants promote the slowing down of the photosynthetic process as a mechanism for mitigating the salt stress toxic effects (Silva et al., 2014).
efficiency of CO₂ carboxylation. This, associated with the negative effect promoted by the salts excess to chlorophyll and on the synthesis of ATP and NADPH, result in low yield and photosynthetic efficiency (Dias et al., 2018).

In a similar fashion, the quantum yield of photosystem II (Fv/Fm) had results that fitted to the decreasing linear model, with losses that reached 23% when comparing the values of plants subjected to lower and higher ECw, emphasizing the damage caused by salt stress (Figure 3D). The reduction in the quantum yield of photosystem II is indicative of damage to the photosynthetic apparatus, where the salinity can inhibit the breakdown of the water molecules needed for the chemical stage of the process, acting directly on photosystem II (Oliveira et al., 2018).

Conclusions

The seeds treatment with salicylic acid attenuates the damaging effect of irrigation water salinity on the growth of *Mesosphaerum suaveolens* (L.) Kuntze plants;

The absolute and relative growth rates for the stem diameter are stimulated by the salicylic acid doses of 1.99 and 0.69 mM L⁻¹;

The increased electrical conductivity of irrigation water compromises the growth rates and fluorescence levels of chlorophyll ‘a’ in *M. suaveolens* plants.
